Preface

- Purpose of the Book
- Approach and Organization

Acknowledgments

Unit 1 Foundations for Health Promotion

1 Health Defined

- Exploring Concepts of Health
- Health
- Illness, Disease, and Health
- Planning for Health
- Healthy People 2020
- Levels of Prevention
- The Nurse's Role
- Improving Prospects for Health
- Shifting Problems
- Moving Toward Solutions
- Tying It All Together Using the Nursing Process
- Summary
- References

2 Emerging Populations and Health

- Health Disparities and Health Equality
- Emerging Populations in the United States
- Ethnicity, Ethnic Group, Minority Group, and Race
- Culture, Values, and Value Orientation
- Cultural Competency
- Folk Healing and Nursing Care Systems
- Arab Americans
- Asian Americans/Pacific Islanders

Latino/Hispanic Americans

Black/African Americans

American Indians/Alaska Natives

The Emerging Rural and Urban Populations: Homeless Persons

The Nation's Response to the Health Challenge

Nursing's Response to Emerging Populations and Health

Summary

References

3 Health Policy and the Delivery System

The Health of the Nation

A Safer System

Global Health

History of Health Care

Organization of the Delivery System

Financing Health Care

Health Care Systems of Other Countries

Summary

Preface

Purpose of the Book

The case for promoting and protecting health, and preventing disease and injury, was established by many accomplishments in the 20th century and continued into the 21st century. Americans and global populations are taking better care of themselves; public concerns about physical fitness, good nutrition, and avoidance of health hazards such as smoking have become adopted in the lifestyles of global citizens. Encouraging positive health changes has been a major effort of individuals, the government, health professionals, and society in general. In the United States, public and private attempts to improve the health status of individuals and groups traditionally have focused on reducing communicable diseases and health hazards. Concerns continue about how to deliver the best practices to improve access to and reduce costs of health services and to improve the overall quality of life for all people. Americans increasingly recognized that the health of each individual is influenced by the health environments of all individuals worldwide.

Throughout the history of the United States, the public health community has assessed the health of Americans. In 1789, the Reverend Edward Wigglesworth developed the first American mortality tables through his study in New England. Population statistics gathered in England and America, including those of Florence Nightingale, proved that useful data could change health outcomes. The *Report of a General Plan for the Promotion of Public and Personal Health* was completed by Lemuel Shattuck in 1880. *Healthy People, The Surgeon General's Report on Health Promotion and Disease Prevention,* was first published in 1979, and was followed by *Healthy People 2000: National Health Promotion and Disease Prevention Objectives,* which listed three goals:

- Increase the span of healthy life for Americans.
- Reduce health disparities among Americans.
- Achieve access to preventive services for all Americans.

These original documents were followed by *Healthy People 2010* and *2020*.

Health-promotion advances require a better understanding of the environment, health risks, behaviors, and intervention measures. *Healthy People 2010* identified important determinants of health status, which included:

- Individual behavior
- Biology and genetics
- Physical environment
- Social environment
- Health services

Outcome measures designed to assist individual and group efforts to change and improve behavior in these areas can lead to decreases in morbidity and mortality.

Professionals who undertake health-promotion strategies also need to understand the basics of health protection and disease and injury prevention. Health protection is directed at population groups of all ages and involves adherence to standards, outcomes, infectious disease control, and governmental regulation and enforcement. The focus of these activities is on reducing exposure to various sources of hazards, including those related to air, water, foods, drugs, motor vehicles, and other physical agents.

Health care providers present individuals, families, and communities with disease- and injury-prevention services, which include immunizations, screenings, health education, and counseling. To implement prevention strategies effectively, it is essential to develop activities targeted to and tailored for all age groups in various settings including schools, industries, the home, the health care delivery system, the larger community, and the world. *Healthy People 2010* addressed these health problems by establishing goals and objectives for the first decade of the new millennium. The vision for *Healthy People 2010* was "Healthy people in healthy communities" because, as nursing has long recognized, the health of each individual is inseparable from the health of families, communities, nations, and

the world. Health is significantly affected by the environment in which each individual lives, works, travels, and plays. Dimensions of the environment are not only physical but also psychosocial and spiritual; including the behaviors, attitudes, and beliefs of each individual. Specific objectives in 28 focus areas supported 2 major goals:

- Increase quality and years of healthy life.
- Eliminate health disparities.

Released in 2010, *Healthy People 2020* reflects the earlier assessments of major risks to health, changing public health priorities, and emerging issues related to our nation's health preparedness and prevention. The following vision was established: A society in which all people live long healthy lives.

The mission within this vision is improving health through strengthening policy. *Healthy People 2020* will:

- Identify nationwide health improvement priorities.
- Increase public awareness and understanding of the determinants of health, disease, and disability and the opportunities for progress.
- Provide measurable objectives and goals that can be used at the national, state, and local levels.
- Engage multiple sectors to take action that are driven by the best available evidence and knowledge.
- Identify critical research and data collection needs.

The overarching goals for *Healthy People 2020* continue the tradition of earlier *Healthy People* initiatives of advocating for improvements in the health of every person in our country. They address the environmental factors and place particular emphasis on the determinants of health:

- Eliminate preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health

for all.

- Promote healthy development and healthy behaviors across every stage of life.

The databases within *Healthy People* continue to indicate targets and assessments of health status and risk for evaluations and future planning, not only for health policymakers and health care providers but also for individuals, families, and communities at the local, regional, national, and global levels. (Subscribe to the *Healthy People* listserv for the latest information and to receive e-mail notices of related news, events, and publications at http://healthypeople.gov/hp2020.)

The information in this edition of *Health Promotion Throughout the Life Span* includes these and other data and guidelines for health promotion, health protection, preventive services, and surveillance data systems, including those to the US Preventive Services Task Force (www.ahrq.gov/clinic/cps) and the Guide to Community Preventive Services (www.thecommunityguide.org).

Approach and Organization

This edition presents health data with related theories and skills that are needed to understand and practice when providing care. This book focuses on primary prevention intervention; its three main components are: (1) health promotion, (2) specific health protection, and (3) prevention of specific diseases. Health promotion is the intervention designed to improve health, such as providing adequate nutrition, a healthy environment, and ongoing health education. Specific protection and prevention strategies, such as massive immunizations, periodic examinations, and safety features in the workplace, are the interventions used to protect against illness.

In addition to primary prevention, this book discusses secondary prevention interventions, focusing specifically on screening and education. Such programs include blood pressure, cholesterol, and diabetes screening and referral (the acute components of secondary prevention are generally not addressed in this book).

This text is presented in five parts, each forming the basis for the next.

Unit 1, *Foundations for Health Promotion,* describes the foundational concepts of promoting and protecting health, and preventing diseases and injuries, including diagnostic, therapeutic, and ethical decision-making.

Unit 2, *Assessment for Health Promotion,* focuses on individuals, families, and communities and the factors affecting their health. The functional health pattern assessments developed by Gordon serve as the organizing framework for assessing the health of individuals, families, and communities.

Unit 3, *Interventions for Health Promotion,* discusses theories, methodologies, and case studies of nursing interventions, including screening, health-education counseling, stress management, and crisis intervention.

Unit 4, *Application of Health Promotion,* also uses Gordon's functional health patterns, emphasizing developmental, cultural, ethnic, and

environmental variables in assessing the developing person. The intent is to address the health concerns of all Americans regardless of gender, race, age, or sexual orientation. Although most human development theories discussed are primarily based on the research of male subjects, newer theories based on female subjects are included. The hope is to describe human development that more accurately reflects the complexity of human experiences throughout the life span.

Unit 5, *Emerging Global Health Issues,* presents a single chapter that discusses changing population groups and their health needs as well as related implications for research and practice in the 21st century. Throughout the text, research abstracts have been added to highlight the science of nursing practice and to demonstrate to the reader the relationship among research, practice, and outcomes.

Throughout these units, the evolving health care professions and the changing health care systems, including future challenges and initiatives for health promotion, are described. Emphasis is placed on the current concerns of reducing health care costs while increasing life expectancy and improving the quality of life for all Americans. This promotes the reader's immediate interest in thoughts about the content of the chapters.

Key Features

- A **full-color design,** including color photos, is implemented throughout for better accessibility of content and visual enhancement.
- Each chapter starts with a list of **objectives** to help focus the reader and emphasize the content the reader should acquire through reading the book.
- **Key Terms** including quality and safety terms are listed at the front to acquaint readers with the important terminology of the chapter.
- Each chapter's narrative begins with a **Think About It** section, the presentation of a clinical issue or scenario that relates to the topic of the chapter, followed by critical thinking questions. This promotes the reader's immediate interest in and thought about the chapter.

- **Research for Evidence-Based Practice** boxes provide brief synopses on current health-promotion research studies that demonstrate the links between research, theory, and practice.
- **Diversity Awareness** boxes offer cultural perspectives on various aspects of health promotion.
- **Quality and Safety** boxes provide information regarding specific scenarios to improve health.
- **Genomics** boxes explore current genetic issues, controversies, and dilemmas with respect to health promotion, providing an opportunity for critical analysis of care issues.
- **Innovative Practice** boxes highlight inventive and resourceful projects, programs, and research studies that draw upon new ways of implementing health promotion.
- ***Healthy People 2020*** boxes present a list of selected objectives that are relevant to each chapter's topic.
- The **Case Study** highlights a real-life clinical situation relevant to the chapter topic.
- The **Care Plan** relates to the Case Study with the standardized sections of Defining Characteristics, Related Factors, Expected Outcomes, and Interventions, and details nursing diagnoses relevant to health-promotion activities and the related interventions.
- **Study Questions** are located on the book's website to offer additional review and self-study practice.

New Features

1. An increased focus on genomics reflects increasing scientific evidence supporting the health benefits of using genetic tests and family health history to guide public health interventions.

2. The latest information about The Patient Protection and Affordable Care Act is included.

3. Expanded discussion of QSEN competencies related to health

promotion.

4. Guidelines and recommendations from the latest Guide to Clinical Preventive Services, issued by the US Preventive Services Task Force, is included as appropriate.

5. Updated photos bring a fresh look and feel to the text.

Evolve Resources

The expanded website for this book provides materials for both students and faculty, and is accessible at http://evolve.elsevier.com/Edelman/.

For Students

- **Study Questions:** Multiple choice NCLEX® examination format

For Instructors

- **TEACH for Nurses,** including Nursing Curriculum Standards, Teaching Activities, and Case Studies
- **Image Collection,** with all images from the book
- **Lecture Slides,** in PowerPoint
- **Test Bank,** 700 questions in NCLEX® examination format

The current trend to emphasize the developing health of people mandates that health care professionals understand the many issues that surround individuals, families, national and world communities in social, work, and family settings, including biological, inherited, cognitive, psychological, environmental, and sociocultural factors that can put their health at risk. Most important is that they develop interventions to promote health by understanding the diverse roles these factors play in the person's beliefs and health practices, particularly in the areas of disease and injury prevention, protection, and health promotion. Achieving such effectiveness requires collaboration with other health care providers and the integration of

practice and policy while developing interventions and considering the ethical issues within individual, family, and both national and world communities' responsibilities for health.

Carole Lium Edelman

Elizabeth Connelly Kudzma

Acknowledgments

We had the good fortune of receiving much assistance and support from many friends, relatives, and associates. Our colleagues read chapters, gave valuable advice and criticism, helped clarify concepts, and provided case examples.

We also acknowledge the contributions of all the authors. In developing this text, they gave the project their total commitment and support. Their professional competence aided greatly in the development of the final draft of the manuscript. The editors worked and learned from each other during the planning and development of this book; throughout the entire process, close contact prevailed. Elizabeth Kudzma, a long-standing contributor, is the co-editor of this edition. She has added much knowledge and perspective to the ninth edition.

Many thanks to the Elsevier editorial and production team: Charlene Ketchum, Jamie Blum, Mary Pohlman, and Jeffrey Patterson. We appreciate and thank them for their ongoing help and support. It is a true pleasure working with them.

I am fortunate to have faith in the Lord, who gives courage and strength to face life's difficulties in a positive manner. My children, John and Megan Gillespie, Tom and Heather Gillespie, and Deirdre O'Brien, and my grandchildren, Ryan, Caroline, Meredith, and Colleen, bring joy to me as a mother and grandmother. Their patience and love are truly appreciated. Fredric Edelman provides much encouragement and support. Both my brother and sister in law, John and Marilyn Lium, are inspirational to me and a reminder every day that health in life is precious.

Carole Lium Edelman

As a contributor from the first edition to the present, I thank Carole Edelman for inviting me to become a co-editor of this ninth edition. The insights and clinical experiences of Curry College faculty colleagues and students are continuing sources of enrichment. Thanks also to my family, including my sister and brother (Mary and Mark), daughter Katherine, and especially to my husband Daniel, who provided support, discussion, and insight throughout this project.

Elizabeth Connelly Kudzma

4 The Therapeutic Relationship
5 Ethical Issues Related to Health Promotion

Health Defined

Health Promotion, Protection, and Prevention

Ratchneewan Ross, Carolyn Cable Kleman

OBJECTIVES

After completing this chapter, the reader will be able to:

- Analyze concepts and models of *health* as used historically and as used in this textbook.
- Evaluate the consistency of *Healthy People 2020* goals with various concepts of health.
- Analyze the progress made in this nation from the original Healthy People document to the foci in *Healthy People 2020*.
- Differentiate between health, illness, disease, disability, and premature death.
- Compare the four levels of prevention (primordial, primary, secondary, and tertiary) with the levels of service provision available across the life span.
- Critique the role of research and evidence as well as the nurse's role in health education and research for the promotion and protection of health for individuals and populations.

Think About It

Use of Complementary and Alternative Therapies

One of the biggest challenges to health care providers is the blending of Western medicine and health practices with the health practices from other cultures and ethnic groups. The federal government formed the National Center for Complementary and Alternative Medicine (NCCAM; http://nccam.nih.gov) to conduct and support basic and applied research and training and to disseminate information on complementary and alternative medicine to practitioners and the public. As demographics of the United States shift, more people use a combination of therapies in self-care and for the treatment of specific illnesses.

- What questions should the student ask to obtain information from people about their use of nontraditional therapies?
- What information should the student know about the benefits or limitations of using complementary therapies, such as acupuncture, spiritual healing, herbal remedies, or chiropractic?
- What resources should the student trust for information on the efficacy and use of herbal remedies relative to prescription medications?

- Which ideas of health would be most compatible with the use of alternative therapies?
- How can alternative therapies be integrated into *Healthy People 2020* objectives, given that the emphasis of these objectives is the use of available community resources and the development of partnerships?

Health is a core concept in society. This concept is modified with qualifiers such as *excellent, good, fair,* or *poor,* on the basis of a variety of factors. These factors may include age, sex, race or ethnic heritage, comparison group, current health or physical condition, past conditions, social or economic situation, geographical location, or the demands of various roles in society. In addition, there is growing evidence that larger societal and environmental concerns determine health outcomes. This chapter will discuss health as a concept and related concepts such as wellness, illness, disease, disability, and functioning. These concepts are frequently embedded in theories, such as theories of health behavior (Pender et al., 2015) or health planning (Issel, 2014). Some motivating factors behind the move to disease prevention and health promotion in society will be examined with an introduction to *Healthy People 2020,* the federal government's health objectives for the nation. The implementation of these concepts as nursing actions will also be addressed from ideal and pragmatic standpoints. Research and evidence supporting these concepts, and recommendations for further research, will be presented.

Nurses understand the pivotal role they play in promoting health and preventing disease, the important role of research in the knowledge of what is "healthy," and the central role of **epidemiology** (the study of health and disease in society) and public health theories in the everyday practice of nursing.

Exploring Concepts of Health

Dr. Margaret Newman (2003), a nursing theorist, states that definitions of health in the nursing literature can be classified broadly within two major paradigms. The first paradigm is the **wellness-illness continuum,** a dichotomized portrayal of health and illness ranging from high-level wellness at the positive end to depletion of health at the negative end. **High-level wellness** is further conceptualized as a sense of **well-being,** life satisfaction, and **quality of life.** Movement toward the negative end of the continuum includes adaptation to disease and disability through various levels of functional ability. The wellness-illness conceptualization was the focus of early research and is consistent with some of the categories Smith (1983) identified in her philosophical analysis of health. Research based on this paradigm conforms primarily to scientific methods that seek to control contextual effects, provide the basis for causal explanations, and predict future outcomes (see, Kaplow and Reed, 2008).

The second paradigm characterizes health as a perspective developmental phenomenon of unitary patterning of the person-environment. The developmental perspective of health has been present in the nursing literature since 1970, but it was not identified clearly with health until the late 1970s and early 1980s. It has been conceptualized as expanding consciousness, pattern or meaning recognition, personal transformation, and, tentatively, self-actualization. This shift toward a developmental perspective has had clear implications for the way in which health is conceptualized (Newman, 2003). Although not endorsing the developmental perspective to the extent of Rogers (1970) and Reed (1983), Pender and colleagues (2015) and Allen and Warner (2002) state that health is an outcome of ongoing patterns of person and environment interactions throughout the life span. Research within this paradigm seeks to address the dynamic whole of the health experience through behavioral and social mechanisms over time. Health can be better

understood if each person is seen as a part of a complex, interconnected biological and social system.

The **ecological model of health** (Institute of Medicine, 2003) is a comprehensive developmental approach, and is useful for promoting health at individual, family, community, and societal levels. This model was updated in 2008 (and the 2010 report adding quality of life) with an emphasis on the **social determinants of health**—those factors in society that have an influence on health and the options available to people to improve or maintain their health. (These models are also reviewed in Richard et al., 2011.) In this way, the ecological model of health is more compatible with Smith's descriptions of health as adaptation and eudemonia (self-actualization). The social determinants of health also form the basis for *Healthy People 2020* (US Department of Health and Human Services [USDHHS], Office of Disease Prevention and Health Promotion, 2011). Each of these ideas will be examined in more detail throughout this chapter.

People involved in health promotion must consider the meaning of health for themselves and for others. Recognizing differences in the meaning of health can clarify outcomes and expectations in health promotion and enhance the quality of health care. Because health is used to describe a number of entities, including a philosophy of care (health promotion and health maintenance), a system (health care delivery system), practices (evidence-based health practices), behaviors (personal health behaviors), costs (health care costs), and insurance (uninsured health care), the reason that confusion continues regarding the use of the term "health" becomes clear. People's use of the term "health," and its incorporation into these various entities, has also changed over time.

Americans born before 1940 experienced the greatest changes in how health is defined. Because infectious diseases claimed the lives of many children and young adults at that time, health was viewed as the absence of disease. The physician in independent practice was the primary provider of health care services, with services provided in the private office. The federal government was only beginning to establish its role in working with states to address public health and welfare

issues (Barr et al., 2003).

As the national economy expanded during and after World War II in the 1940s and 1950s, the idea of role performance became a focus in industrial research and entered the health care lexicon. Health became linked to a person's ability to fulfill a role in society. Increasingly, the physician was asked to complete physical examination forms for school, work, military, and insurance purposes, while physician practice became linked more directly to hospital-based services. The federal government expanded its role through funding for hospital expansion and establishment of the new Department of Health, Education, and Welfare, currently the Department of Health and Human Services (Barr et al., 2003). It was recognized that a person might recover from a disease yet be unable to fulfill family or work roles because of residual changes from the illness episode. Concepts of disability and rehabilitation entered the health care arena. The work or school environment was viewed as a possible contributor to health, illness, disability, and death.

From the 1960s to the present, there have been incredible changes in the health care delivery system while federal and state governments attempted to control spending and health care costs escalated (Barr et al., 2003). Primary care providers, including nurse practitioners and other advanced practice nurses, now attempt to involve individuals and their families in the delivery of **person-centered care,** and teaching individuals about individual responsibilities and lifestyle choices has become an important part of their job. Health care became an interdisciplinary endeavor even while managed care companies limited the health-promotion options available under insurance plans. During this time the idea of adaptation had an important influence on the way Americans view health. Increasingly, health became linked to individuals' reactions to the environment rather than being viewed as a fixed state. Adaptation fit well with the self-help movement during the 1970s and with the progressive growth in knowledge from research of disease prevention and health promotion at the individual level.

Emphasis is being placed on the quality of a person's life as a

component of health (USDHHS, Public Health Service, 2000; USDHHS, Office of Disease Prevention and Health Promotion, 2011). Research on self-rated health (Cano et al., 2003; Idler & Benyamini, 1997) and self-rated function (Greiner et al., 1999) indicates that there are multiple factors contributing to a person's perception of his or her health, sometimes referred to as **functional health** (Gordon, 2016) or **health-related quality of life (HRQoL)** (Andresen et al., 2003; USDHHS, Office of Disease Prevention and Health Promotion, 2011). Multiple tools are available for measuring quality of life, including a general measure established by the World Health Organization (2004) (World Health Organization Quality of Life, WHOQOL-BREF) and the McGill Quality of Life Questionnaire (Cohen et al., 1997) for use at the end of life (Box 1-1: Quality and Safety Scenario).

Box 1-1

Quality and Safety Scenario

Fall Prevention in the Home

Falls in the home are a common yet preventable source of both fatal and nonfatal injuries. In 2012, the Centers for Disease Control and Prevention reported in its *Morbidity and Mortality Weekly Report* QuickStats section that older adults aged 75 years or older had the most nonfatal injury falls in which health care providers were consulted because of the injury. These data, from the 2010 National Health Interview Survey, indicate that 12% of this older adult population experience a fall significant enough to seek health care.

There are specific factors that contribute to fall risk, including changes to the person attributable to age, medication use, and environmental hazards. Nurses are in key roles to work with older adults to assess fall risks and help them gain control over this aspect of their health. The National Center for Injury Prevention and Control at the Centers for Disease Control and Prevention provides guidelines for fall prevention in older adults at http://www.cdc.gov/ncipc/pub-res/toolkit/checklistforsafety.htm.

Risk factors attributable to the aging process include visual, hearing, and functional limitations. Although pets have proven to be a benefit for older adults by providing companionship and comfort, they can also scamper underfoot or the older adult may trip over the pet because the pet is not seen or heard. Loss of night vision and depth perception can also contribute to falls when lighting is poor or when a person is moving from room to room. Older adults should be encouraged to always wear prescribed vision and hearing aids when moving about the house or apartment. Loss of upper and lower body strength can also contribute to fall risk. Lower body strength is needed to lift the legs and feet high enough to navigate stairs and changes in texture of flooring. Upper body strength allows the use of supports when a person is moving about. Watch the person maneuver about the living space and note the use of furniture, walls, and other objects for support.

Medications can contribute to disequilibrium. A careful review of currently used medications, both prescribed and over-the-counter medications, can help identify medications that could possibly contribute to fall risks. Environmental risks include clutter, too much furniture for the room, placement of items in typical walkways, lighting problems, needed repairs to flooring and walls, and the need for supports such as grab bars and railings. Again, watching the person navigate through the home is helpful in recognizing potential trip hazards and areas where additional supports are needed. Adequate hydration is another consideration, especially if the person is taking medications that contribute to dehydration without regular fluid replacement or if the temperature of the home and environment is too high.

Health outcomes for the person can be significant. Falls can cause minor injury and embarrassment, but they can also cause life-threatening injuries such as fractures and head injuries. If a fall has occurred, it is helpful to do a root cause analysis to determine those factors that contributed to the fall. Ask permission before attempting to make any alteration to the home, because items and their placement may have sentimental importance to the person. Address

medication changes with the person, pharmacist, and/or primary care provider. Some medication habits may be hard for the person to change.

The nursing implications of fall risk are many and varied. Assessment skills must be practiced in a variety of settings so that the nurse is vigilant for potential hazards and individual factors that might precipitate a fall. Older adults should be routinely observed performing their daily routines to identify visual, hearing, and functional decline. Also, if a person reports a fall, that report should trigger a more extensive evaluation of that individual because falls may be indicative of future fall risk.

Falls are a frequent but preventable occurrence, especially for older adults. Falls also contribute millions of dollars each year to the cost of health care as a result of personal injury and disability. That is why fall prevention is a key feature of quality and safety education for nurses.

Questions

- Can you identify at least four items in your own environment that may contribute to your fall risk?
- How would you structure an interview with an older adult to determine the presence of fall risks in that person's home?
- What evidence and arguments would you use to encourage an older adult to modify the home environment to decrease the risk of a fall?

Models of Health

Throughout history, society has entertained a variety of concepts of health (David, 2000). Smith (1983) describes four distinct models of

health in her classic work.

Clinical Model

In the clinical model, health is defined by the absence of signs and symptoms of disease and illness is defined by the presence of signs and symptoms of disease. People who use this model may not seek preventive health services or they may wait until they are very ill to seek care. The clinical model is the conventional model of the discipline of medicine.

Role Performance Model

The **role performance model of health** defines health in terms of individuals' ability to perform social roles. Role performance includes work, family, and social roles, with performance based on societal expectations. Illness would be the failure to perform roles at the level of others in society. This model is the basis for occupational health evaluations, school physical examinations, and physician-excused absences. The idea of the "sick role," which excuses people from performing their social functions, is a vital component of the role performance model. It is argued that the sick role is still relevant in health care today (Burnham, 2012; Davis et al., 2011).

Adaptive Model

In the **adaptive model of health,** people's ability to adjust positively to social, mental, and physiological change is the measure of their health. Illness occurs when the person fails to adapt or becomes maladaptive to these changes. As the concept of adaptation has entered other aspects of American culture, this model of health has become more accepted. For example, spirituality can be useful in adapting to a decreased level of functioning in older adults (Haley et al., 2001).

Eudaimonistic Model

In the eudaimonistic model, exuberant well-being indicates optimal health. This model emphasizes the interactions between physical, social, psychological, and spiritual aspects of life and the environment that contribute to goal attainment and create meaning. Illness is reflected by a denervation or languishing, a lack of involvement with life. Although these ideas may appear to be new when compared with the **clinical model of health,** aspects of the eudaimonistic model predate the clinical model of health. This model is also more congruent with integrative modes of therapy (National Institutes of Health, National Center for Complementary and Alternative Medicine, 2011), which are used increasingly by people of all ages in the United States and the rest of the world. In this eudaimonistic model, a person dying of cancer may still be healthy if that person is finding meaning in life at this stage of development.

These ideas of health provide a basis for how people view health and disease and how they view the roles of nurses, physicians, and other health care providers. For example, in the clinical model of health, a person may expect to see a health care provider only when there are obvious signs of illness. Personal responsibility for health may not be a motivating factor for this individual because the provider is responsible for dealing with the health problem and returning the person to health. Therefore attempts to teach health-promoting activities may not be effective with this person. On the other hand, those who adopt a **eudaimonistic model of health** may find that practitioners working under a clinical model do not address their more comprehensive health needs. They may instead seek out a practitioner of alternative medicine or the counsel of a priest, rabbi, or minister to complement the services of the more traditional health provider.

Wellness-Illness Continuum

The wellness-illness continuum, as stated earlier, is a dichotomous depiction of the relationship between the concepts of health and illness. In this paradigm, **wellness** is a positive state in which incremental increases in health can be made beyond the midpoint

(Figure 1-1). These increases involve improved physical and mental health states. The opposite end of the continuum is illness, with the possibility of incremental decreases in health beyond the midpoint. This depiction of the relationship of wellness and illness fits well with the conceptual and clinical model of health (McMahon & Fleury, 2012).

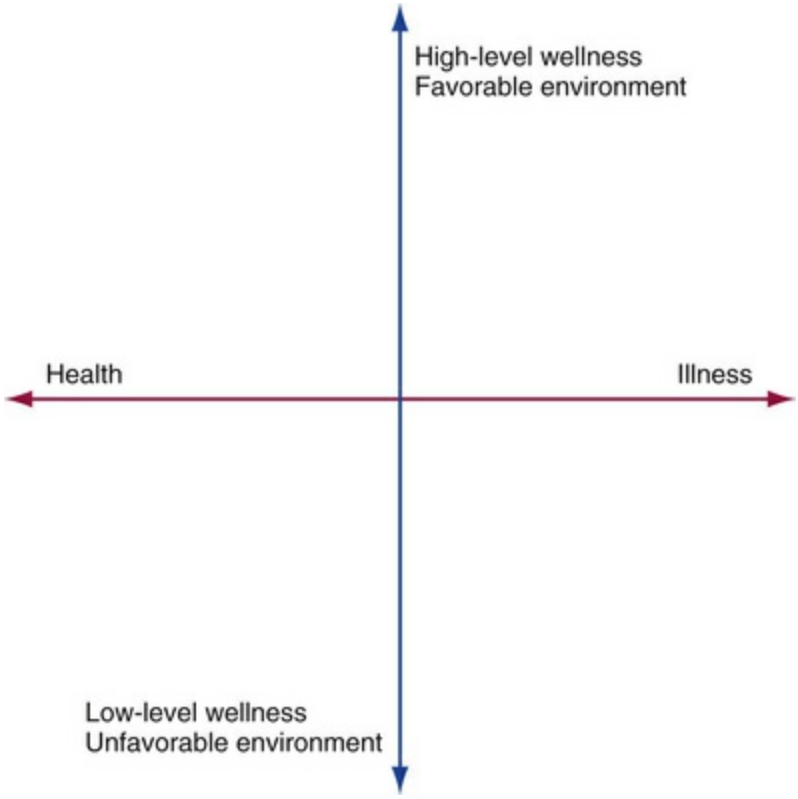

FIGURE 1-1 Wellness-illness continuum with high-level wellness added. Moving from the center to the right demonstrates movement toward illness. Moving from the center to the left demonstrates movement toward health. Moving above the line demonstrates movement toward increasing wellness. Moving below the line demonstrates movement toward decreasing wellness. (Modified from US Department of Health and Human Services, Public Health Service, (1982); McMahon, S., & Fleury, J. (2012). Wellness in older adults: A concept analysis. *Nursing Forum, 47*(1), 39–51.)

High-Level Wellness

From a dichotomous representation of health and illness as opposites, Dunn (1961) developed a health-illness continuum that assessed a person not only in terms of his or her relative health compared with that of others but also in terms of the favorability of the person's environment for health and wellness (see Figure 1-1). Adding this second dimension to the health-illness continuum created a matrix in which a favorable environment allows high-level wellness to occur and an unfavorable environment allows low-level wellness to exist.

With this addition, it became possible to combine the clinical model of health with models based on social and environmental parameters. The concept demonstrates that a person can have a terminal disease and be emotionally prepared for death, while acting as a support for other people and achieving high-level wellness. High-level wellness involves progression toward a higher level of functioning, an open-ended and ever-expanding future with its challenge of fuller potential and the integration of the whole being (Ardell, 2007). This definition of high-level wellness contains ideas similar to those in the eudaimonistic model of health. Additionally, high-level wellness emphasizes the interrelationship between the environment and the ability to achieve health on both a personal and a societal level.

Health Ecology

An evolving view of health recognizes the interconnection between people and their physical and social environments. Newman (2003) expressed this interconnection within a developmental framework, and the work of Gordon (2016) applies this interconnection to functional health patterns as presented in subsequent chapters. Health from an ecological perspective is multidimensional, extending from the individual into the surrounding community, and including the context within which the person functions. It incorporates a systems approach within which the actions of one portion of the system affect the functioning of the system as a whole (Institute of Medicine, 2003, 2010). This view of health expands on high-level wellness by

recognizing that there are social and environmental factors that can enhance or limit health and healthy behaviors. For example, most people can benefit from physical activity such as walking, and people are more likely to walk in areas where there are sidewalks or walking paths and where they feel safe. Nurses can encourage people to walk but may also need to advocate safe areas for people to walk and work with others to plan for people-friendly community development.

Functioning

One of the defining characteristics of life is the ability to function. Functional health can be characterized as being present or absent, having high-level or low-level wellness, and being influenced by neighborhood and society. Functioning is integral to health. There are physical, mental, and social levels of function, and these are reflected in terms of performance and social expectations. Function can also be viewed from an ecological perspective, as in the example of walking used previously. Loss of function may be a sign or symptom of a disease. For example, sudden loss of the ability to move an arm or leg may indicate a stroke. The inability to leave the house may indicate overwhelming fear. In both cases the loss of function is a sign of disease, a state of ill health. Loss of function is a good indicator that the person may need nursing intervention. Research in older adults indicates that decline in physical function is a sentinel event and may indicate the future loss of physical function and death (Boltz et al., 2012; Greiner et al., 1996).

Health

Health, as defined in this text, is a state of physical, mental, spiritual, and social functioning that realizes a person's potential and is experienced within a developmental context. Although health is, in part, an individual's responsibility, health also requires collective action to ensure a society and an environment in which people can act responsibly to support health. The culture and beliefs of people can also influence health action. This definition is consistent with the World Health Organization (WHO) definition of health as the state of complete physical, mental, and social well-being and not merely the absence of disease and infirmity (World Health Organization, 2004), but moves beyond this definition to encompass spiritual, developmental, and environmental aspects over time. The physical aspect includes one's genetic makeup, which when combined with the other aspects influences one's longevity. This broader definition is applicable across the life span, as well as in situations where illness may be a chronic state. For example, in this broader definition of health, a person with diabetes may be considered healthy if he or she is able to adapt to his or her illness and live a meaningful, spiritually satisfying life. Health is considered to be part of the metaparadigm for nursing (Fawcett & Garity, 2009), which includes the four components of person, health, environment, and nursing. As can be seen in the discussion thus far, health can be viewed in a variety of ways.

Illness, Disease, and Health

It is easy to think of health or wellness as the lack of disease and to consider "illness" and "disease" as interchangeable terms. However, "health" and "disease" are not simply antonyms and "disease" and "illness" are not synonyms. Disease literally means "without ease." **Disease** may be defined as the failure of a person's adaptive mechanisms to counteract stimuli and stresses adequately, resulting in functional or structural disturbances. This definition is an ecological concept of disease, which uses multiple factors to determine the cause of disease rather than describing a single cause. This multifactorial approach increases the chances of discovering multiple points of intervention to improve health.

Illness is composed of the subjective experience of the individual and the physical manifestation of disease (Hollingsworth & Didelot, 2005). Both are social constructs in which people are in an imbalanced, unsustainable relationship with their environment and are failing in their ability to survive and create a higher quality of life. Illness can be described as a response characterized by a mismatch between a person's needs and the resources available to meet those needs. Additionally, illness signals to individuals and populations that the present balance is not working. Within this definition, illness has psychological, spiritual, and social components. A person can have a disease without feeling ill (e.g., asymptomatic hypertension). A person can also feel ill without having a diagnosable disease (e.g., as a result of stress). Our understanding of disease and illness within society, overlaid with our understanding of the natural history of each disease, creates a basis for promoting health.

Planning for Health

Public health has always had the prevention of disease in society as its focus. However, during the past 30 years, the promotion of health and individual responsibility moved to the forefront within public health, becoming a driving force in health care reform.

A key milestone in promoting health was the advent of Healthy People (US Department of Health, Education, and Welfare, Public Health Service, 1979), the first Surgeon General's report on health promotion and disease prevention issued in the later years of President Carter's administration. This document identified five national health goals addressing the reduction of death in adults and children and the reduction of sick days in older adults.

- To continue to improve infant health, and, by 1990, to reduce infant mortality by at least 35%, to fewer than 9 deaths per 1000 live births.
- To improve child health, foster optimal childhood development, and, by 1990, reduce deaths among children aged 1 to 14 years by at least 20%, to fewer than 34 deaths per 100,000 children.
- To improve the health and health habits of adolescents and young adults, and, by 1990, to reduce deaths among people aged 15 to 24 years by at least 20%, to fewer than 93 deaths per 100,000 people.
- To improve the health of adults, and, by 1990, to reduce deaths among people aged 25 to 64 years by at least 25%, to fewer than 400 deaths per 100,000 people.
- To improve the health and quality of life for older adults, and, by 1990, to reduce the average annual number of days of restricted activity attributable to acute and chronic conditions by 20%, to fewer than 30 days per year for people aged 65 years or older.

Further, the document identified three causes of the major health issues in the United States as allowing careless habits, environmental pollution, and harmful social conditions (e.g., hunger, poverty, and ignorance) to persist that destroy health, especially for infants and children.

Healthy People was a call to action and an attempt to set health goals for the United States for the next 10 years. Unfortunately, a change in political leadership, a lack of political and social willpower, and the spiraling costs of hospital-based health care intervened. The need to report progress toward these national objectives led a larger, renewed effort in the form of *The 1990 Health Objectives for the Nation: A Midcourse Review* (USDHHS, Public Health Service, 1986). This midcourse review noted that, although many goals were achievable, the unachieved goals were hindered by current health status, limited progress on risk reduction, difficulties in data collection, and a lack of public awareness.

Healthy People 2000 (USDHHS, Public Health Service, 1990) and *Healthy People 2000 Midcourse Review and 1995 Revisions* (USDHHS, Public Health Service, 1996) were landmark documents in that a consortium of people representing national organizations worked with US Public Health Service officials to create a more global approach to health. Additionally, a management-by-objectives approach was used to address each problem area. These two documents became the blueprints for each state as funding for federal programs became linked to meeting these national health objectives. While the objectives became more widely implemented, methods for collecting data became formalized, and the data flowed back into the system to form the revisions set in 1995. The core of these health objectives remained: that is, prevention of illness and disease was the foundation for health. *Healthy People 2000* established three broad goals:

- Increase the span of healthy life.
- Reduce **health disparities.**
- Create access to preventive services for all.

Additionally, the work included 22 specific areas for achievement, with objectives in each area based on age, health disparities, and health needs. By 1995, progress was made on 70% of the objectives. However, for 30% of the objectives, movement toward the goals was in the wrong direction, had experienced no change, or could not be determined because of a lack of data.

Healthy People 2010 (USDHHS, Public Health Service, 2000) introduced two overarching goals:

- Increase quality and years of healthy life.
- Eliminate health disparities.

The first goal addressed the issues of longevity and quality of life. Both longevity and quality of life address the concern that people are living longer but frequently with numerous chronic health problems that interfere with the quality of their lives. However, quality of life is also an issue for people who are unable to achieve a long life. Combining these two ideas placed an emphasis on both longevity and quality of life as areas that need improvement.

The second goal, eliminating health disparities, addressed the continuing problems of access to care; differences in treatment based on race, gender, and ability to pay; and related issues such as urban versus rural health, insurance coverage, Medicare and Medicaid reimbursement for care, and satisfaction with service delivery.

From these goals, the *Final Report of the Commission on Social Determinants of Health* (Commission on Social Determinants of Health, 2008) was completed with the 733 objectives (of the original 969 objectives) for which tracking data were available. A total of 23% of these objectives were met, with another 48% moving toward their targets, representing positive responses on 71% of the objectives. However, 5% of the objectives demonstrated no change from the baseline, and 24% of the objectives moved in a negative direction from the target. For example, look at Focus Area 19: Nutrition and Overweight. Of 22 objectives, none were met, 2 moved toward the target, 3 demonstrated no change, and 15 moved away from the target. These findings are consistent with the epidemic of overweight and obesity in the United States and reflect the continuing influence of factors in our society that contribute to inactivity and weight gain (Fryar et al., 2014).

Healthy People 2020

Goals

For ***Healthy People 2020*** (USDHHS, Office of Disease Prevention and Health Promotion, 2011), there are four overarching goals:

- Attain high quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

These four goals established the territory in which health promotion and disease prevention efforts occur. Research in a variety of areas has clearly indicated that health disparities are directly and indirectly linked to longevity and quality-of-life issues (Barr, 2014). For example, the American Cancer Society reports that black men die of prostate cancer more frequently than any other racial or ethnic group, with their death rate almost 2.4 times higher than that of white men (American Cancer Society, 2016) (Box 1-2: Diversity Awareness).

Box 1-2

Diversity Awareness

Influence of Personal Cultural Values on Health Care Delivery

Culture influences every aspect of human life, including beliefs, values, and customs regarding lifestyle and health care. As health care providers, nurses need to be aware of their own beliefs, values, and customs and how these ideas translate into behavior. It is easy to

assume that an individual's own perspective is correct and shared by others. This is especially true when one is working with other health care providers who share the same culture. This concept is referred to as **ethnocentrism** and can lead to a devaluing of the beliefs, values, and customs of others, known as **racism.** Although it is impossible for any person to ignore the cultural influences on their lives, nurses and other health care providers have a special obligation to be aware of their own social and cultural biases. Our focus as nurses must be on the cultural influences in the daily lives of individuals through the development of **cultural competence** and cultural humility. The ability to view other people's situations from their perspective is known as **empathy.** Diversity awareness will continue to challenge providers to lifelong learning about the people for whom they provide care as the racial and ethnic mix in society changes.

The *Healthy People 2020* focus areas include adolescent health; blood disorders and blood safety; dementias, including Alzheimer disease; early and middle childhood; genomics; global health; health care–associated infections; health-related quality of life and well-being; lesbian, gay, bisexual, and transgender health; older adults; preparedness; sleep health; and social determinants of health. These focus areas are an expansion on previous areas and incorporate recent evidence more directly in each area.

The detailed objectives can be found at https://www.healthypeople.gov/2020/topics-objectives. These focus areas span age categories from conception to death and incorporate prevention, access, treatment, and follow-up at the individual, family, provider, work site, and community levels. The 42 topical areas lead to specific objectives for each topical area. One example is used here for illustration.

Objective PA-2.1. Increase the proportion of adults who engage in aerobic physical activity of at least moderate intensity for at least 150 minutes/week, or 75 minutes/week of vigorous intensity, or an equivalent combination. This objective directly addresses each of the overarching goals, either directly or indirectly. Physical activity can contribute to the

maintenance or improvement in mobility, which improves the quality of life and prevents disability. It is something in which most people can participate. It enhances positive mental health through stress reduction and physical fitness, which contribute to the development of healthy behaviors. However, it takes social action and awareness to address the need for social and physical environments that support physical activity across the life span.

Access to health care to obtain a complete physical examination before starting to exercise and the quality of the work or neighborhood environment available for exercise can contribute to success or failure of this objective. This objective is related to other objectives such as nutrition, obesity, and stroke prevention (Box 1-3: Innovative Practice).

Box 1-3

Innovative Practice

Process for Assessing, Evaluating, and Treating Overweight and Obesity in Adults

Overweight and obesity are major concerns in public health because they contribute to other health problems such as high cholesterol level, high blood pressure, diabetes mellitus, heart disease, functional limitations, and disability. As part of the National Heart, Lung, and Blood Institute's (2000) obesity education initiative, titled Aim for a Healthy Weight, nurses have an important role to play in health education related to obesity prevention and control. More complete information and guidelines updated in 2012 can be obtained from http://www.nhlbi.nih.gov/health/public/heart/obesity/lose_wt/index.ht

Make the Most of the Individual's Visit and Set an Effective Tone for Communication: Nurses ask individuals about their weight history, weight-related health risks, and desire to lose weight. The approaches used need to be respectful of a person's lifestyle, habits, and cultural influences. Discussions need to be nonjudgmental and

goal directed.

Assess the Individual's Motivation/Readiness to Lose Weight: Nurses explain body mass index and why it is the preferred method of determining overweight and obesity in adults. Individuals need to understand the methods of data collection and measurement of height and weight, as well as waist circumference, risk factors, and comorbidities. Nurses develop skill in determining readiness and motivation to lose weight in their patients.

Build a Partnership With an Individual: Nurses work with individuals to determine what each person is willing to do to achieve a lower weight. This approach includes knowing the best practices in weight management and weight loss. Fad diets, dietary supplements, and weight loss pills may be inappropriate for most people, and formal weight loss programs may be too expensive for low- and moderate-income families. Use recommended diets that restrict caloric intake, set activity goals with your patients, encourage the person to keep a weekly food and activity diary, and provide information on diet and activity. Be sure to record individual goals and the treatment plan, including a health-education plan. Nurses are knowledgeable about current treatment options and their success. Holistic approaches are needed because food behaviors are influenced by many factors. Listen to individuals' stories about food and its role in their lives. Therapies should fit the individual's goals and lead to lifestyle change.

Additionally, current knowledge of physical activity and specific populations was considered when the *Healthy People 2020* objectives were being created. Women, low-income populations, black and Hispanic people, people with disabilities, and those older than 75 years exercise less than do white men with moderate-to-high incomes (USDHHS, National Institutes of Health, National Heart, Lung, and Blood Institute, 2012). These health disparities can influence the number of people in these groups who develop high cholesterol levels or high blood pressure, which further increases their risk of heart disease and stroke. Although this objective addresses adults, other

objectives address the need for beginning exercise activities at an early age and encouraging young adults to be actively engaged in exercise. How might this objective be adjusted to the needs of an older adult population? The target for this objective is that 47.9% of adults engage in aerobic physical activity of at least moderate intensity for at least 150 minutes per week, or vigorous intensity for 75 minutes per week, or an equivalent combination. This target represents a 10% increase over the 2008 baseline. This approach emphasizes personal responsibility but now includes society's role in addressing the social and physical environments within which those choices are made (USDHHS, National Institutes of Health, National Heart, Lung, and Blood Institute, 2012).

The latest *Healthy People 2020* progress update on the goals of increasing access to health care services, addressing social determinants of health, and increasing the health-related quality of health for people indicates small improvements (Box 1-4).

Box 1-4

Healthy People 2020

The 13 Focus Areas

- Adolescent health
- Blood disorders and blood safety
- Dementias, including Alzheimer disease
- Early and middle childhood
- Genomics
- Global health
- Health care–associated infections

- Health-related quality of life and well-being
- Lesbian, gay, bisexual, and transgender health
- Older adults
- Preparedness
- Sleep health
- Social determinants of health

From US Department of Health and Human Services, Public Health Service. (2010). *Healthy People 2020.* https://www.healthypeople.gov.

The two leading health indicators for access to health care services of persons with medical insurance (<65 years old) and persons with a usual primary care provider showed little or no detectable change (USDHHS, 2014). The latest figure for the improvement in the rate of persons with medical insurance was 83.1% (2012), the baseline rate was 83% (2008), and the goal is 100%. In 2011, 77.3% of people had a usual primary care provider, the baseline rate was 76.3% (2007), and the goal is 83.9%. Social determinants of health are represented by the leading health indicator of students who graduate with a regular diploma 4 years after starting 9th grade. There has been an overall increase from 79% (2010–11) to 81%, although there are dramatic differences in graduation rates according to race and ethnicity. Improving the health-related quality of life and well-being of adults is considered by measurement of the proportion of adults who self-report good or better physical and mental health. Men report good or better physical health at a rate of 82.5%, with women trailing at a rate of 75.4%, and 81.1% of men report good or better mental health compared with 77.3% of women. Education is related to good or better health. The more educated one is, the higher the level of reported good or better health (USDHHS, 2014).

Health care providers need to be responsible for offering health promotion, providing preventive health services, and monitoring

behaviors. Unfortunately, many of the financial incentives for providers are to perform tasks and procedures rather than to counsel and help individuals choose between various behaviors. The Patient Protection and Affordable Care Act (US Congress, 2010) now requires primary care providers to provide free wellness services to older adults and others, and to provide person-centered care. Providers need to take the time to discuss behaviors that may improve the quality of life and extend the number of years of life. For example, the addictive nature of tobacco and its effect on the development and course of a variety of chronic health conditions are now well recognized. Providers should be asking every person if they use tobacco and should be providing them with ways to quit smoking, including economic and social incentives.

Providers also need to look for partnership in the community through which they can better serve the needs of individuals. *Healthy People 2020* emphasizes that person-centered care is essential to health promotion. One approach to person-centered care to build partnerships is the use of community nursing centers as partnering organization (http://www.nncc.us/site/). The Health Promotion Center operated by Fairfield University School of Nursing in Fairfield, Connecticut, was one example. The nurses and nursing students who provided health education, screening, and referral services at the Health Promotion Center worked with existing community organizations to better meet the health care needs of underserved people. The Health Promotion Center worked with senior housing and senior centers to provide comprehensive cardiovascular screenings and medication review. As an extension of this work, funding was secured for a program called Step Up to Health, a project to increase physical activity in this population through interactive planning and consumer ownership of the activities. The project was part of the National Blueprint Project supported by the Robert Wood Johnson Foundation (http://www.agingblueprint.org). The project engaged older adults in walking programs, line dancing, gardening, and low-impact exercise programs, including programs from the National Arthritis Foundation (http://www.arthritis.org/) (Box 1-5).

Box 1-5

Healthy People 2020

Selected National Health Promotion and Disease Prevention Objectives for Nutrition and Weight Status

- Increase the proportion of adults who are at a healthy weight.
- Reduce the proportion of adults who are obese.
- Reduce the proportion of children and adolescents who are considered obese.
- (Developmental) Prevent inappropriate weight gain in youth and adults.
- Increase the contribution of fruits to the diets of the population aged 2 years or older.
- Increase the variety and contribution of vegetables to the diets of the population aged 2 years or older.
- Increase the contribution of whole grains to the diets of the population aged 2 years or older.
- Reduce consumption of calories from solid fats and added sugars in the population aged 2 years or older.
- Reduce consumption of saturated fat in the population aged 2 years or older.
- Reduce consumption of sodium in the population aged 2 years or older.
- Increase consumption of calcium in the population aged 2 years or

older.

From US Department of Health and Human Services, Public Health Service. (2010). *Healthy People 2020* objectives. https://www.healthypeople.gov.

Another approach to partnerships is to have providers serve as active participants on community boards and advisory committees, which allows providers to become aware of the service needs in the community and the resources available to meet those needs.

Work sites and communities need to become partners in providing opportunities for people to lead healthy lives through flexible work schedules, work site wellness programs, accessibility of safe parks, and availability of exercise facilities. Converting empty lots into community gardens provides beautification of the area, an opportunity for exercise in caring for the garden, and a source of fresh vegetables. The availability of bike paths encourages physical activity.

Churches, temples, and mosques can be vital partners in meeting *Healthy People 2020* objectives. Faith communities can break economic, social, racial, and gender barriers, making them an excellent source for sharing information on health promotion and disease prevention. Parish nurses are becoming increasingly prevalent, and they incorporate *Healthy People 2020* objectives into their activities (International Parish Nurse Resource Center, 2012).

Public health officials at all levels are necessary partners in meeting *Healthy People 2020* objectives. As part of the core public health functions of assessment, policy development, and assurance, the US Public Health Service and all state, county, and local health departments need to collect data, make information available to the public, create policies that support *Healthy People 2020* objectives, and ensure that needed services are available from a competent workforce.

Healthy People 2020 can form the basis for planning, service delivery, evaluation, and research in every aspect of the health care system. The nurse needs to be familiar with this document and its intent. Nurses should compare their practices with the objectives of *Healthy People 2020*. Additionally, the nurse needs to be aware of the research and practice changes that occur as a result of the work toward these

objectives.

Levels of Prevention

Prevention, in a narrow sense, means averting the development of disease. In a broad sense, prevention consists of all measures that limit disease progression. Leavell and Clark (1965) defined three **levels of prevention:** primary, secondary, and tertiary (Figure 1-2). Although the levels of prevention are related to the natural history of disease, they can be used to prevent disease and provide nurses with starting points for making effective, positive changes in the health status of the persons for whom they provide care. Primordial prevention, the earliest form of prevention, has been added as a type of prevention that reflects policy-level intervention aimed at affecting health before at-risk lifestyle behaviors are chosen or become habit. Within the four levels of prevention, there are five steps. These steps include health promotion and specific protection (primordial and primary prevention); early diagnosis, prompt treatment, and disability limitation (secondary prevention); and restoration and rehabilitation (tertiary prevention).

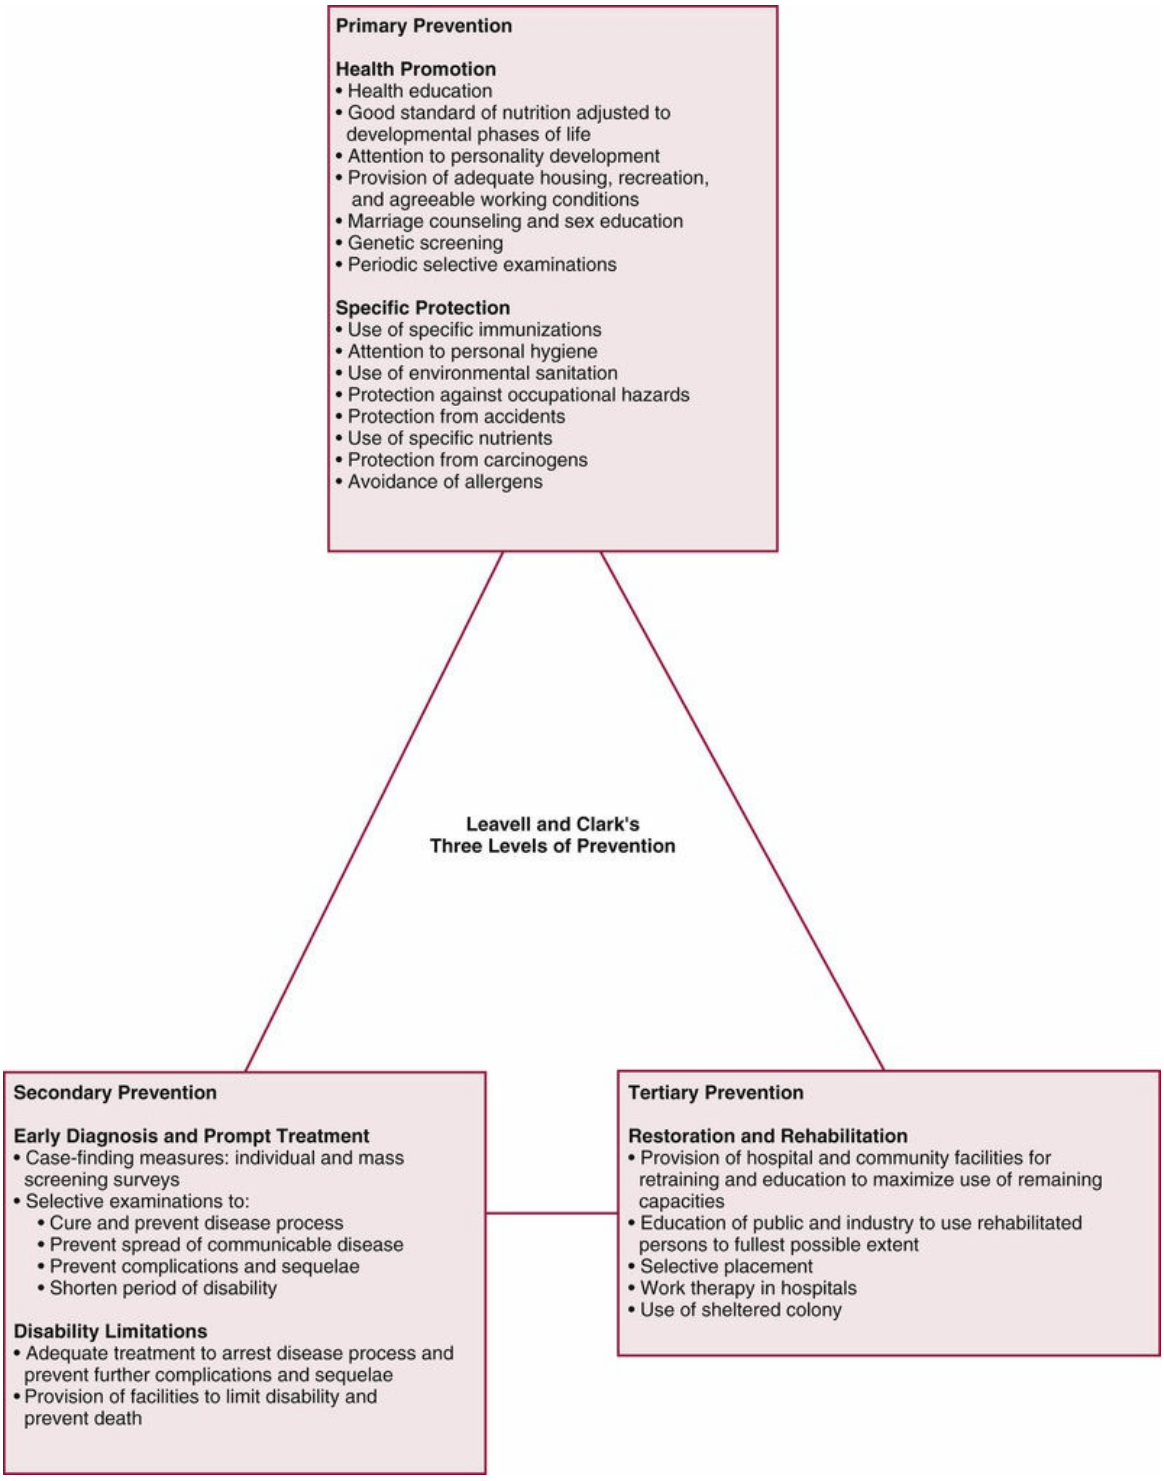

FIGURE 1-2 The three levels of prevention developed by Leavell and Clark. (Modified from Leavell, H., & Clark, A. E. (1965). *Preventive medicine for doctors in the community*. New York: McGraw-Hill; Ali, A., & Katz, D.L. (2015). Disease prevention and health promotion: How

integrative medicine fits. *American Journal of Preventive Medicine, 49*(5), S230–S240.)

Some confusion exists in the interpretation of these concepts; therefore a consistent understanding of primordial, primary, secondary, and tertiary prevention is essential. The levels of prevention operate on a continuum but may overlap in practice. The nurse must clearly understand the goals of each level to intervene effectively in keeping people healthy.

Primordial Prevention

"Primordial" refers to the timeframe *before* a risk factor develops and *before* disease occurs. Primordial prevention can begin as early as childhood or even prenatally and is closely linked to the determinants of health and the environment in which one lives (Salama, n.d.). Determinants of health include income, education, literacy, employment, working conditions, social and physical environment, health practices, genetic makeup, health services, gender, and culture (Association of Faculties of Medicine of Canada, n.d.). Primordial interventions are aimed at determinants of health. For example, if the social environment one grows up in discourages exercise or encourages eating high-fat food, that environment could be targeted for primordial prevention. Healthy eating and activity school-based programs, reduction of sodium in the food supply, and creation of safe places to ride bikes and walk are examples of primordial prevention (Weintraub et al., 2011). Most health-promoting primordial prevention occurs at the national, state, and community levels.

Primary Prevention

Primary prevention precedes disease or dysfunction. However, primary prevention is therapeutic in that it includes health as beneficial to well-being, it uses therapeutic treatments, and, as a process or behavior toward enhancing health, it involves symptom identification when stress reduction techniques are being taught. Primary prevention intervention includes health promotion, such as

health education about risk factors for heart disease, and **specific protection,** such as immunization against hepatitis B. Its purpose is to decrease the vulnerability of the individual or population to disease or dysfunction. Interventions at this level encourage individuals and groups to become more aware of the means of improving health and the actions they can take at the primary preventive health level and the optimal health level. People are also taught to use appropriate primary preventive measures. However, primary prevention can also include advocating policies that promote the health of the community and electing public officials who will enact legislation that protects the health of the public.

Health Protection

Primordial and primary prevention activities focus on the reduction of threats and negative influences on health. Both types of prevention can occur at an individual level and at the community, state, national, and even global levels. Ensuring safe and adequate food, water, and medical therapies for all people as well as protecting them against workplace and environmental hazards is a regional and global objective. Ruger et al. (2015) suggest the formation of a global health fund that would unite efforts to ensure adequate protection of all the world's people concerning AIDS, tuberculosis, and malaria in recognition of the global responsibility for social protection.

Health Promotion

The definitions of **health promotion** differ. O'Donnell (1987) has defined health promotion as "the science and art of helping people change their lifestyle to move toward a state of optimal health." Kreuter and Devore (1980) proposed a more complex definition in an article commissioned by the US Public Health Service. They stated that health promotion is "the process of advocating health to enhance the probability that personal (individual, family, and community), private (professional and business), and public (federal, state, and local government) support of positive health practices will become a

societal norm."

The theoretical basis of health promotion.

The theoretical underpinnings for health promotion have evolved since the early 1980s. Most of these theories are behaviorally based, derived from the social sciences, and extensively researched. These theories include the theory of reasoned action by Ajzen and Fishbein (1980), theories of behavior by Bandura (1976, 1999, 2004), the health belief model by Rosenstock (Champion & Skinner, 2008), Pender's health-promotion model (Pender et al., 2015), and stages of change theories by Prochaska (Prochaska et al., 2004). Internet searches on each of these theories will provide numerous websites where more detailed information is available.

The social nature of health promotion.

Health promotion goes beyond providing information. It is also proactive decision-making at all levels of society as reflected in the *Healthy People 2020* objectives. Health promotion holds the best promise for lower-cost methods of limiting the constant increase in health care costs and for empowering people to be responsible for the aspects of their lives that can enhance well-being. Based on the need for health-promotion activities within the health care system, efforts must be made to identify the multiple determinants of health, determine relevant health-promotion strategies, and delineate issues relevant to social justice and access to care. Individuals, families, and communities must be active participants in this process so that the actions taken are socially relevant, economically feasible, and supportive of changes at the individual level.

The active and passive nature of health promotion.

Health-promotion efforts, unlike those efforts directed at specific protection from certain diseases, focus on maintaining or improving the general health of individuals, families, and communities. These activities are conducted at the public level (e.g., government programs promoting adequate housing or reducing pollutants in the air), at the

community level (e.g., Habitat for Humanity or community health centers), and at the personal level (e.g., voting to offer low-income housing or to elect public officials who recognize the need for public oversight). Nursing interventions are actions directed toward developing people's resources to maintain or enhance their well-being —a form of assets-based planning.

Strategies of health promotion that involve the individual may be either passive or active. Passive strategies involve the individual as an inactive participant or recipient. Examples of passive strategies include public health efforts to maintain clean water and sanitary sewage systems to decrease infectious diseases and improve health, and efforts to introduce vitamin D in all milk to ensure that children will not be at high risk of rickets when living in areas where sunlight is scarce. These passive strategies must be used to promote the health of the public when individual participation might be low but the benefit to society is high.

Active strategies depend on the individual becoming personally involved in adopting a proposed program of health promotion. Two examples of lifestyle change are performing daily exercise as part of a physical fitness plan and adopting a stress-management program as part of daily living. A combination of active and passive strategies is best for making an individual or society healthier. This text is concerned almost entirely with active strategies and the nurse's role in these strategies. Some passive strategies are presented but they are presented with the implicit belief that each individual must take responsibility for improving health. It is undeniable that passive strategies also have a valuable role, but they must be used within a context of encouraging and teaching individuals to assume more responsibility for their health.

An application of theory to the practice of health promotion.

The transtheoretical model (TTM) is an excellent example and can be applied to this case study. TTM incorporates stages of change (readiness to take action), decisional balance (benefits to and detractors from changing a behavior), self-efficacy (personal

confidence in making a change), and processes of change (cognitive, affective, and behavioral activities facilitating change). The bases of TTM are the stages of change; six stages that people spiral through on a path toward making and sustaining a behavioral change to promote health. These stages are:

Precontemplative	Not considering change
Contemplative	Aware of but not considering change soon
Preparation	Planning to act soon
Action	Has begun to make behavioral change (recent)
Maintenance	Continued commitment to behavior (long-term)
Relapse	Reverted to old behavior

Each stage offers opportunities for the nurse to provide information and support behavioral change. Encouraging people and suggesting changes to their environment that support behavioral change can increase individuals' self-efficacy and their chances of maintaining a change. This model also recognizes that people need multiple opportunities to make behavioral change before achieving success and that relapse should be expected (Prochaska et al., 2004).

Although health promotion would seem to be a practical and effective mode of health care, the major portion of health care delivery is geared toward responding to acute and chronic disease. Preventing or delaying the onset of chronic disease and adding new dimensions to the quality of life are not as easy because they take time to implement and evaluate and require personal action. These actions are more closely associated with everyday living and the lifestyles adopted by individuals, families, communities, and nations. Habits such as eating, resting, exercising, and handling anxieties appear to be transmitted from parent to child and from social group to social group as part of a cultural, not a genetic, heritage. These activities may be taught in subtle ways but they influence behavior and have as much of an influence on health as does genetic inheritance. Although the public may not appreciate the causal relationships between behavior and health, they should be apparent to health professionals. Arguably, the concept of risk is the most basic of all health concepts, because health promotion and disease protection are based on this concept.

Health-promotion strategies have the potential of enhancing the

quality of life from birth to death. For example, good nutrition is adjusted to various developmental phases in life to account for rapid growth and development in infancy and early childhood, physiological changes associated with adolescence, extra demands during pregnancy, and the many changes occurring in older adults. Good nutrition is known to enhance the immune system, enabling individuals to fight infections that could lead to disabling illnesses. Other individual activities are adapted to the person's needs for optimal personality development at all ages. As seen in Unit 4, much can be done on a personal or group basis, through counseling and properly directed parent education, to provide the environmental requirements for the proper personality development of children. Community participation is also an important factor in promoting individual, family, and group health (see Chapters 6–8).

Personal health promotion is usually provided through health education (see Chapter 10). An important function of nurses, physicians, and allied health professionals, health education is principally concerned with eliciting useful changes in human behavior on the basis of current research. The goal is to inculcate a sense of responsibility in individuals for their own health and a shared sense of responsibility for avoiding injury to the health of others. For example, encouraging child-rearing practices that foster normal growth and development (personal, social, and physical) addresses both the individual parent and the needs of society. Health education nurtures health-promoting habits, values, and attitudes that must be learned through practice. These must be reinforced through systematic instruction in hygiene, bodily function, physical fitness, and use of leisure time. Another goal is to understand the appropriate use of health services. For example, a semiannual visit to a dentist may teach a child better oral health habits and to visit the dentist regularly, although this is not the primary purpose of the visit. Parents, teachers, and caregivers play a vital role in health education. In addition to teaching individuals, nurses need to develop skills in group teaching and in providing education within community organizations.

Available research clearly shows an increase in longevity, a decrease in mortality and morbidity, and an improvement in the quality of life for individuals who have been involved in health-promotion activities such as physical activity and avoidance of smoking (Crimmins et al., 2011). It must be emphasized that health promotion requires lifestyle change. Once a lifestyle change has been adopted, vigilance is needed to ensure that the lifestyle change is maintained and modified to fit developmental and environmental changes.

Empirical data linking risk factors, health-promotion activities, and outcomes are sufficient to drive the development of the *Healthy People 2020* objectives and to be incorporated into quality improvement measures in managed care. One of the challenges posed in *Healthy People 2020* is the development of measurable outcome objectives that are based on more realistic economic models.

Health promotion is an important concept for nursing because it embodies many other concepts that nursing is concerned with today. As stated earlier, much of the nursing role is involved with health teaching. Standard 5B of *Nursing: Scope and Standards of Practice* (American Nurses Association [ANA], 2015b) includes a full section on the practice implementation of health teaching and health promotion. Nurses are expected to demonstrate professional role competence throughout their careers. Health education is clearly an important nursing role.

Specific Protection

This aspect of primary prevention focuses on protecting people from injury and disease, for example, by providing immunizations and reducing exposure to occupational hazards, carcinogens, and other environmental health risks. These hazards and risks include not only protection of adults from work-related injuries (e.g., back injuries in nurses, dismemberment in machinists, exposure to chemicals used in boat repair or exposure to inhaled sawdust by carpenters) but also protection of infants and children from potential carcinogens (e.g., exposure of children to diesel emissions, damage to a fetus caused by

radiation).

Primary prevention interventions are considered health protection when they emphasize shielding or defending the body (or the public) from specific causes of injury or disease. Implementing nursing interventions that prevent a specific health problem may seem easier than promoting well-being among individuals, groups, or communities because the variables are delineated more clearly in prevention than in promotion and the potential influences are less diverse.

Examples.

Two examples may help demonstrate these differences. Immunization against influenza is quite popular and has become a regular activity for people at risk each fall. Nurses can participate in this specific protection role by giving the influenza injections in clinics and offices. Another example is the creation of nut-free schools to protect hypersensitive children from life-threatening allergic reactions to peanuts and nut products. Such initiatives have largely been the result of grassroots parent organizations working with formal community organizations to adopt policies that protect the health of these children. Nurses may be involved in the parent organizations or the school or public health boards that review the proposed policies. Additionally, nurses must be able to address the need to protect specific portions of the population at risk.

Secondary Prevention

Although primary prevention measures have decreased the hazards of chronic diseases such as cardiovascular disease, conditions that preclude a healthy quality of life are still prevalent. Secondary prevention ranges from providing screening activities and treating early stages of disease to limiting disability by averting or delaying the consequences of advanced disease.

Screening is secondary prevention because the principal goal is to identify individuals in an early, detectable stage of the disease process. However, screening provides an excellent opportunity to

offer health teaching as a primary preventive measure. Screening activities now play an important role in the control of diseases such as heart disease, stroke, and colorectal cancer. Additionally, screening activities provide early diagnosis and treatment of nutritional, behavioral, and other related problems. Nurses play an important role in screening activities because they provide clinical expertise and educationally sound health information during the screening process.

Delayed recognition of disease results in the need to limit future disability in late secondary prevention. Limiting disability is a vital role for nursing because preventive measures are primarily therapeutic and are aimed at arresting the disease and preventing further complications. The paradox here is that health education and disease prevention activities seem similar to those used in primary prevention, but are applied to a person or population with an existing disease. Modifications to the teaching plan must be made on the basis of the individual's current health status and ability to modify behavior.

Tertiary Prevention

Tertiary prevention occurs when a defect or disability is permanent and irreversible. The process involves minimizing the effects of disease and disability by surveillance and maintenance activities aimed at preventing complications and deterioration. Tertiary prevention focuses on rehabilitation to help people attain and retain an optimal level of functioning regardless of their disabling condition. The objective is to return the affected individual to a useful place in society, maximize remaining capacities, or both. The responsibility of the nurse is to ensure that persons with disabilities receive services that enable them to live and work according to the resources that are still available to them. When a person has a stroke, rehabilitating this individual to the highest level of functioning and teaching lifestyle changes to prevent future strokes are examples of tertiary prevention.

The Nurse's Role

Evolving demands are placed on the nurse and the nursing profession as a result of changes in society. Emphasis is shifting from acute, hospital-based care to preventive, **community-based care,** which is provided in nontraditional health care settings in the community. This demand for community-based services, with the home as a major community setting for care, is closely related to the changing demographics of the United States. While the home and community become the existing sites for care, nurses must assume more blended roles, with a knowledge base that prepares them to practice across settings using **evidence-based practice.** Within these roles, nurses assume a more active involvement in the prevention of disease and the promotion of health. Nurses can be more independent in their practice and place a greater emphasis on promoting and maximizing health, and more than ever nurses are accountable morally, ethically, and legally for their professional behavior.

Nursing Roles in Health Promotion and Protection

Although nurses often work with people on a one-to-one basis, they seldom work in isolation. Within today's health care system, nurses collaborate with other nurses, physicians, social workers, nutritionists, psychologists, therapists, individuals, and community groups. In this **interprofessional practice,** nurses play a variety of roles.

Advocate

As advocates nurses help individuals obtain what they are entitled to receive through the health care system, try to make the system more responsive to individual and community needs, and help people develop the skills to advocate for themselves. In the role of an advocate, the nurse strives to ensure that all persons receive high-quality, appropriate, safe, and cost-effective care. The nurse may spend a great deal of time identifying and coordinating resources for

complex cases.

Care Manager

The nurse acts as a care manager to prevent duplication of services, maintain quality and safety, and reduce costs. Information gathered from reliable data sources enables the care manager to help individuals avoid care that is unproven, ineffective, or unsafe. Reliable sources of information on best practices, evidence-based practices, and standard protocols are available from Internet sites sponsored by the federal government (e.g., https://www.nih.gov; https://www.cdc.gov), specialty organizations (e.g., http://www.arthritis.org; http://www.nursingworld.org; http://www.aginglifecare.org), and private foundations (e.g., http://www.rwjf.org; http://www.johnahartford.org). Successful care management depends on a collaborative relationship among the care manager, other nurses and physicians, the individual and his or her family, the insurance provider, and other care providers who work with the person. The wishes of the individual and the family need to be clear to the care manager as part of person-centered care provision. Facilitating communication among parties is one of the care manager's most important functions.

Consultant

Nurses may provide knowledge about health promotion and disease prevention to individuals and groups as a consultant. Some nurses have specialized areas of expertise or advanced practice, such as in gerontology, women's health, or community/public health, and they are equipped to provide information as consultants in these areas of specialization (ANA, 2015b). A gerontological nurse specialist might be on a community planning board offering advice about what types of health-promotion activities should be considered in planning a new senior housing development. All nurses need to develop consultation skills that can be integrated into practice and allow the individual nurse to take advantage of opportunities to provide support on an

individual level or for future development at the organizational level (Norwood, 2003).

Deliverer of Services

The core role of the nurse is the delivery of direct services such as health education, influenza vaccinations, and counseling in health promotion. Visible, direct delivery of nursing care is the foundation for the public image of nursing. The public demands that nurses be knowledgeable and competent in their delivery of services. This role is clearly expressed in *Nursing's Social Policy Statement* (ANA, 2010) and in the *Code of Ethics for Nurses with Interpretive Statements* (ANA, 2015a).

Educator

Health practices in the United States are derived from the theory that health components such as good nutrition, industrial and highway safety, immunization, and specific drug therapy should be within the grasp of the total population. Even with its rich resources, society falls far short of attaining the goal of maximal health for all. The problem is not a lack of knowledge, but rather the lack of application; therefore it is incumbent on nurses to be excellent health educators. To teach effectively, the nurse must know essential facts about how people learn and the teaching-learning process (see Chapter 10).

In addition to their storehouse of scientific knowledge, nurses who are committed to their teaching role know that individuals are unique in their response to efforts to change their behavior. Teaching may range from a chance remark by the nurse, based on a perception of desirable individual behavior, to structurally planned teaching according to individual needs. Selection of the methods most likely to succeed involves the establishment of teacher-learner goals. Health promotion and protection rely heavily on the individual's ability to use appropriate knowledge. Health education is one of the primary prevention techniques available to avoid the major causes of disability and death today and is a critical role for nurses.

Healer

The role of healer requires the nurse to help individuals integrate and balance the various parts of their lives (McKivergin, 2009). Healing resides in the ability to glimpse or intuit the "interior" of an individual, to sense and identify what is important to that other person, and to incorporate the specific insight into a care plan that helps that person develop his or her own capacity to heal. It requires a mindful blending of science and subjectivity (Benner et al., 2010; Siegel, 2007). Nurses have a special ability to help people heal. The art of nursing is the extraordinary ability to manage a broad array of information to create something meaningful, sensible, and whole (see Chapter 14).

Researcher

In today's health care environment, nurses are constantly striving to understand and interpret research findings that will enhance the quality and value of individual care. To provide optimal health care, nurses need to use evidence-based findings as their foundation for clinical decision-making. When nurses or other clinicians use research findings and the best evidence possible to make decisions, the outcome is termed **evidence-based practice.** Evidence-based practice is defined as the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individuals. The practice of evidence-based nursing means integrating individual clinical expertise with the best available external clinical evidence from systematic research (ANA, 2015b).

The National Institute of Nursing Research (NINR) serves as the focal point in developing research themes for the future of the profession. NINR supports research to establish a scientific base for the care of individuals throughout the life span; from the management of individuals during illness and recovery to the reduction of the risks of disease and disability. The five "investment" themes NINR has identified are to enhance health promotion and disease prevention; to improve quality of life through symptom management; to improve

palliative and end-of-life care; to enhance innovation in science and nurse practice; and to encourage a new generation of nurse scientists (NINR, 2011). Notice how the *Healthy People 2020* objectives match many of these themes.

Evidence-based practice involves searching for the best evidence with which to answer clinical research questions. Research evidence can be gathered from **quantitative studies** that describe situations, correlate different variables related to care, or test causal relationships between variables related to care (levels I to IV). Such studies become incorporated into screening and treatment standards such as those from the US Preventive Services Task Force (2014). Research evidence can also be gathered from **qualitative studies** that describe phenomena or define the historical nature, cultural relevance, or philosophical basis of aspects of nursing care (levels V to VII). **Applied research** is done to directly affect clinical practice (Burns & Grove, 2014). Sackett and colleagues (1996) stressed the use of the best evidence available to answer clinical questions and explore the next best evidence when appropriate. The next best evidence may include the individual clinical judgment that nurses acquire through clinical experience and clinical practice and other qualitative approaches to research.

Nurses need to recognize that research is important as a basis for their practice and that they need to participate in the research process. For example, both home health nurses and nurses in long-term care facilities are required to collect extensive data on the cognitive and physical functioning of individuals through the Outcome and Assessment Information Set (OASIS) and Minimum Data Set (MDS) assessment tools. These data are used as part of the quality improvement process to indicate areas for improvement in care, thereby contributing to nursing protocols. Nurses in hospital settings are asked to participate in research as part of the Magnet Hospital designation process.

Chapters 16 to 24 contain specific health-promotion research studies. Time should be taken to review these studies and explore the relationship between behavior and disease, to identify which

population groups are at risk, and to discover what types of health-promotion programs work and why they work. Through knowledge of research, nurses can strengthen their confidence in making daily decisions about quality care (Box 1-6: Research for Evidence-Based Practice).

Box 1-6

Research for Evidence-Based Practice

Preventing Functional Decline in Hospitalized Older Adults

The ability to function independently is important throughout life, but especially as one ages. Although some loss of independence in physical functioning may be expected over time, hospitalization should not contribute to physical function loss. Current practice in most hospitals is to limit a person's mobility and independence in activities of daily living. At times these limitations are imposed to prevent falls or other events for the benefit of the individual. But at other times limitations are imposed for the convenience of the staff or to decrease the risk of liability.

Older adults are at risk of losing their functional abilities if the hospitalization-imposed limitations interfere with their normal level of activity. A prolonged hospitalization and rehabilitation period can lead to deconditioning, where the person loses muscle mass, strength, and range of motion as a result of a decrease in his or her activity. Research has demonstrated that such declines can further limit the activities of daily living for these older adults (Graf, 2006).

Evidence is now available to improve the quality of hospital and long-term care of older adults. Actions include establishing functional baseline data through geriatric assessments at the time of admission and at other set times during the stay; using protocols to improve self-care, nutrition, sleep quality, and cognition; minimizing the adverse events that may further influence loss of physical function;

and improving the hospital environment to better serve an older adult population (Kleinpell et al., 2008). It is still the nurse caring for the individual person who is most likely to see the need for applying this evidence to improve the care of the hospitalized older adult.

From Graf, C. (2006). Functional decline in hospitalized older adults. *American Journal of Nursing*, *106*, 58–67; Kleinpell, R., Fletcher, K., & Jennings, B. (2008). Reducing functional decline in hospitalized elderly. In R.G. Hughes (Ed.), *Patient safety and quality: An evidence-based handbook for nurses.* Rockville, MD: Agency for Healthcare Research and Quality. http://www.ncbi.nlm.nih.gov/books/NBK2629/?report=printable.

Improving Prospects for Health

Population Effects

Cultural and socioeconomic changes within the population unequivocally influence lay concepts of health and health promotion. Currently there are areas of the United States where the Hispanic population is larger than any other population group. By the 2050, it is predicted that the majority of people in the United States will not be of white European descent (US Census Bureau, 2010a). Taken together as a portent for future health-promotion strategies, these predictions about the population indicate that current knowledge of and approaches to health promotion may not meet the needs of the future US population (see Chapter 2).

In addition to changes in the ethnic and racial distribution within the population, the projected changes in age distribution will affect health-promotion practice. Considerable growth is expected in the proportion of the population that is aged 25 years or older. For example, the post–World War II baby boom will increase the number of people in the 65 years and older age group between 2010 and 2030 (US Census Bureau, 2010b). Although there was a drop in births after 1960, this decrease has been offset by an increase in immigration, both legal and illegal. More restrictive immigration rules related to homeland security have limited legal immigration since 2002 (US Department of Homeland Security, 2016). Analysis of these population trends and projections helps health professionals determine changing needs. Additionally, analysis of the social and economic environment is necessary for the development of social policy concerning health.

Shifting Problems

The provision of personal health services must be influenced by current information regarding environmental health. Environmental pollution is a complex and increasingly hazardous problem. Diseases related to industry and technology, including asthma and trauma, have become important threats to health.

The physical and psychological stresses of a rapidly changing and fast-paced society present daily problems, such as psychosocial and spiritual poor health habits. Posttraumatic stress disorder is becoming a more common diagnosis. Obesity, partly attributed to a lack of exercise and increasing food portion size, is a growing health issue. The ingestion of potentially toxic, nonnutritious, high-fat foods is another contributing factor (see Chapter 11). The abuse of tobacco, drugs, and alcohol also negatively affects health.

The emphasis on treating disease through the application of complex technology not only is costly but also contributes minimally to the improvement of health. An orientation toward illness clearly focuses on the effects rather than the causes of disease.

A substantial change in wellness patterns is occurring. Infectious and acute diseases were the major causes of death in the early part of the 20th century, whereas chronic conditions, heart disease, cerebrovascular accident (stroke), and cancer are the major causes today. An emphasis on the diagnosis and treatment of disease, which were highly successful in the past, is not the answer for today's needs, which are closely related to and affected by the individual's biochemical functioning, genetics, environment, and personal choices (Box 1-7). The Patient Protection and Affordable Care Act (US Congress, 2010) was enacted to begin the process of paying for health promotion by providing insurance coverage for more people and by covering preventive health services.

Box 1-7

Genomics

Genetic research is primarily concerned with discovering, detecting, and treating illnesses related to specific abnormal genetic sequences (Khoury, 2011). Genomics, as a research focus, involves the study of all human genes, which are collectively called the human genome. The study and practice of genomics is concerned with how genes express themselves and how they interact with each other and the environment to encourage or discourage disease (Allen et al., 2014). Genomic interests range from an individual level to a population-based level similar to health-promoting activities. Genomics at an individual level is concerned with an individual's risks related to that person's genomic profile and environmental stimuli. At the population level, genomics is concerned with large-scale patterns of genomic risk and how that plays out in the public arena. Therefore population-based public health genomics is involved with policy development, prioritizing useful genomic information, and ensuring that genomic information is discovered and used ethically and responsibly (Khoury, 2011).

Lifestyle, environment, and genetics and the interaction between the three are determining factors of disease. Currently the focus of much intervention is on the lifestyle and environmental contributors to disease. Because we are just beginning to look at the genomic components of disease and how they interact with lifestyle and environment, the current scientific discussion revolves around the ethical implications of private and public genomic interventions. Current debate surrounding population genomics focuses on the public's “right not to know” (Allen et al., 2014). Genomic information can be used to formulate public health information and initiatives. There are potential social justice ramifications in sharing large-scale genomic information which may accentuate discrimination and worsen stigma. If the information is too complex or difficult to comprehend, it may demotivate people from making needed positive changes. For example, if there is a health behavior that is linked to a particular genomic profile, knowing that could help those who do not have the genomic profile become motivated to change their behavior,

whereas people with the genetic profile might become demotivated to change their behavior. Because it is a combination of factors that cause disease, just because a person has the genetic profile does not mean it is an absolute that the person will get the disease, so sharing this information incautiously may be a disservice to public health as opposed to a service. Careful consideration of the risks and benefits of sharing public genomic-related information is essential.

From Allen, C., Senecal, K., & Avard, D. (2014). Defining the scope of public engagement: Examining the "right not to know" in public health genomics. *Public Health Genomics, 42*(1), 11-18; Khoury, M. J. (2011). Public health genomics: The end of the beginning. *Genetics in Medicine, 13*(3), 206-209.

Moving Toward Solutions

Solutions are neither simple nor easy, but they can be focused in two major directions: individual involvement and government involvement. The first direction concentrates on actions of the individual, especially actions related to lifestyle choices across the life span. The learning and the inherent changes that are involved require the adoption of a new set of skills by people who will need the assistance of nurses to make those changes. Approximately one-fifth of the population of the United States is faced with the problem of getting the basic necessities of food and shelter. The other four-fifths, whose basic needs are met, must overcome problems resulting from affluence (USDHHS, Office of Disease Prevention and Health Promotion, 2011).

Motivational factors play a large role in influencing attitudinal change. As discussed in Chapter 10, programs for health promotion and health education are only part of the answer. Financial incentives for prevention may be another motivating factor, and health advocacy by professionals in the health field is critical. Additionally, private and public action at all levels is needed to reduce social and environmental health hazards. Toxic agents in the environment such as particles from diesel emissions and social conditions such as school overcrowding can present health hazards that may not be detected for years; therefore it is necessary for individuals and the government to play a role.

Legislation and financing that relate to primary prevention are discussed in Chapter 3. Government activity, in the form of legislation, is currently increasing in this area. For example, increasing the activity time in schools, mandating seat belt use, and implementing taxes on gasoline use are specific areas for governmental intervention. Health ecology and planning are important areas for government involvement in the future. The redirection of the existing health care delivery system, putting more emphasis on primary prevention, is probably the most difficult and

the most far-reaching goal; however, an emphasis on a wellness system is necessary to improve the health of the US population.

Case Study

Health Assessment: Frank Thompson and Family

Frank Thompson's large brick home is located off a sparsely traveled country road. A few yards away stands the uninhabited shack where Frank was born during World War II.

Frank was raised knowing the odds that he faced as a poor tenant farmer. He helped his father, Ben, with their small tobacco and corn crops. They were unaware that the hazardous chemicals in the pesticides they used would later affect Ben's life. As his father often reminded him, Frank had to do better than others in school so he would not be doomed to the tenant farmer's life. However, Frank's school attendance was erratic because it was interrupted by the frequent demand of tending field crops. Thin and often tired, Frank had recurrent infections. The school nurse helped the Thompson family obtain the necessary medication for Frank's initial infection, but the family was never able to afford the penicillin that was necessary to prevent recurrent infections.

Inspired by the early work of Martin Luther King, Jr., Frank was intent on helping at home and building something better for his future. Frank managed to more than compensate for his lost time at school. He passed his college entrance examinations and was awarded one of the new equal opportunity grants, which offered him a choice of attending any of the Ivy League schools in the Northeast. Instead, he chose the prestigious Southern University and eventually earned a master of business administration degree. He married Sada, his longtime girlfriend, and the two planned their future.

With a good job in a large local sales firm, Frank built his house and started a family. He moved from being a salesman to being a division head and often traveled to regional meetings, sometimes accompanied by Sada and their three children. Frank's dream of

sharing his success with his family included using part of his earnings to help his brothers and sisters with their education.

This new way of life meant Frank had little time for relaxation and frequently had to attend business luncheons and career-promoting social events. Frank kept late hours and worked long weekends. Good food, drinks, and cigarettes helped Frank relax before and after important business and social encounters; these softened the edges of hard bargaining and were status symbols.

Not surprisingly, Frank gained weight. He had a persistent cough, which was probably a result of the smoking habit that developed during the early years of his career. Frank's physician, whom Frank visited regularly at the corporation's health maintenance organization, said Frank's blood pressure and serum lipid levels were both higher than normal and that he had chronic bronchitis. The physician urged Frank to take the actions that Frank already recognized: reduce smoking, drinking, and intake of saturated fats and calories; get more exercise; and find ways to relax. However, Frank's life was too busy for exercise. He had to work harder because he was promoted in his company, but he also had to appear relaxed, which was an essential characteristic for a prospective vice president. To meet these goals, Frank tended to drink and smoke more. He also refused to take medication for problems he could not see. Without the outward signs of disease, Frank believed he was out of shape but generally healthy. Then Sada noted that his chance for promotion might actually improve if he lost some weight; therefore Frank registered for a physical fitness program for executives that he could attend on Sunday mornings and before work during the week. At his first workout, the classic sharp pain gripped his chest and Frank had a massive heart attack.

Weeks later, Frank was convalescing at home after being released from the university's coronary care facility. He was lucky to survive the heart attack and he was also fortunate to have most of the health care services covered by his medical insurance plan; in addition, 80% of his earnings were protected by the company's disability pension. (Most people in the United States do not have this protection.)

However, Frank's dreams of promotion were shattered. For many months he could go to the office only two or three times a week at most, simply to deal with routine matters. He could not travel, for business or otherwise, for a long time. He was also skeptical about his cardiac rehabilitation program because his heart attack happened during exercise.

Reflective Questions:

- As a nurse, how would you explain to Frank that his heart attack was not caused by his exercise?
- How might a family approach to diet and exercise work with this family, given its structure and background?
- Are there negative behaviors in your life that you see as status symbols?

Tying It All Together Using the Nursing Process

Problem Identification

How many problems are present in Frank's situation? The answer depends on who is asked the question and his or her position in relation to Frank. Each point of view focuses on different aspects of Frank's life. His physician, using a clinical model of health, might say that Frank has coronary heart disease with an acute myocardial infarction, hypertension, hyperlipidemia, chronic bronchitis, and obesity. But Frank's problems also represent a failure to meet several of the *Healthy People 2020* objectives on a personal level. His nurse can add that he has paid little attention to his lifestyle, even after changes were recommended. He continues to overeat, drink too much, smoke, not exercise, and live a stressful life. Frank's employer sees a man who has potential but who is now too disabled to take on new responsibilities and perhaps unable to continue performing his previous duties. Frank's children might feel that he can no longer take them on trips or play with them. His wife, Sada, knows that their plans for educating their children, and for travel and enjoyment, might suffer. The human resource personnel who manage Frank's health insurance and pension programs would say that he has an expensive disease, and the state health planner would point out that Frank's problem is only one of a growing number of disabling illnesses that result from preventable causes. A reviewer for *Healthy People 2020* might see Frank as part of the aggregated data on heart disease, indicating a continuing increase in the incidence of heart disease among black non-Hispanic men.

To Frank, his health problems are multidimensional. His initial fear of dying, pain, dependence, and frustration decreased as he began to feel better, but Frank is haunted by his realization that he might never be able to achieve his dreams for himself and his family. Although theoretically in his prime, Frank suddenly sees himself as far older

than his years, both in body and in social achievement. He believes he has reached his limit and that he will never again have the freedom to choose his future. He and his family needed to evaluate their situation and make alternative plans based on asset planning. A care plan has been developed based on the situation of Frank and his family. (See the care plan at the end of this chapter.)

Planning Interventions

Rather than emphasizing the chronic health issues and related problems, the nurse can begin with asset planning within the family. **Asset planning** is a planning approach that, given the realities of the present, helps focus the family members and their providers on the building blocks for their future. It focuses on the assets or strengths of the individual, the family, and the community, applying those assets to improve or maintain the current level of functioning.

Frank's physician and nurse can begin with the fact that Frank survived his first myocardial infarction. The coronary damage resulting from this event becomes the baseline for determining future change in the lives of Frank and his family. Earlier, Frank's physician had taken a broader time perspective when he advised Frank to reduce his cigarette smoking, which was contributing to both his bronchitis and his hypertension, and to change his high-fat diet and sedentary habits, which contributed to his weight problem and his high blood pressure. These lifestyle changes now become tools for Frank's recovery and for change within his family. His cardiac event also becomes a risk factor for heart disease in the lives of his children.

Looking at the immediate future, Frank's employer saw the effect of the event on Frank's position within the company. Frank would have a long recovery that could be successful if he adhered to his cardiac rehabilitation program. Asset planning at this level means examining how to move Frank back into his work role without further jeopardizing his health. Frank and Sada also need to examine if he could continue in this position, given its potential effect on his health.

Frank and his family used a broader perspective than the medical personnel or the corporation. They knew that to achieve the family's

economic and educational goals and still spend time together they had to make decisions that would ultimately affect Frank's health. Similar to many Americans, they had been willing to live with Frank's job pressures and stressful lifestyle caused by the economy. The family members were aware of their impoverished roots and had no wish to return to them. However, they also recognized that the strength of their family, their ability to work together to achieve goals, and their faith were assets that could be used for support.

Frank's social network of friends, relatives, and church members became an additional asset. They helped the family through the difficult initial weeks at home by delivering meals, taking care of the yard work and laundry, and providing companionship so Sada could shop and have time alone. As Frank recovered, they would provide support for the social and lifestyle changes that Frank and his family needed to make.

The nurse-led cardiovascular rehabilitation group played a vital role in Frank's recovery. As the physician continued to monitor Frank's cardiac status, the nurse began the long process of working with Frank to modify his habits. He had stopped smoking while in the hospital, but with more free time than usual, he was craving to smoke again. Using an asset planning approach and Gordon's (2016) functional health patterns, the nurse identified the changes that Frank needed to make to decrease the risk of a second heart attack. A plan was developed to help Frank begin to take control of his life through behavior changes. These changes included relaxation techniques, diet modification, smoking cessation, and mild chair exercises. The support of the family was enlisted to reinforce the changes Frank was willing to make, because social support and environmental changes are shown to enhance personal decision-making. His employer was contacted and agreed to a plan enabling Frank to work from home using a computer while the workplace became smoke-free. Frank became an asset to the workplace, serving as a spokesperson for the benefits of lifestyle change. He was enlisted to talk with other employees about stress management, exercise, weight reduction, and smoking cessation based on his personal experiences.

Health planners and public health officials used the broadest perspective in asset planning by viewing Frank as an example of a person whose potential shifted as a result of a preventable, disabling illness. The planners looked to public and private community patterns and policies that increase healthful habits and living conditions. Work schedules and work load; stress and safety in work environments; affirmative action programs for jobs and wages; availability of public transportation systems, recreational facilities, and economically accessible housing; farm price subsidies for food and tobacco crops that affect buying patterns; excise taxes and regulation of health-damaging drugs such as alcohol and nicotine were all taken into consideration (Grzywacz & Fuqua, 2000). The asset planning approach emphasized the positive actions that could be made at the personal, employment, community, and societal levels to minimize the effects of Frank's illness and related diseases, thereby addressing all levels of the ecological model of health.

What Was the Actual Cause of Frank's Problem?

It is not possible to separate one cause from another because heart disease is a multifactorial disease. In Frank's case the sources of illness were found in the many interrelationships in his life. Attempting to treat or change each factor as a separate entity can have only a limited effect on the improvement of overall health. Frank's health problems were numerous. In addition to a poor diet, weight gain, lack of exercise, and smoking, his hyperlipidemia, an adaptive biological response to the pressures in his life, further debilitated him. It eventually led to clogged coronary vessels, and his responses became maladaptive. His hypertension, resulting from his diet and time-constrained lifestyle, complicated by the buildup of plaque secondary to hyperlipidemia, was also a biological attempt to adjust to a situation that contributed to an imbalance between his personal resources and the demands of his family and the economic world. Frank's smoking was a psychosocial means to help him relieve some of the emotional pressures. It may have served this short-term purpose, but only at a silently rising cost to his health. Cigarette use

by persons who have hypertension or high serum cholesterol levels multiplies their risk of coronary heart disease (Izzo & Black, 2008).

Evaluation of the Situation

The health status of an individual or population depends on a sustainable balance of the complex responses between physiological, psychological, and social and environmental factors. Health was initially conceived as a biological state, with genetic endowment as the starting point. However, health involves psychological and social aspects and is interpreted within the context of the immediate environment.

The interconnections between biophysical, psychological, and environmental causes and consequences did not end with Frank's heart attack. His heart attack was only the most dramatic sign that health-damaging responses outweighed health-promoting ones. The "tip of the iceberg" analogy is frequently used to illustrate the importance of identifying individuals with subclinical symptoms. High blood lipid levels, high blood pressure, obesity, smoking, and persistent worrying were no less important than the infarction in shaping the status of Frank's health. Repairing the damage to Frank's heart without changing his lifestyle, habits, and work environment would only buy a brief amount of time before further damage would occur.

The infarction and resulting disability also permanently reshaped Frank's environment. After a few months of working full-time, Frank realized that he needed to find a less stressful job. He recognized that his sales administration skills were an asset and began interviewing in the nonprofit sector. Ultimately, he landed a job at half his previous salary, but with excellent benefits and a flexible work environment. His reduced income meant that his children's educational opportunities were more limited than they were before his heart attack, but his family responded by seeking tuition support from community organizations. Frank found that his contacts in both the corporate and the nonprofit sectors increased his value to his new employer. Frank's entire life, internal and external, had changed. He

had learned to adapt to his health problems and had developed a more **eudaimonistic** approach to health and life.

Frank's situation illustrates how causes and effects in life and health tend to merge into constant, inseparable interconnections between individuals and their worlds. A person's health status is a reflection of a web of relationships that characterize that person's life. Health is not an achievement or a prize but a high-quality interaction between a person's inner and outer worlds that provides the capacity to respond to the demands of the biological, psychological, and environmental systems of these worlds.

Which of the *Healthy People 2020* focus areas listed in Box 1-4 apply to the promotion of Frank's health?

Clearly, the area of heart disease and stroke is most applicable. The *Healthy People 2020* website (https://www.healthypeople.gov/2020/default) has a number of objectives that relate directly to the prevention of heart disease, hypertension, and hyperlipidemia, including objectives that relate to treatment options and training the public to recognize and respond to nutrition and weight (Box 1-5: *Healthy People 2020*). From the information about Frank and his experience, determine what his children should be taught on the basis of the *Healthy People 2020* objectives in this focus area.

Care Plan

Health Assessment: Frank Thompson and Family

***NURSING DIAGNOSIS: Risk of ineffective coping as a result of change in role performance and self-esteem**

Defining Characteristics

- Inability to complete tasks
- Lack of focus on needs

- Feelings of inadequacy
- Inability to make decisions
- Sense of being overwhelmed
- Rest and sleep disturbance
- Frequent stress-related headaches
- Emotional fragility
- Assessment of situations does not match assessments of others

Related Factors

- Unexpected life changes
- Diagnosis of chronic disease
- Stressful life events
- Unsure of family supports
- Unrealistic expectations of self
- Unpredictable future
- Need to reassess abilities
- Insecure job status

Expected Outcomes

- The person will develop realistic expectations of capabilities on the basis of rehabilitation potential.
- The nurse and person will set mutually agreeable milestones for

resuming functions.

- The person will develop a revitalized sense of self.
- The person and family will use available resources to examine social and role shifts that affect the family.
- The person and spouse will express to each other their hopes and fears about the future.

Interventions

- Listen to the concerns of the person and spouse regarding job, social, family, and medical concerns.
- Counsel the individual and spouse about realistic goals and expectations of cardiac rehabilitation.
- Assist the individual in setting realistic and reachable short-term goals.
- Assist the individual in developing more effective problem-solving skills.
- Provide support and positive feedback as short-term goals are met.
- Explore available community services that match the goals of the family.
- Facilitate family access to needed services through advocacy and supportive guidance.
- Supervise and teach about the use of prescribed and other medications.
- Coordinate communications between providers, employers, and other organizations to meet coping needs of the individual and his

or her family.

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses - Definitions and Classification 2015-2017. Copyright © 2014, 1994-2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

The ways individuals define health and health problems are important because definitions influence attempts to improve health and care delivery. In the case study, Frank Thompson's health was affected by obvious, immediate, and personal factors, such as his diet and employment pressures. Nevertheless, his problems had their roots in the social and economic conditions of his parents; in his own early history of illness, education, and work; and in his and his family's hopes and aspirations. His physician defined Frank's problem in immediate biomedical terms. Public health planners, who saw Frank's problem on a longer-term population basis, sought policy solutions to the problem of preventing cardiovascular disease.

The view taken in this text is that a broad and longer-term perspective of health is the best guide to promoting health more effectively, even as nurses deal with individual problems on a daily basis. Health is a sustainable balance between internal and external forces. Health allows people to move through life free from the constraints of illness and promotes healing.

Illness represents an imbalance that human choices (intertwined social, political, spiritual, professional, and personal choices) create. In the United States, communities may still have time to reduce the onslaught of chronic disability and shift the direction, slow the pace, and humanize the scope of economic and social life.

Shifting directions in today's health care patterns may be possible only when nurses and other health professionals do what is expected of them as leaders in the care of health: to work with others through open processes; to provide leadership in finding the vision and the path; and to inform, educate, and reeducate themselves, their colleagues, the media, and the general public using research findings and evidence-based practice methods.

The responsibility of nurses as health professionals today is to see the health problem in new ways and help others to do the same. Responsibility means developing new roles and examining the

problem through others' viewpoints, including those of individuals, the public, other professionals, and other nations. Responsibility also means evaluating the social and individual consequences, the long-term and short-term effects, and the public and private interests that are involved when one is deciding on the set of tools to use in the care of health.

Emerging Populations and Health

Kevin K. Chui, Frank Tudini, Sheng-Che Yen

OBJECTIVES

After completing this chapter, the reader will be able to:

- Differentiate among ethnicity, ethnic group, race, and minority group.
- Describe demographic data relative to emerging populations:
  - Arab Americans
  - Asian Americans/Pacific Islanders
  - Black/African Americans
  - Latino/Hispanic Americans
  - Native Americans
  - Homeless persons
- Describe health concerns and issues of emerging populations.
- Discuss selected cultural factors that may have an impact on the health and well-being of emerging populations.
- Contrast the folk healing system with the professional care system.
- Explain strategies for health care professionals to meet the needs of emerging populations.
- Describe initiatives to address the health care concerns of emerging populations.

Think About It

A New Brand of Outreach for Chemically Dependent Homeless People With HIV/AIDS

- Access to health care services is often a major barrier for people who are considered underserved by the health care system. Community outreach programs have shown some success in reaching persons with different types of health problems. However, outreach programs for certain marginalized populations have not always been successful in their efforts to reach the "hard to reach."

- A new approach in outreach programs for chemically dependent homeless people with HIV/AIDS is harm reduction. This approach "acknowledges the reality that drug use is a part of life. Rather than condemn or condone, harm-reduction practitioners seek to work collaboratively with the client."

- Harm reduction as a part of outreach programs:

- Aims to build on the ability of individuals to make decisions about their own lives.

- Views drug use along a spectrum, ranging from heavy use to abstinence.

- Honors self-determination and individual dignity.

- Functions as an alternative model of treatment that reinforces a hierarchical physician-patient relationship.

- Practitioners who view harm reduction as an essential component of outreach:

- See their patients as experts of their lives and their addiction.

- Consider the structural factors that influence adoption of healthy lifestyles.
- Facilitate an egalitarian relationship between the patient and the provider.
- Consider all the multiple pressures affecting patient functioning in all spheres of life.

With these premises and beliefs, an outreach program explored the service utilization of chemically dependent persons with HIV/AIDS. The study's purpose was to investigate whether hard-to-reach participants, lodged through a harm-reduction program at single-room occupancy hotels, access health services at the same level as those who report at the agency's drop-in center. Data indicate that low-threshold harm-reduction outreach did increase access to health services by reducing barriers to services.

The researcher concluded that this component of outreach is a "valuable intervention for increasing utilization among this highly marginalized group." Will this philosophy of outreach be effective in helping persons with chronic illnesses such as diabetes, hypertension, or obesity, to name just a few? Something to think about!

More comprehensive information on the harm-reduction approach for chemically dependent individuals with HIV/AIDS is available online at http://www.aids.org/topics/harm-reduction-and-hiv/.

Health Disparities and Health Equality

Many magnitudes of disparity, particularly in health, exist within the United States and across countries (World Health Organization, 2015). There has been a growing awareness that racial and ethnic minority groups experienced poorer health compared with the general population in the United States. Various factors such as race or ethnicity, sex, age, disability, and socioeconomic status contribute to an individual's capability to attain good health, which is a function of one's ability to receive quality care and have access to health care (Agency for Healthcare Research and Quality, 2011). *Healthy People 2020* (http://www.healthypeople.gov) endeavors to improve the health of all groups (Hansen, 2011).

Health disparities is an umbrella term that includes disparities in health and in health care. It was defined by *Healthy People 2020* as "a particular type of health difference that is closely linked with social, economic, and/or environmental disadvantage," and "health disparities adversely affect groups of people who have systematically experienced greater obstacles to health based on their racial or **ethnic group;** religion; socioeconomic status; gender; age; mental health; cognitive, sensory, or physical disability; sexual orientation or gender identity; geographic location; or other characteristics historically linked to discrimination or exclusion" (US Department of Health and Human Services, Centers for Disease Control and Prevention, 2011). Health disparities represent a lack of efficiency within the health care system and account for unnecessary costs for and diminish the quality of life of persons seeking care (Hansen, 2011).

Health equity is the accomplishment of the highest level of health for all people. Attaining health equity requires valuing everyone equally with focused and ongoing societal efforts to deal with preventable inequalities, historical and contemporary injustices, and the elimination of health and health care disparities (US Department of Health and Human Services, Centers for Disease Control and Prevention, 2011).

Although the diversity of the American population is one of the best assets for this country, one of the greatest challenges is reducing the disparity in health status of America's racial and ethnic minorities and other health disparity populations. The US Department of Health and Human Services (US Department of Health and Human Services, 2015) and the Institute of Medicine (2008) have well documented that racial and ethnic minorities, compared with whites, have less access to health care, receive lower-quality health care, and have higher rates of illness, injury, and premature death. A review of *Health, United States, 2014: With Special Feature on Adults Aged 55–64* (National Center for Health Statistics, 2015) will help one to understand the magnitude of the problem. For example, black or African-American men and women aged 20 years or older have much higher rates of hypertension and uncontrolled high blood pressure than white men and women. The issue of racial and ethnic health disparities has become one of the most urgent problems to plague the US health care system.

Efforts to eliminate disparities and achieve health equity have focused primarily on diseases or illnesses and on health care services. However, the absence of disease does not automatically equate to good health. An individual's ability to achieve good health could be affected because of race or ethnicity, gender, sexual identity, age, disability, socioeconomic status, and geographical location.

Emerging Populations in the United States

Currently, **emerging populations** include ethnic minorities and persons who are homeless. Ethnic minority populations could include Asian Americans/Pacific Islanders (AAPIs), black/African Americans (BAAs), Latino/Hispanic Americans (LHAs), Native Americans, and Arab Americans (Box 2-1: *Healthy People 2020*). The increasing population of immigrants has been a significant contributor to the presence of increasing numbers of major ethnic groups in the United States. Between 2000 and 2013 the immigrant population in the United States increased by 10.2 million (Migration Policy Institute, 2015). The US immigrant population accounted for about 11.1% of the total US population in 2000 and 13.1% in 2013 (Migration Policy Institute, 2015). From 1960 to 2013, more than 41 million people legally immigrated to the United States with the 10 most common countries of origin being (in rank order) Mexico, China, India, Philippines, Vietnam, El Salvador, Cuba, Korea, Dominican Republic, and Guatemala (Migration Policy Institute, 2015). In addition, there are approximately 11 million unauthorized immigrants in the United States, with Mexicans representing the majority (56%, or approximately 6 million) (Rosenblum & Soto, 2015). One in three Americans in the United States identifies as African American, American Indian/Alaska Native (AIAN), Asian, Native Hawaiian/Pacific Islander, Hispanic/Latino, or multiracial. It was estimated that this number is expected to increase to one in two Americans by 2050 (Kaiser Family Foundation, 2008). The increasing populations of ethnic groups are one of many factors producing disparities in health status and access to the health care system in the United States. The disparities in the health care system may cause increases of social costs attributable to the lost productivity or use of health care services among the ethnic minority populations.

Box 2-1

Healthy People 2020

Selected National Health Promotion and Disease Prevention Objectives for Emerging Populations

- Increase the number of people with health insurance to 100% (baseline, 83.2% [lower in ethnic minorities] of people younger than 65 years covered by health insurance in 2008).
- Increase the proportion of people who have a specific source of ongoing care to 89.4% (baseline, 81.3% in 2008).
- Reduce the overall cancer death rate. Target of 161.4 deaths per 100,000 of the population (baseline, 179.3 deaths per 100,000 of the population in 2007).
- Prevent diabetes. Target of 7.2 new cases per 1000 per year, ages 18 to 84 years (baseline, eight new cases in past 12 months, as reported in 2006-2008) Increase the proportion of people with diabetes who receive formal diabetes education. Target of 62.5% (baseline, 56.8% of people with diabetes received formal education in 2008.)
- Reduce coronary heart disease deaths. Target of 103.4 deaths per 100,000 (baseline, 129.2 coronary artery disease deaths per 100,000 in 2007).
- Reduce AIDS among adolescents and adults. Target of 12.4 new cases per 100,000 (baseline, 13.8 cases of AIDS, aged 13 years or older in 2007).
- Increase the number of population-based data systems used to monitor data on (or for) lesbian, gay, and bisexual populations. Target of 12 data systems used to monitor data (baseline, 6 data systems used to monitor data in 2008).

Ethnicity, Ethnic Group, Minority Group, and Race

Race and ethnicity categories in the United States are defined by the Office of Management and Budget, with the latest set based on a 1997 revision of a 1977 standard (Humes et al., 2011). The minimal race categories for collecting data on race and ethnicity are black/African American (BAA), American Indian/Alaska Native (AIAN), Asian, Native Hawaiian and other Pacific Islander, and white; and the minimal ethnicity categories are Hispanic/Latino and non-Hispanic/Latino origin (Humes et al., 2011).

Race and ethnicity are different but somewhat alike. Race is associated with power and indexes the history or ongoing imposition of one group's authority above another. Ethnicity focuses on differences in meanings, values, and ways of living (practices) (Markus, 2008). **Race** has been defined as "a dynamic set of historically derived and institutionalized ideas and practices that: sorts people into ethnic groups according to perceived physical and behavioral human characteristics; associates differential value, power, and privilege with these characteristics and establishes a social status ranking among the different groups; and emerges (1) when groups are perceived to pose a threat (political, economic, or cultural) to each other's worldview or way of life; and/or (2) to justify the denigration and exploitation (past, current, or future) of, and prejudice toward, other groups" (Markus, 2008). A definition provided for **ethnicity** is that "ethnicity is a dynamic set of historically derived and institutionalized ideas and practices that allows people to identify or to be identified with groupings of people on the basis of presumed (and usually claimed) commonalities including language, history, nation or region of origin, customs, ways of being, religion, names, physical appearance, and/or genealogy or ancestry; can be a source of meaning, action, and identity; and confers a sense of belonging, pride, and motivation" (Markus, 2008).

A **minority group** consists of people who are living within a society in which they are usually disadvantaged in relation to power, control of their own lives, and wealth (Hammond & Cheney, 2009). For example, poverty rates for Native Americans and Alaskan Natives (27.0%) and blacks or African Americans (25.8%) are much higher than the overall poverty rate (14.3%) and that of whites (11.6%) and Asians (11.7%) (McCartney et al., 2013). In the 2010 US Census, just one-third of the US population reported their race and ethnicity as something other than non-Hispanic white alone, and this group was referred to as the "minority" population for the report (Humes et al., 2011). The minority population in the United States increased from 86.9 million to 111.9 million between 2000 and 2010, representing a growth of 29% during the decade (Humes et al., 2011).

Culture, Values, and Value Orientation

Ethnicity is evidenced in customs that reflect the socialization and cultural patterns of the group. **Culture,** as an element of ethnicity, refers to integrated patterns of human behavior that include the language, thoughts, communications, actions, customs, beliefs, values, and institutions of racial, ethnic, religious, or social groups (Office of Minority Health, 2016a). It is "shaped by values, beliefs, norms, and practices that are shared by members of the same cultural group" (Giger, 2013).

Values are beliefs about the worth of something and serve as standards that influence behavior and thinking. Cultural values "are unique, individual expressions of a particular culture that have been accepted as appropriate over time. They guide actions and decision-making that facilitate self-worth and self-esteem" (Giger, 2013). Cultural values are integral to the manner in which individuals will employ health behaviors, maintain their health, how they will seek care for themselves and others, and where they are likely to go to receive care (Boyle, 2016).

Value orientations, learned and shared through the socialization process, reflect the personality type of a particular society. The dominant value orientations are shared by the majority of the group. Kluckhohn's model (1953) of value orientations incorporates themes regarding basic human nature, the relationship of human beings to nature, human beings' time orientation, valued personality type, and relationships between human beings.

Ethnic groups have their unique beliefs and attitudes about health and health care services (Box 2-2: Diversity Awareness). Incongruent beliefs and attitudes about health and health care services among ethnic groups versus the rest of the population, particularly health care providers, are major barriers in improving the health status of ethnic group members. Health care providers need to become responsive to the cultural values of different peoples and to realize how this cultural understanding could augment effective and

humanistic care delivery. Knowledge and culturally competent practices are essential for nurses to function effectively in rapidly changing multicultural societies to provide quality and safe care to all.

Box 2-2

Diversity Awareness

Female Genital Mutilation: Taboo or Tradition

Some practices of individuals or groups are deeply rooted in beliefs connected to culture. These practices are considered unhealthy and/or unsafe in other cultures who do not share the same beliefs. This is the case for **female genital mutilation (FGM).** What is the likelihood of health care providers having an encounter with circumcised women? It is probably high because "although the incidence of FGM in women is worldwide, rough estimates range from 114–130 million women" (Little, 2003). The increasing migration of circumcised women to the United States and the fact that "female circumcision has been practiced in the US since the 19th century" (Webber & Schonfeld, 2003) increase the probability of these women's presence in health care settings. In countries that legally prohibit FGM, parents often feign a holiday or vacation to the native country, where they have the young daughter circumcised.

Female circumcision and female genital mutilation have unknown origins. However, it is believed that the practice can be traced "in Africa as far back as the 5th century B.C. and has taken place in ancient Egypt, ancient Rome, Arabia, and Tsarist Russia" (Little, 2003). There are four types of FGM:

- Type 1, also known as clitoridectomy, is the excision of the clitoral prepuce and may also involve the excision of all or part of the clitoris.
- Type 2 is the excision of the clitoris and may also involve the excision of all or part of the labia minora.

- Type 3, also known as infibulation, involves excision of part or all of the external genitalia and the stitching or narrowing of the vaginal opening.

- Type 4 refers to all other genital procedures (Momoh, 2004).

It is a myth that FGM is advocated by specific individuals in cultures or societies that advocate and support this practice. Leval et al. (2004) analyzed the ways Swedish midwives discussed sexuality in circumcised African women. Their encounters with spouses in maternity wards dispelled the myth that men are the power holders. They were described as "always tender, caring, power shares, or even subordinates in the relationship." Support for this myth buster is seen in societies where adult women advocate and support the practice as an affirmation of their roles and high regard for their bodies (Little, 2003). Parents of young girls support the practice as an assurance of economic security for their daughters (Gruenbaum, 2005). In some societies, powerful women leaders who are feared and respected promote this practice (Little, 2003).

There are many explanations for female circumcision. Gruenbaum (2005) offers a comprehensive discussion of these. Her analysis to approaches for proposed changes in the practice or its elimination through the passage of laws is extremely enlightening and provides a deep understanding of the complexities of FGM. There are cultural reasons for this practice, including providing health benefits, preserving virginity before marriage, serving as a rite of passage, and providing economic security for women as well as for the people performing such acts (Berg et al., 2009; Gruenbaum, 2005; Little, 2003). Cultural beliefs about sexuality and sexual responses are also a factor (Leval et al., 2004).

FGM has many complications. The immediate ones include hemorrhage, infections, abscesses, and urinary difficulties such as retention and straining. Long-term complications include difficulty voiding, urinary and reproductive tract infections, and incontinence. Other complications are infertility, painful intercourse, keloids, introital and vaginal stenosis, dermoid cysts, and pain. For the

circumcised woman during labor, there is obstructed labor, fetal distress, perineal tears, perineal wound infection, and postpartum hemorrhage and sepsis. Obermeyer (2005) contends that complications or consequences of FGM are poorly documented because of many methodological issues, including the quality of the data collected. Valid research on female circumcision is a fertile ground. Obermeyer's (2005) review of studies on FGM is an excellent resource for interested researchers.

What are the care implications for nurses? Midwives and nurses whose area of practice is women's health are more likely to have experiences with circumcised women. “It is essential that midwives recognize the cultural complexities of FGM and show sensitivity when caring and supporting women with FGM during pregnancy, labour, and the postnatal period” (Momoh, 2004). Identification can start by asking questions such as the following: “Have you been closed?” “Did you have the cut or operation as a child?” Referrals to a specialist would facilitate discussion of legal issues and possible reversal of the procedure (infibulation). Procedures to reverse infibulation during labor might be performed. Other invasive procedures need to be avoided to eliminate possible sources of pain and stress.

Following delivery, before reinfibulation or restitching is done, the health care provider needs to consider the laws governing the practice of FGM. The mother and the baby, if female, are cared for with a view toward the future of the baby.

The information presented is but a very small representation of the continuing interests and work of people from diverse backgrounds. One powerful statement made by these scientists and caregivers is that whatever is done to eliminate FGM, “the cultural integrity of the people” (Little, 2003) must be preserved. Readers are strongly urged to read the cited references for a fuller understanding of FGM.

Cultural Competency

Culture may have an impact on people's health, healing, wellness belief systems, perceived causes of illness and disease, behaviors of seeking health care, and attitudes toward health care providers. Culture may also influence the delivery of health care services by the providers, who use their own limited set of values to view the world.

Every culture has diverse illustrative models of illness and belief systems regarding health and healing. These models and wellness belief systems include views about the pathophysiology of diseases, the cause and the onset of symptoms, the natural history of illnesses, and the appropriate treatments for various health issues.

Cultural competency is one of the major elements in eliminating health disparities; it starts with an honest desire to disregard personal biases and to treat every person with respect. Cultural competence is a broad concept used to describe interventions to improve quality and access to health care for minorities (Truong et al., 2014) and a dynamic process that requires lifelong learning (Moore et al., 2010). Although the number of racial and ethnic populations is growing in the United States, it has produced a challenge to the system of health care delivery services. Health care providers and persons seeking care bring their individual cultures and health beliefs and values to the health care experience. Hence understanding the cultural underpinning of care is a challenging task because of the complexity and interaction between the person seeking care and the health care provider's cultural beliefs (Salman et al., 2007). In addition, providing health care services that are respectful of and responsive to diverse individuals' health beliefs, practices, and cultural needs is believed to contribute to fewer negative health outcomes (Management Sciences for Health, n.d.; Office of Minority Health, 2016a).

It is very important for health care providers to be aware of how persons interpret their health issues or illnesses and to be capable of providing culturally competent care. Simply recognizing and accepting cultural diversity is insufficient to attain cultural

competency in health care. Culturally competent health care professionals should be able to consistently and thoroughly recognize and understand the differences in their culture and the culture of others; to respect others' values, beliefs, and expectations; to understand the disease-specific epidemiology and treatment efficacy of different population groups; and to adjust the approach of delivering care to meet each person's needs and expectations (Management Sciences for Health, n.d.). Cultural competency is usually reflected in a health care provider's attitude and his or her communication style.

Douglas and colleagues (2014) discuss universally applicable guidelines for achieving culturally competent care. Their guidelines include knowledge of culture; education and training in culturally competent care; critical reflection; cross-cultural communication; culturally competent practice; cultural competence in health care systems and organizations; patient advocacy and empowerment; a multicultural workforce; cross-cultural leadership; and evidence-based practice and research. For each guideline they discuss strategies and provide implementation examples for caregivers and health care organizations' leaders/managers.

Truong and colleagues (2014) conducted a systematic review of reviews on the effectiveness of interventions to improve cultural competence in health care. Nineteen reviews were included that examined a variety of health care contexts (i.e., a variety of minority populations, diseases, health care settings and professionals, and interventions). In this systematic review, three main types of outcomes were reported: patient-related outcomes, provider-related outcomes, and health service access and utilization outcomes. Most of the reviews reported moderate-level evidence for improvements in provider-related outcomes and health service access and utilization outcomes. Some, but weaker, evidence was reported for patient-related outcomes. Unfortunately, many of the self-reported measures, such as patient- and provider-related outcomes, used tools that were not validated.

Recently researchers have established and tested the Cultural

Competence Health Practitioner Assessment (CCHPA-67), which purports to determine levels of cultural and linguistic competence (Haywood et al., 2014). The 67-item questionnaire has three domains; —knowledge, adapting practice, and promoting health—and has sound clinometric properties, including reliability and validity. CCHPA-67 can be used to examine the effectiveness of interventions to increase cultural and linguistic competence of health care practitioners and the association between their level of competence and health care outcomes.

Folk Healing and Nursing Care Systems

Within its cultural and/or ethnic customs and traditions, each group has a healing system that incorporates the beliefs and practices deemed essential in maintaining and restoring health. Three components of the healing systems of people were defined: self-care, **nurse care systems,** and folk healing systems (Andrews, 2016). Nurse care is characterized by specialized education; advanced knowledge, skills, and abilities; responsibility; and expectation of remuneration of services provided (Andrews, 2016). A **folk healing system** embodies the beliefs, values, and treatment approaches of a particular cultural group that are products of cultural development. Folk health practices are seen in a variety of settings, including community groups, kinship groups, private homes, and healers' shrines. Unlicensed practitioners such as lay midwives, bone setters, and herbalists are part of the folk sector, as are religious practitioners such as spiritualists, Christian Scientists, and scientologists.

The choice of a health care system differs among ethnic groups and among individuals within the same group. Ethnic individuals' preference for their folk healing systems is motivated by their familiarity with the folk healer, who usually speaks the same language and is knowledgeable about the beliefs, customs, and traditions of the ethnic group. Easy access and the individual's ability to pay for the healer's services are real advantages when compared with the difficulty of getting appointments, the long waits, and the unfamiliar institutional settings in the professional care system. Despite ongoing developments in treatments provided by **professional care systems**, many folk healing practices maintain their popularity today. When folk healing practices are not effective, the individual may, as a last resort, turn to the professional care system. Through a culturally sensitive assessment process, nurses can determine which specific folk remedies individuals are using and

whether their continued use would interfere with the prescribed medical regimen. Andrews and Boyle (2016) and Giger (2013) have developed transcultural assessment guides, such as the Andrews & Boyle Transcultural Nursing Assessment Guide, that nurses can use when working with ethnically diverse individuals. Nurses must avoid an ethnocentric perspective when working with ethnic groups. An **ethnocentric perspective,** which views other ways as inferior, unnatural, or even barbaric, can serve as a major obstacle in establishing and maintaining good working relationships with consumers of health care services.

Ethnic groups will continue to use folk remedies and healing. Therefore nurses need to appreciate the many positive aspects of folk systems. A caring, holistic approach that incorporates family and support systems and considers the individual's viewpoint is one of the more positive aspects of folk systems. This approach is receiving recognition by the professional care system. A blend of both systems would optimize health care for ethnic Americans.

Arab Americans

Arab Americans came to the United States in three immigration waves. The first wave of immigrants, who came between the late 1800s and World War I, were mostly from Greater Syria. The second wave came after the close of World War II and included many Muslims and refugees displaced by the 1948 Palestine War. The last wave occurred in the 1960s and consisted of many professionals, entrepreneurs, and skilled and semiskilled laborers (Abraham, 2014; Stussy, 2000).

The 2000 US Census was a milestone survey because for the first time it recognized Arab Americans as a separate ethnic group. Anyone from the following countries was considered to be of Arab ancestry: Algeria, Bahrain, Egypt, United Arab Emirates, Iraq, Jordan, Kuwait, Lebanon, Libya, Morocco, Oman, Palestine, Qatar, Saudi Arabia, Syria, Tunisia, and Yemen. The number of Arab Americans grew from approximately 850,000 in 1990 to approximately 1.2 million in 2000.

From 2006 to 2010, the American Community Survey 5-year estimates indicated that approximately 1.5 million people (0.5% of the total population) living in the United States has Arab ancestry (Asi & Beaulieu, 2013). On the basis of the 2010 US Census, there are approximately 1.7 million Arab Americans.

The six largest groups (in rank order) of Arab Americans are the Lebanese, Egyptians, Syrians, Iraqi, Palestinians, and Moroccans (US Census Bureau, 2016) Arab Americans live in all 50 states, but one-third of them live in California, Michigan, and New York. About 94% of Arab Americans live in metropolitan areas. The top five metropolitan areas of Arab American concentration are Los Angeles, Detroit, New York City/New Jersey, Chicago, and Washington, DC. One of the largest groups of Arab Americans live in Dearborn, Michigan (Arab American Institute Foundation, 2011). Three major religions represented among Arab Americans are Christianity, Judaism, and Islam (Arab American Institute Foundation, 2011). More

than 45% of Arab Americans have a bachelor's degree or higher, compared with 28% of Americans at large. About 18% of Arab Americans have a postgraduate degree, which is nearly twice the American average (10%). Other statistical data and information on Arab Americans can be found at the website of the Arab American Institute (http://www.aaiusa.org/).

Health Care Issues of Arab Americans

There is limited health-related information and a scarcity of scholarship about Arab Americans. Similar to other ethnicities, Arab Americans have chronic health problems such as diabetes and coronary artery disease. Several factors place Arab Americans at high risk of developing adult-onset diabetes and cardiovascular disease, including obesity, age, gender, and low employment rates (Box 2-3: Genomics). Tailakh and colleagues (2012) examined the prevalence, awareness, treatment, and control of hypertension among Arab Americans by using a cross-sectional design. The prevalence of hypertension was high, with 36.5% of the sample having hypertension and 39.7% being pre-hypertensive. Of those with hypertension, only 67.4% were aware of their condition and only 52.2% were taking antihypertensive medication. Other significant findings included a higher prevalence in males than in females and a higher body mass index (BMI) in those with hypertension compared with normotensive participants. The study concluded that hypertension is a major health problem among Arab Americans and that prevention and treatment strategies are urgently needed for this population.

Box 2-3

Genomics

A recent review on obesity-linked diabetes in the Arab world discusses a growing of evidence to support a genetically based association between obesity and diabetes in Arab populations. In addition to diet, physical activity levels (including social cultural barriers for women), and decreased level of awareness regarding the

complication of obesity, there are genetic implications. Several studies on Arab populations have reported variations in the ADIPOQ gene that may affect the risk of type 2 diabetes, the risk of insulin sensitivity in obese diabetic individuals, and correlate with body weight, waist circumference, body mass index, and percentage of total body fat.

From Abuyassin, B., & Laher, I. (2015). Obesity-linked diabetes in the Arab world: A review. *Eastern Mediterranean Health Journal, 21*(6): 420-439.

Another health concern is mental health and the role of acculturation in Arab Americans. Aprahamian and colleagues (2011) looked at the concept of mental health and the degree of acculturation and the implications for mental health counselors of Arab American individuals. They reported that age at migration, length of stay in the United States, religion, and discrimination experiences were significant predictors of mental health. Mental health counselors need to be aware of and consider these factors when helping Arab American individuals. Many Arab Americans seek their immediate and extended family, community, and traditional values and cultural practices for help during a health crisis. Consequently, given the unique nature of mental illness, many Arab Americans do not receive professional mental health attention when needed.

A health issue on the rise among Arab American adolescents is tobacco consumption, which is considered to be a major risk factor for many health problems affecting the respiratory and cardiovascular systems. Tobacco can be consumed in many ways; however, tobacco chewing, cigarette smoking, and use of a shisha (water pipe) are the three major methods used to consume tobacco products. Arabs, both men and women, have long traditions of using a water pipe and smoking cigarettes with their friends and families and at other social gatherings. Weglicki and colleagues (2008) reported that the percentage of Arab American youth smoking cigarettes was lower than that of non–Arab American youth. However, water pipe smoking was seen more often in Arab American youth when compared with non–Arab American youth. Tobacco use has been

linked to a higher rate of chronic health problems such as heart disease, hypertension, and diabetes among Arab Americans than among non–Middle Eastern whites (Jamil et al., 2008). Current water pipe use has been better predicted by Arab ethnicity and a lower educational level. In another study on water pipe use, researchers examined nicotine dependence and barriers to cessation in Arab Americans who self-identified themselves as smokers (El-Shahawy & Haddad, 2015). Participants were divided into two groups, those who smoked cigarettes exclusively and those who were dual smokers (i.e., smoked cigarettes and used a water pipe). Dual smokers smoked significantly more cigarettes per day and had significantly higher scores for nicotine dependence and barriers to cessation (including addiction and external barriers). The water pipe seems to increase the addictive properties of cigarettes and increase barriers to cessation in this population of Arab Americans.

Access to culturally suitable and current care is essential given that the Arab American population suffers from a wide spectrum of diseases. Many barriers exist that prevent Arab Americans from using professional care services. Discrimination of Muslims or "Islamophobia" since 9-11 has further contributed to physical and mental health disparities in the United States and the United Kingdom (Liard et al., 2007). Additional barriers include religious beliefs and practices, cultural norms relating to modesty, family values of upholding the family's reputation, gender issues such as preference for a same-sex health provider, use of folk remedies, and stresses of assimilation and acculturation such as lack of English skills (Figure 2-1). There are also barriers related to the health providers, including a lack of culturally competent services and the possession of attitudes such as stereotyping and discrimination (Williams et al., 2008).

FIGURE 2-1 One cultural norm of the Maori in New Zealand is to say goodbye by rubbing noses.

Selected Health-Related Cultural Aspects

Arabs value the family and the ties it maintains; therefore the extended family, a clan, and a tribe are common kinship groups. Customs center on hospitality around food, family, and friends (Andrews, 2016). Arab American families are, on average, larger than non–Arab American families and smaller than families in Arab countries. According to the American Community Survey (Asi & Beaulieu, 2013), the average size of an Arab American household was 2.93 people, compared with the national average of 2.59 people. Yemeni averaged more than four people per household, and Palestinian, Jordanian, and Iraqi averaged more than three people per household. Traditionally, more children meant more pride and economic contributors for the family. The cost of having large families

in the United States, however, and adaptation to American customs seem to encourage smaller families. Religion plays an important part in Arab culture, and there are dietary rules and prescribed rituals for praying and washing (Ehrmin, 2016). In addition, Arab Americans are present oriented and view the future as uncertain (Ehrmin, 2016).

Asian Americans/Pacific Islanders

Asian Americans/Pacific Islanders (AAPIs) represent people from many different countries, so their origins, cultures, lifestyles, and religions are diverse, and they speak more than 100 languages and dialects (Africa & Carrasco, 2011). The six most common countries of origin are (in rank order) China, Philippines, India, Vietnam, Korea, and Japan. The number of AAPIs (alone or in combination) in the United States is about 17.3 million on the basis of 2010 US Census data, which represents an increase of 5.4 million since 2000 (Hoeffel et al., 2012).

Beginning in 1997, the Asian or Pacific Islander racial category was separated into two categories (one being Asian and the other being Native Hawaiian and other Pacific Islander) by the Office of Management and Budget directive (US Census Bureau, 2016.) "Asian" refers to a person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent (Humes et al., 2011). According to the 2010 US Census, the estimated number of US residents of Asian descent corresponded to 5.6% of the total US population. Between the 2000 census and the 2010 census, Asian American and Pacific Islanders were the fastest growing (46% of growth) ethnic minority in the United States. In 2009 Chinese Americans were the largest Asian group, and following Spanish, Chinese was the most widely spoken non-English language in the United States. Most AAPIs live in metropolitan areas; California (5.6 million, or 14.9% of its population) is the state with the largest Asian population, followed by New York (1.6 million, or 8.2%) and Texas (1.1 million, or 4.4%) (Hoeffel et al., 2012). In Hawaii, 57% (or 781,000) of the total population are Asians. New Jersey also has a large concentration of AAPIs, where they represent 9.0% (or 795,000) of the total population.

AAPIs are often referred to as a "model minority"; this stereotype is frequently accepted because most AAPIs are viewed as being successful, resilient, hardworking, intelligent, and healthy. Education

is highly valued in the AAPI communities. According to the reports from the US Census (Ryan & Bauman, 2016; US Census Bureau 2015a), Asian Americans have the highest percentage of college graduates of any racial or ethnic group. About 54% of Asian Americans have a bachelor's degree or higher level of education, compared with 32.5% of the total population in the United States. Approximately 17.2% of Asian Americans reported having no health insurance coverage in 2009. Native Hawaiians or Pacific Islanders refers to people having Hawaii, Guam, Samoa, or other Pacific Islands as origins (Humes et al., 2011). According to the 2010 US Census, Native Hawaiians and other Pacific Islanders formed the largest proportion of the total population in Hawaii. Among those who identified themselves as Native Hawaiian and other Pacific Islander, the poverty rate was 19%, and 20.7% of adults aged 25 years or older had a bachelor's degree or higher. Approximately 14.1% of Native Hawaiians and other Pacific Islanders were reported as being without health insurance (DeNavas-Walt, et al., 2013) A look at the status of AAPIs as a group reveals that they are doing relatively well in the United States. For instance, the median family income is higher than the national median income for all households. Their poverty level is lower than that of other ethnic groups (US Census Bureau, 2015a).

Health Care Issues of Asian Americans/Pacific Islanders

Health care issues of AAPIs are relative to their ethnicity, religion, and status as immigrants. Some Asian American immigrants have carried diseases from their home countries, and they may now experience new diseases because of their new lifestyle and living conditions. However, AAPIs are more likely to be healthier than whites and other ethnic groups. Asian American women have the highest life expectancy (85.8 years) among all ethnic groups in the United States (Centers for Disease Control and Prevention, 2015). However, Asian Americans are challenged with various factors that threaten their health. Some negative causes are associated with infrequent medical

visits as a result of language/cultural barriers, lack of health insurance, and fear of transportation (Centers for Disease Control and Prevention, 2015; Office of Minority Health, 2016b). Asians had the highest rate of health care–associated infections when compared with other races and ethnicities admitted to hospitals for cardiovascular disease, pneumonia, and major surgery (Bakullari et al., 2014). The researchers discuss how language barriers between patients and providers may serve as a possible explanation for their findings.

In general, AAPIs have health problems similar to those of the US population as a whole. Cancer, heart disease, stroke, unintentional injuries, and diabetes are the top five leading causes of death among AAPIs (US Department of Health and Human Services, 2010). A high BMI in Asian Americans was associated with an increased risk of total death at a rate similar to that for whites and black Americans in the United States (Park et al., 2014). Asian Americans also have a high prevalence of and risk factors for chronic obstructive pulmonary disease, hepatitis B, HIV/AIDS, smoking, tuberculosis, and liver disease (Office of Minority Health, 2016c). AAPI women were 30% less likely than non-Hispanic white women to have breast cancer (Office of Minority Health, 2016c). AAPI women are less likely to die of breast cancer, and death rates are lower compared with those for the other ethnic groups. However, AAPIs are three times more likely than non-Hispanic whites to have stomach cancer. Asian/Pacific Islander men are 40% less likely than white men to have prostate cancer, but they are twice as likely to have stomach cancer. In general, AAPIs have lower rates of being overweight and having hypertension and are less likely to be current cigarette users compared with white adults. By the end of 2009, AAPI cases accounted for approximately 1% of the total HIV/AIDS population in the United States (Centers for Disease Control and Prevention, 2014). Although the numbers of infected people are low compared with the numbers in the other groups in the United States, the increased rates of HIV/AIDS infections among AAPIs from 2006 through 2009 have raised concerns about this population (Centers for Disease Control and Prevention, 2014). Native Hawaiians/Pacific Islanders have a higher prevalence of

substance abuse, depression, and delinquency when compared with Asian Americans (Wu & Blazer, 2015). Given the differences in substance abuse, mental health status, and other cultural, language, and socioeconomic characteristics, the researchers advise separating Native Hawaiians/Pacific Islanders and Asian Americans when topics that may inform health policy are being studied.

Disparities in the health status of AAPIs are primarily a result of subcultures within the larger group. There are many divergent and segregated cultures within AAPIs; however, all ethnic populations of AAPIs are currently often classified and viewed as an unvarying group. About two-thirds of AAPIs are foreign-born, whereas nearly 38% of Asian Americans do not speak English fluently (Ponce et al., 2009). The classification and cultural barriers (such as language) limit public awareness and restrain effective and culturally appropriate disease prevention for subgroups of the AAPI population. However, few studies have focused on AAPIs, and even fewer researchers have examined the subgroups, and this often creates a generalized and inaccurate picture of the experience and needs of AAPIs in the United States. The heterogeneity of subgroups among AAPIs and their relatively small representation in the US population make it challenging to have sufficient and representative samples from the AAPIs. Information about health status among the different subgroups of AAPIs is extremely limited; more studies are needed to fully understand their health issues.

Selected Health-Related Cultural Aspects

AAPIs share many traditional values. A comprehensive description of traditional values in several Asian groups indicates commonalities and differences (Andrews & Boyle, 2016; D'Avanzo & Geissler, 2008).

The family is the most important social institution for AAPIs (Kavanaugh, 2008). The extended family has significant influence on Asian Americans. Although family dynamics and structure differ in the different AAPI subgroups, the family is often the major source of functional and psychological support for AAPIs. Usually, the interests and honor of the family are more important than those of individual

family members. Older family members are usually respected and have authority that is often unquestioned. For instance, among Filipinos, calling older people by their first names is a sign of disrespect. Male friends of one's parents or grandparents are addressed as “tito” (uncle) followed by the first name. For female friends it is “tita” (aunt). These terms, denoting respect, have been substituted for Filipino terms that do not have English translations.

In the culture of Asian Americans, the oldest male family member is often the decision maker and spokesperson. Maintaining harmony is an important value in Asian cultures, and avoiding conflict and direct confrontation is strongly emphasized. Authorities and professionals are usually respected in the Asian American communities. Mostly, physicians and their recommendations are powerful and highly respected and valued. However, as a result of respect for authorities, AAPIs may avoid showing their disagreements with the recommendations of health care professionals. The health care providers need to recognize that lack of disagreement with recommended treatments or therapies does not mean that the Asian American patient and family agree with or will abide by the treatment recommendations.

The rates of psychological distress in AAPIs are similar to those in the general US population; however, AAPIs have a tendency to be the least likely to seek mental health services among all ethnicities. A variety of factors related to cultural values, such as stigma, cultural impact of shame, and language barriers, may contribute to their low utilization of mental health services (Africa & Carrasco, 2011). Asian cultures consider that the behavior of the individual reflects on the family; therefore mental illness or any behavior that indicates lack of self-control is viewed as producing shame and guilt in the family. Consequently, Asian Americans may be reluctant to discuss symptoms of mental illness or depression. Suicide was reported as the ninth leading cause of death among Asian Americans, compared with the tenth leading cause of death for white Americans; among all US women older than 65 years, Asian American women have the highest suicide rate (Office of Minority Health, 2016d).

In addition to reduced access to mental health care, the culture and values of AAPIs are associated with other health problems and risk factors that threaten health and act as barriers to accessing health care. For example, sexually related issues are taboo topics and considered a private matter that should not be discussed with anyone other than the spouse. Women may feel it is embarrassing to discuss sex, to visit physician clinics for sexually related health issues, or to receive some forms of physical examinations (e.g., Papanicolaou test). Such fears may have prohibited the willingness of AAPIs to access health care services and prevented health care providers from approaching this population for interventions. For example, the taboo topic of sexual issues was identified as one of the key barriers that makes it difficult for health care providers to approach Chinese American youths for HIV/AIDS prevention (Lee et al., 2012).

A different, but perhaps related, issue is barriers to health research participation by AAPIs (George et al., 2014). The most common barriers reported by AAPIs were mistrust, competing demands, unintended outcomes, lack of access to information, and stigma. Participants had concerns about signing the informed consent form (mistrust), which may have been related to language barriers and the lack of translated materials (lack of access to information).

Many people find the task of parenthood in a new country difficult because some of their cultural values conflict with the mainstream cultural values; for example, passivity to avoid conflict versus assertiveness. Exposure of children to different cultures in schools and in their neighborhood facilitates their adoption of other cultural beliefs and attitudes in their socialization. Additionally, the employment of immigrant women outside the home has exposed their children to other caretakers. Grandparents are often the caretakers of young grandchildren. Filipino American grandparents view their roles as part of their family responsibility (Kataoka-Yahiro et al., 2004).

Asian folk medicine and philosophies have a strong Chinese influence as a result of early Chinese migration throughout Asia. Therefore the folk medicines of Filipinos, Japanese, Koreans, and Southeast Asians are all imbued with Chinese principles. **Taoism** was

the philosophical and theoretical foundation of Chinese medicine. The "Tao" is rooted in the idea of balancing natural processes and forces (such as yin and yang) and is closely related to Asians' activities of daily living, including traditional health practices such as acupuncture, holistic medicine, herbalism, meditation, and martial arts. According to Tao doctrine, humans are microcosms within the universe. Achieving harmony between the two is essential because the energies of both intertwine. **Yin** and **yang** are the two forces that keep innate energy, called **chi,** and sexual energy, called **jing,** in balance. Yin is feminine, negative, dark, and cold; yang is masculine, positive, light, and warm. An imbalance in energy can be caused, for instance, by yielding to strong emotions or eating an improper diet. In their interactions, humans and the universe are both susceptible to the elements of earth, fire, water, metal, and wood (Andrews, 2016; Ehrmin, 2016).

Asian folk medicine uses a wide variety of herbs for healing purposes, including roots, leaves, seeds, tree bark, and parts of flowers. Some aspects of Asian folk medicine have gained popularity within the professional care system. In general, the use or nonuse of healing traditions seems to be consistent with how closely Asians identify with their heritage (Tashiro, 2006). Of these, the best known is acupuncture (Andrews, 2016). Similar alternative treatment modalities that are slowly gaining wide acceptance include meditation, therapeutic touch, massage, imagery, relaxation, and bipolarity. Box 2-4: Research for Evidence-Based Practice discusses the use of **complementary and alternative medicine (CAM)** in the United States.

Box 2-4

Research for Evidence-Based Practice

Use of Complementary and Alternative Medicine in the United States

The National Center for Complementary and Alternative Medicine (2011) defines complementary and alternative medicine (CAM) as a set of varied medical and health care practices, systems, and products that are not usually considered part of conventional medicine. Medicine is practiced by holders of doctor of medicine or doctor of osteopathic medicine degrees and by their allied health professionals such as physical therapists, psychologists, and registered nurses. Conventional medicine is also called Western or allopathic medicine and is practiced by doctors of medicine and doctors of osteopathic medicine. Doctors of osteopathic medicine are fully licensed physicians. They provide a full range of services, from prescribing drugs to performing surgery, and use a "whole person" approach to health care. They focus special attention on the musculoskeletal system, a system of bones and muscles that makes up about two-thirds of the body's mass. They may use osteopathic manipulative treatment, a system of manual therapy, to treat mechanical strains affecting all aspects of the anatomy, relieve pain, and improve physiological function. Acupuncture, biofeedback, relaxation, music therapy, massage, art, music, and dance therapy are some examples of CAM. Western medicine, supported by improved knowledge and advances in technology, has been successful in addressing numerous illnesses. However, there remains a cadre of chronic illnesses and conditions that do not respond well to allopathic treatment. People who do not experience relief from chronic conditions often resort to CAM. However, the boundaries between CAM and conventional medicine are not fixed, and several CAM practices (e.g., acupuncture and music therapy) have been becoming more widely accepted.

A national survey found that about 38% of Americans use CAM, a group of diverse medical and health care systems, practices, and products that are not presently considered to be part of conventional medicine. Complementary medicine is used together with conventional medicine, and alternative medicine is used in place of conventional medicine (National Center for Complementary and Alternative Medicine, 2011). Another study used a comparative analysis of data from the 2002 and 2007 National Health Interview

Survey of the civilian noninstitutionalized US population to investigate recent trends in CAM (Su & Li, 2011). The findings of this study suggest that CAM use has increased significantly in the United States. This increase was more obvious among non-Hispanic whites than among racial and ethnic minorities. The non-Hispanic white Americans had the highest prevalence rate of using at least one CAM therapy in the period from 2002 to 2007, followed by Asian Americans, black Americans, and Hispanics. This study also revealed that the use of CAM becomes more probable when there is limited access to conventional care. This study also pointed out that the increasing cost of conventional medical care has resulted in increasingly limited access to medical care and is a contributing factor to the rising prevalence of CAM use.

The dynamic interplay of many factors that serve as barriers for many ethnic groups to access traditional health care and the person's own cultural beliefs warrant a close look at how CAM can greatly augment health care services. This study revealed a growing prevalence of CAM use in the United States; however, the growth in CAM use was not equally distributed across racial and ethnic groups in the United States. The increasing prevalence and the increasing gap in CAM use across racial and ethnic groups highlight the critical need for assessing the health consequences of CAM therapies. There is limited information about the efficacy and the possible side effects associated with the use of any specific CAM therapy and its interactive effects with conventional medicine. More studies are needed to provide information about which CAM therapies can be used as an alternative or supplement to conventional medical care.

Trends in the use of complementary and alternative medicine in the United States: 2002-2007. *Journal of Health Care for the Poor and Underserved*, *22*, 295–309.

Latino/Hispanic Americans

The terms Hispanic and Latino are used interchangeably because the Office of Management and Budget demands federal agencies to use a "Hispanic or Latino" category to identify individuals from specific national origin. The Office of Management and Budget definition of Hispanic or Latino origin "refers to a person of Cuban, Mexican, Puerto Rican, South or Central American, or other Spanish culture or origin regardless of race." The largest Hispanic American subgroups are Mexicans, Puerto Ricans, and Cubans. Most Hispanics live in Texas, New York, Florida, and California (Office of Minority Health, 2016e). There are eight states in the United States with Hispanic populations greater than 1 million: Arizona, California, Colorado, Florida, Illinois, New Jersey, New York, and Texas.

Data from the 2010 US Census showed that the 50.5 million Latino/Hispanic people of the United States accounted for 16.3% of the total US population, making this population the nation's largest ethnic or racial minority (US Census Bureau, 2015b). There are 25 states in which Hispanics are the largest minority group. A 43% increase in the Hispanic population between 2000 and 2010 makes Hispanics the fastest-growing minority group in the United States after Asians (Humes et al., 2011). It was estimated that the Hispanic population of the United States will grow to 132.8 million or 30% of the nation's population, by 2050 (US Census Bureau, 2015b). The large size of the Hispanic population makes Mexico the only country that has a larger Hispanic population than the United States, and 64.3% of people of Hispanic descent in the United States were from Mexico (US Census Bureau, 2015b). About 76% of Hispanics aged 5 years and older speak Spanish at home, and more than half of these Spanish speakers speak English "very well" (US Census Bureau, 2015b). The poverty rate among Hispanics increased from 23.2% in 2008 to 25.3% in 2009, and the percentage of Hispanics who lacked health insurance also increased from 30.7% in 2008 to 32.4% in 2009. Among the Hispanic population aged 25 years and older, 14% of them had a bachelor's

degree or higher level of education in 2010.

Health Issues of Latino/Hispanic Americans

Hispanic Americans' health is often associated with factors such as language/cultural barriers, lack of access to preventive care, and lack of health insurance. Latino/Hispanic Americans (LHAs) have many health issues complicated by multiple cultural, economic, political, and social factors. Hispanics are the highest uninsured racial or ethnic group in the United States (US Census Bureau, 2015b).

The leading causes of illness and death among Hispanics include heart disease, cancer, HIV/AIDS, stroke, and diabetes. Hispanic men and women have higher incidence and mortality rates for stomach cancer (US Department of Health and Human Services, Centers for Disease Control and Prevention, 2012a). Mexican American adults are almost twice as likely as non-Hispanic whites to have diabetes and 1.5 times as likely to die of this disease (US Department of Health and Human Services, Centers for Disease Control and Prevention, 2012b). Although cardiovascular disease (US Department of Health and Human Services, 2011) and cancer are the first and second leading causes of morbidity and death among LHAs, their incidence in the general population is higher (US Department of Health and Human Services, Centers for Disease Control and Prevention, 2012a). Hispanic women were less likely to have had a mammogram within the past 2 years; however, they were slightly more likely to have had a Papanicolaou test during the past 3 years when compared with non-Hispanic white women (US Department of Health and Human Services, Centers for Disease Control and Prevention, 2012a). In addition, Hispanic adults aged 50 years and older were 34% less likely than non-Hispanic whites to report having undergone colonoscopy, sigmoidoscopy, or proctoscopy (Agency for Healthcare Research and Quality, 2015). Hispanic adults living in the United States generally have lower rates of prostate and breast cancer as compared with non-Hispanic White adults (US Department of Health and Human Services, Centers for Disease Control and Prevention, 2012a).

Some other health conditions and risk factors that significantly

affect Hispanics include asthma, chronic obstructive pulmonary disease, HIV/AIDS, obesity, suicide, and liver disease. LHAs had the second-largest numbers of people with HIV/AIDS in 2014 (Centers for Disease Control and Prevention, 2014).

The difficulties experienced by LHAs in receiving appropriate health care services are comparable to those of the poor and other ethnic minorities. Other barriers include the lack of racial and ethnic diversity in the leadership and workforce of the health care system, lack of interpreter services for Spanish-speaking people, and lack of or inadequate culturally appropriate health care resources. Many Hispanic Americans may not readily seek care because they have continued reliance on their folk system of healing. Their preference for this is logical given their lack of health insurance and perceived difficulties negotiating the health care system because of language and other sociocultural barriers.

Selected Health-Related Cultural Aspects

Each subgroup of the LHA population has distinct cultural beliefs and customs. However, a common heritage determines similar values and beliefs. For instance, the two most important aspects of all Hispanic cultures are the emphasis on the family and the emphasis on religion. For older Hispanic Americans, the family is an important component of good health. The family is the most important source of support; therefore the needs of the family as a whole supersede the needs of the individual. During times of illness and crisis, the family is there for the individual. Older family members and other relatives are accorded courtesy and respect and are often consulted on important matters (Andrews, 2016).

LHAs' dependence on spiritual strength to aid them in illness and dying is evident in their use of prayer. LHAs attribute the origins of disease and illness to spiritual or natural punishments, hot and cold imbalances, magic, dislocation of internal organs, natural diseases, and emotional and mental issues. The **hot and cold concept of disease** was derived from the Hippocratic theory of disease. Illness occurs when there is an imbalance. This concept of hot and cold guides

Hispanics when they categorize illnesses and select appropriate treatments. For example, an elevated body temperature is managed by giving the person a cool drink to lower the temperature. For a person who has a cold, drinking warm fluids would be considered therapeutic (Chong, 2002).

LHAs attribute illness and disease to many supernatural and psychological causes. The evil eye, or the *mal de ojo*, is an example. Fright, or *susto*, and hysteria, or *ataque de nervios*, are caused by strong emotions, crises, and traumatic experiences (Chong, 2002). LHAs still resort to many home remedies and consult folk healers, including the curandero, spiritualist, *yerbero,* and *sabador.* Curanderos use a variety of folk remedies, including prayers, rituals, herbs, and the laying on of hands. Spiritualists use medals, amulets, and prayers to affect a cure. The *yerbero* is knowledgeable in the use of herbs, whereas the *sabador* is an expert in massage and manipulation of bones and muscles (Andrews, 2016). Other Hispanic Americans, such as Cubans, practice *Santeria.* People who are ill may seek the advice of a "godfather" who is a member of the *Santeria.* Wearing white clothes for a year, performing rituals, and following dietary restrictions are involved in bringing forth a cure to an illness (D'Avanzo & Geissler, 2008).

Folk remedies are used in combination with professional care approaches. The individual's belief in the folk remedy can have positive effects on the person's well-being. Therefore professional care personnel need to find ways to blend the two systems to the optimal benefit of LHAs and their families.

Black/African Americans

"Black or African American" (BAA) refers to people having origins in any of the black racial groups of Africa (Humes et al., 2011) and the terms "Black" and "Black or African American" are used interchangeably by the US Census Bureau (2015). According to the 2010 US Census, the 43.1 million people of the BAA population made up 13.6% of the total US population (US Census Bureau, 2016). Black Americans are the second-largest minority population, following the Hispanic/Latino population (US Census Bureau, 2015).

As one of the largest ethnic groups in the United States, BAAs are considered a minority group, a label originating from their slavery roots. Most of the black Americans in the United States are descendants of enslaved people brought from Africa (Waters et al., 2014). Therefore they continue, in many ways, to experience extreme segregation and exclusion from mainstream society, and discrimination by the majority group.

In 2014, most of the black Americans in the United States lived in the Southern states, with the largest black American populations found in the following states: Georgia (33%), Maryland (32%), North Carolina (23%), Virginia (21%), New York (19%), Florida (18%), Illinois (16%), Pennsylvania (13%), Texas (13%), and California (8%) (US Census Bureau, 2014, estimate). BAAs that lived outside the South have a tendency to be more concentrated in metropolitan areas. The places with the largest black American populations were New York, Chicago, and Detroit, with Michigan being the state with the greatest proportion of BAAs (Rastogi et al., 2011).

BAAs have made substantial progress in many areas in the past century. However, there are still inequities in many areas, such as in business, education, political participation, and leadership. The reports of the 2010 US Census indicated that the rate of living at the poverty level for Black Americans was almost three times that for non-Hispanic whites (Office of Minority Health, 2016f). Educationally, BAAs have made substantial gains; 18% of BAAs who were 25 years

or older had a bachelor's degree or a higher degree in 2010 (US Census Bureau, 2016b). The states with the highest BAA educational attainment (a bachelor's degree or higher) include Maryland, Colorado, Oregon, California, Massachusetts, Washington, New Jersey, Arizona, Georgia, and New York, all of which exceed 20%.

Health Issues of Black/African Americans

A complex set of social, economic, and environmental factors can be identified as contributors to the current health status of BAAs. However, poverty may be the most profound and pervasive determinant of health status. Individuals and families who are below the poverty level or lack adequate resources have limited access to health care services such as prenatal and maternal care, childhood immunizations, dental checkups, well-child care, and a wide range of other health-promoting and preventive services. In 2014 the poverty rate in this population was reported as 26.2%, up from 24.7% in 2004; 11.8% of this population was reported as being without health insurance in 2014, down from 15.9% in 2013 (Smith & Medalia, 2015).

Two indices of the effects of poverty can be seen in the high rates of infant mortality and maternal mortality. Despite changes in living conditions, advances in infection control, and improved standards in neonatal care, BAAs still experience high infant and maternal mortality rates. Between 2005 and 2008 the infant mortality rate (number of deaths among infants aged <1 year per 1000 live births) for BAAs was 12.67, which is 2.4 times higher than that of non-Hispanic whites (Centers for Disease Control and Prevention, 2013). BAAs have the second-highest percentage of women who lack prenatal care in the first trimester of pregnancy (Office of Minority Health, 2016g). Black Americans have lower life expectancies than other races at age 65 years. In 2013, life expectancy for black American males (72.3 years) and females (78.4 years) was lower than that for white males (76.7 years) and females (81.4 years) (National Center for Health Statistics, 2015).

Black American children living below the poverty level also experience numerous health problems, including malnutrition,

anemia, and lead poisoning. These problems and the lack of immunizations combine to inhibit normal growth and development and affect school performance. Poverty-stricken families usually live in depressed socioeconomic areas where housing conditions are unsafe and unhygienic. Unsafe buildings and other environmental structures cause accidents and injuries among young children. Young children have fallen to their deaths from windows that were unprotected by metal railings. Older people have suffered falls and other injuries from poorly lit stairways and hallways. Other hazards include uncollected garbage and abandoned buildings that are used as dumpsites or as meeting places for a variety of illegal activities.

Black Americans are affected disproportionately by the leading causes of death in the United States, including cancer, HIV/AIDS, obesity, diabetes, heart disease, and hypertension. The cancer and mortality rates for BAAs are higher than those for white Americans. In 2013 the age-adjusted mortality rate for black Americans was higher than that for whites for heart disease, cerebrovascular disease, malignant neoplasms, influenza and pneumonia, diabetes, HIV, and homicide (National Center for Health Statistics, 2015). Black American women are 40% more likely to die of breast cancer, and they are 2.1 times more likely to die of stomach cancer (Office of Minority Health, 2016h). Although black Americans are only 13% of the US population, they accounted for 47% of HIV/AIDS cases in 2012 (National Center for Health Statistics, 2015). Black American males have eight times the AIDS rate of white males. Black American females have 20 times the AIDS rate of white females (Office of Minority Health, 2016i).

Severe high blood pressure is more common for black Americans in both men and women. Black American adults are 40% more likely to have high blood pressure but 10% less likely to have blood pressure under control than their non-Hispanic white counterparts, and Black Americans are 30% more likely to die of heart disease compared with non-Hispanic white men (Office of Minority Health, 2016j). BAA adults are 60% more likely to have a stroke and males are 60% more likely to die of a stroke (Office of Minority Health, 2016k).

Other health issues including obesity and its contributing factors

are also receiving attention. BAAs are twice as likely as non-Hispanic whites to receive a diagnosis of diabetes, and they are more likely to experience complications from diabetes (Office of Minority Health, 2016l). In addition, individual poverty level and living in a poor neighborhood increased the odds of having diabetes (Gaskin et al., 2014). Higher rate of diabetes may also be related to higher obesity rates among black Americans. BAAs had the greatest prevalence of obesity compared with other races in the United States (Flegal et al., 2012; US Department of Health and Human Services, 2009).

Selected Health-Related Cultural Aspects

Differences in cultural beliefs, attitudes, and practices exist between rural and urban black Americans; however, they share some basic cultural beliefs. Black American culture is centered on the family and religion. The family, the strongest institution, provides strong extended kinship bonds with grandparents, aunts, uncles, and cousins. The family is considered the strongest source of support, especially in times of crisis and illness (Gary et al., 2003). Family members and relatives are consulted before BAAs seek care elsewhere.

Religion and religious behavior are an integral part of the BAA community. The church is a significant support system for many black Americans; it serves many purposes beyond worship and formation, including serving as a place to meet where members can pass on news, take care of business, and find strength of purpose; providing direct social welfare services; acting as a stabilizing force in the community; facilitating citizenship training and community social action; serving as a transmitter of cultural history; providing the means for coping and surviving in a hostile world (McGadney-Douglass, 2000); and counseling and community mental health (Avent et al., 2015; Hankerson et al., 2012; Young et al., 2003).

Africa Americans believe in the healing power of prayer (Vaughn et al., 2009). Black Americans were found to pray more for health reasons (Su & Li, 2011). The BAA church and spirituality play an important role in health issues. For instance, prostate education for

older men is received more favorably when done within the parish nursing approach (Lambert et al., 2002), and religious involvement was found to have a positive effect on health behaviors (Holt et al., 2014).

BAAs define health as a feeling of well-being and the ability to fulfill role expectations. Diseases can be caused by natural or spiritual forces (Ehrmin, 2016); therefore BAAs' approach to health care is guided by these beliefs. Family members, such as grandmothers, and community members are often consulted for traditional home remedies. Traditionally, roots, herbs, potions, oils, powders, rituals, and ceremonies are still used in many Southern communities. The use of healers is also common, including the old lady, who is knowledgeable about folk remedies and child care; the spiritualist, who assists with financial, personal, spiritual, or physical problems; and the voodoo priest or priestess, who is knowledgeable about herbs, signs, and omens (Andrews, 2016).

As noted with the folk health practices of Asian and Hispanic Americans, BAAs' folk healing beliefs and practices can augment the professional care system. Black Americans often find comfort in the support that their religious leader or traditional healer can give them. Health care providers must find an appropriate place for these nontraditional modalities when caring for BAAs.

American Indians/Alaska Natives

American Indian or Alaska Native (AIAN) refers to people who have origins in North America and South America (including Central America) and who maintain tribal affiliation or community attachment (Humes et al., 2011). Native Americans lived in America for thousands of years before the arrival of Europeans. AIANs are the original people of the land now occupied mainly by the Europeans. Evidence shows that AIANs have lived in North America for more than 75,000 years (Josephy, 1991). Native Americans came to be known as Indians, a label given by Columbus when he encountered the native peoples in the West Indies, which he mistook for the East Indies. This label was then extended to all the native peoples of North America and South America, from the Arctic to Tierra del Fuego. Before 1492 there were an estimated 5 million Native Americans. Columbus's discovery brought colonization and settlement by various European groups (Snipp, 2000). Thus the ancestral lands of the Native Americans were usurped, and the people were forced to labor on farms and in mines. Thousands died of disease and hard labor or were killed in attempts to escape from slavery. Other events, such as the removal of the Southeastern tribes in 1830, the Navajos' Long March to Fort Sumner in 1864, and the massacre at Wounded Knee in 1890, caused the Native American population to dwindle to 250,000 by 1890 (Fixico et al., 2001).

In 2010, 5.2 million people in the United States were identified as AIAN (a 26.7% increase since 2000), about 1.7% of the total US population (US Census Bureau, 2014). Between 2000 and 2010 the population of AIANs increased in all 50 states. Native Americans are concentrated in California, Oklahoma, Arizona, Texas, New York, New Mexico, Washington, North Carolina, Florida, and Michigan (Norris et al., 2012). The states with the five highest percentage distributions of AIANs are California (13.9%), Oklahoma (9.2%), Arizona (6.8%), Texas (6.0%), and New York (4.2%). The cities with the highest number of AIANs in 2010, in rank order, were New York,

Los Angeles, Phoenix, Oklahoma City, Anchorage, Tulsa, Albuquerque, Chicago, Houston, and San Antonio. The cities with the highest percentage of AIANs in 2010, in rank order, were Anchorage, Tula, Norma, Oklahoma City, Billings, Albuquerque, Green Bay, Tacoma, Tempe, and Tucson.

Of the total Native American population, 22% live on reservations or other trust lands and about 60% live in metropolitan areas (Office of Minority Health, 2016m). There are 565 federally recognized AIAN tribes and more than 100 state-recognized tribes (Office of Minority Health, 2016m). The Cherokees make up the largest tribe (Ogunwole, 2006).

The Native American percentages for higher education degrees are low in proportion to their total number. Among AIANs who are 25 years or older, 13% obtained a bachelor's degree or higher (US Census Bureau, 2014). Native Americans are making some progress in all levels of college education. However, low continuing educational attainment and low income levels combined with higher rates of poverty are socioeconomic issues that affect the health and the quality of life of this population. Native Americans experience the many negative situations that confront poor people both on the reservations and in the larger society.

Health Care Issues of Native Americans

Many of the health problems of Native Americans can be linked directly to the social and economic conditions described here. These conditions predispose Native Americans to illnesses and health problems that afflict the poor. Some of these problems have been discussed for BAAs. Although Native Americans have responded well to prevention and treatment of infectious diseases, other health problems are closely linked with poverty and harmful lifestyle practices (Office of Minority Health, 2016m).

Cultural barriers, geographical isolation, inadequate sewage disposal, and low income are factors that prevent AIANs from receiving quality medical care. Some of the leading diseases and causes of death among AIANs are heart disease, cancer, unintentional

injuries (accidents), diabetes, and stroke. A study examining trends in cancer mortality and incidence from 1999 to 2009 found less progress in cancer control for AIAN populations compared with white populations (White et al., 2014). American Indians/Alaska Natives also have a high prevalence of and risk factors for mental health and suicide, substance abuse, sudden infant death syndrome, teenage pregnancy, liver disease, and hepatitis (Office of Minority Health, 2016n). A study examining health behaviors and risk factors among AIANs from 2000 to 2010 found a higher prevalence of tobacco use, obesity, and no leisure-time physical activity (Cobb et al., 2014). In addition, AIANs had a lower prevalence of five or more servings per day of fruits and vegetables, cancer screening, and seat belt use.

AIANs have an infant death rate 1.5 times higher than the rate for non-Hispanic white Americans (Office of Minority Health, 2016o). Native American adults are 2.1 times more likely than white adults to have diabetes (Office of Minority Health, 2016p). Wong et al. (2014) found significantly higher infant, neonatal, and postneonatal death rates and average annual death rates for AIANs when compared with whites in almost all of the regions examined. Similar findings were also reported for pediatric death rates. They ranked the leading causes of infant, neonatal, postneonatal, and pediatric deaths, most of which are potentially preventable. AIANs also have disproportionately high rates of death from unintentional injuries and suicide (Office of Minority Health, 2016m).

Many mental health problems also confront Native Americans. Difficult life situations and stresses of daily life contribute to an array of problems, including feelings of hopelessness, desperation, family dissolution, and substance abuse, specifically alcohol. The three most common lifetime diagnoses in the Native American population are alcohol dependence, posttraumatic stress disorder, and major depressive episode (Beals et al., 2005). Native American adults are twice as likely as white adults to have hepatic cancer and more likely to be obese. Their AIDS rates are 40% higher than those of non-Hispanic whites (Centers for Disease Control and Prevention, 2014).

The health problems of Native Americans are complicated by

difficult access to health care. Poor health and limited health care options among urban AIAN populations have been well documented in many studies. Since 1972, the Indian Health Service (IHS), a government agency in the US Department of Health and Human Services, has stated a series of initiatives to fund health-related activities in off-reservation settings that make health care services accessible to urban AIANs. Federally recognized tribes are provided with health and educational assistance through the IHS (Office of Minority Health, 2016m). Approximately 1.9 million AIANs receive a health service delivery system operated by the IHS. About 36% of the IHS service area population resides in non-Indian areas, and 600,000 are served in urban clinics (Office of Minority Health, 2016m). Even though the IHS attempts to provide comprehensive, high-quality health care services to AIANs, the quality of care and access to health services need to be improved.

Selected Health-Related Cultural Aspects

Native Americans are generally present oriented: they emphasize events that are occurring now rather than events that will happen later. They take one day at a time, and in times of illness they cope by hoping for improvements the next day (Ehrmin, 2016). Native Americans also value cooperation rather than competition. Sharing of resources, even among the poor, is an important component of this cultural value. Family and spiritual beliefs are important for Native Americans. Native Americans place great value on their families and relatives. Three or more generations form an extended kinship system, which is enlarged by the membership of nonrelatives, who are included through various religious ceremonies (Boyle, 2016).

Despite the great diversity in Native American groups in their beliefs and practices concerning health, illness, and healing, they share a common philosophical base. Native Americans believe that optimal health exists only when a person lives in a condition with balance and harmony in the inner and outer domains of life (Grandbois, 2005). The Earth is seen as a living entity that should be treated with respect; failure to do so harms the body. Instead of viewing illness as changes

in a person's physiological state, Native Americans view it as an imbalance between the person and natural forces (Boyle, 2016; Grandbois, 2005). Native Americans believe that a person's sickness can be traced directly to that person having committed a violation against natural and spiritual laws; an individual can also inherit such a violation. The violation causes the person to have an imbalance that causes illnesses mentally, physically, emotionally, and spiritually.

Many AIANs proudly express spirituality, traditional medicinal practices, and cultural ceremonies in their lives. AIANs frequently seek traditional practitioners, who are medicine women or men known as shamans and are believed to have hypnotic powers, the gift of mind-reading, and expertise in concocting drugs, medicine, and poisons, and who carry out rituals and healing ceremonies that are believed to restore the sense of balance, harmony, and unity that the acute or traumatic event has caused (Grandbois, 2005).

The Emerging Rural and Urban Populations: Homeless Persons

Homelessness: A Continuing Saga

Homelessness is a complex social and economic problem that continues to persist and grow. Many services and programs have been developed to address the issue, yet homelessness remains a significant problem. Homelessness could be defined as a lack of fixed, regular, and adequate nighttime residence resulting from extreme poverty and/or unsafe or unstable living environments (National Alliance to End Homelessness, 2012a; National Association for the Education of Homeless Children and Youth, 2016; National Coalition for the Homeless, 2009). In many studies, homeless people were counted as individuals who are in shelters or on the streets (National Coalition for the Homeless, 2009). However, homelessness is considered a temporary situation, not a permanent condition. Instead of the number of "homeless people," it has been suggested that the number of "people who experience homelessness over time" is a more appropriate measure of the magnitude of homelessness (National Coalition for the Homeless, 2009). Fortunately, homelessness declined by 9% and long-term homelessness declined by 7% from 2007 to 2013 (Henry et al., 2013).

It was estimated that about 3.5 million people (1.35 million of them children) are likely to experience homelessness in a given year (National Coalition for the Homeless, 2009). On a given night in January of 2013, 610,042 people were homeless, of which 23% were children younger than 18 years, 10% were aged 18 to 24 years, and 67% were 25 years or older (Henry et al., 2013). It was estimated that 42% of the homeless population are Black American, 39% are white, 13% are Hispanic, 4% are Native American, and 2% are Asian (National Coalition for the Homeless, 2009). The following five states account for more than half of the homeless population: California (22%), New York (13%), Florida (8%), Texas (5%), and Massachusetts

(3%) (Henry et al., 2013). Between 2007 and 2013, New York, Massachusetts, Missouri, District of Columbia, and Ohio had the largest increases in the number of homeless people (Henry et al., 2013). During the same time period, California, Michigan, Texas, Washington, and New Jersey had the largest decreases in the number of homeless people.

Why Families and People Become Homeless

Both structural and personal factors alone or in combination lead to lack of resources to secure and/or maintain housing. An increasing shortage of affordable rental housing and a simultaneous raise in poverty are two trends largely responsible for the growth of homelessness in the past 20 to 25 years (National Coalition for the Homeless, 2009a). Between 2005 and 2007, the number of repeated homeless individuals in the United States declined by 28% because of an increase in permanent supportive housing in the country. Recently, foreclosure has been a factor closely related to the increased number of people who experience homelessness in the United States (National Coalition for the Homeless, 2009b). Factors such as poverty, eroding work opportunities, a decline in public assistance, and lack of affordable housing are also significantly contributing to homelessness (National Coalition for the Homeless, 2009b) (Figure 2-2). Within the context of poverty and the lack of affordable housing, other additional major factors, such as lack of affordable health care, domestic violence, mental illness, and addiction disorders, can also contribute to homelessness (National Coalition for the Homeless, 2009b). In a study by Thompson et al. (2013), poverty, alcohol-use disorder (only), drug-use disorder (only), and both alcohol-use disorder and drug-use disorder were all significant predictors of first-time homelessness. In a systematic review of risk factors for homelessness among US veterans, substance abuse and mental illness were the two strongest and most consistent risk factors, followed by income-related factors (Tsai & Rosenheck, 2015).

FIGURE 2-2 A homeless man works at a day labor job to earn some money.

Health Issues of Homeless People and Families

Poor health is both an effect and a cause of homelessness. Homelessness and health care are closely interlinked. A serious health problem could force a person who does not have adequate health insurance to choose between paying bills for health care or paying rent for a place to live. The National Health Care for the Homeless Council (NHCHC) reported that half of all personal bankruptcies in the United States are caused by health problems (National Coalition for the Homeless, 2009c).

Homelessness is associated with various behavioral, social, and environmental risks that expose individuals to many diseases. People experiencing homelessness usually have complex health problems. The lives of homeless persons and families are constant battles for daily survival. Homeless persons experience exposure to extremes in temperatures, unsanitary living conditions, crowded shelters, poor nutrition, and unsafe situations, wherever they live. They experience the same situations relative to health care; poor access because of lack of health insurance and inadequate resources to travel to health facilities.

As a result of poor living conditions and limited access to health

care, homeless people are at a higher risk of being exposed to disease, violence, unsanitary conditions, malnutrition, stress, and addictive substances. The rates of serious illnesses and injuries among homeless people are three to six times the rates seen among the rest of the population (NHCHC, 2016a). This complex mixture of severe physical and/or psychiatric illness, substance abuse, and social problems is frequently found in homeless people (NHCHC, 2016b). Many diseases, including heart disease, cancer, liver disease, kidney disease, skin infections, HIV/AIDS, pneumonia, and tuberculosis, are common among the homeless population (National Coalition for the Homeless, 2009c). Compared with housed respondents, homeless patients were significantly more likely to be substance abusers (e.g., current smoker, binge drinking, high risk of alcohol and drug dependence, and any injection drug use), have a worse health status, experience food insufficiency, have chronic conditions (e.g., obstructive lung disease, liver and kidney conditions), experience two or more chronic conditions, and have mental health issues (e.g., psychological distress, depression, anxiety, panic disorder) (Lebrun-Harris et al., 2013). In addition, homeless patients surveyed were twice as likely to have unmet medical care needs and twice as likely to have visited the emergency department in the past year compared with housed respondents.

HIV/AIDS and homelessness are intricately associated. The homeless population has a higher prevalence of HIV/AIDS infections than the general population in the United States. It was estimated that 3.4% of homeless people were HIV positive in 2006, compared with 0.4% of adults and youths in the general population (National Coalition for the Homeless, 2009d). The conditions of homelessness may increase an individual's risk of becoming infected with HIV. Having substance abuse disorders and sharing or reusing needles to intravenously inject drugs greatly increases homeless peoples' risks of being infected with HIV. The homeless environment (such as limited privacy and communal sleeping and bathing at shelters) is not conducive to stable sexual relationships and makes it more likely for the homeless person to engage in risky sexual behaviors, therefore

increasing the likelihood of contracting HIV (National Coalition for the Homeless, 2009d). Psychosocial distresses are not only associated with many mental health problems in homeless people but also influence behaviors that could affect the progression of HIV/AIDS (National Coalition for the Homeless, 2009d). Limited access to medical care severely prevents homeless people from receiving adequate HIV/AIDS treatment as well as education concerning HIV/AIDS prevention and risk reduction (National Coalition for the Homeless, 2009d). The homeless condition may also make adherence to HIV treatment regimens challenging for homeless patients and their caregivers (National Coalition for the Homeless, 2009d). In a study of HIV-infected drug users, homelessness and frequent heroin use were negatively associated with antiretroviral therapy adherence (Palepu et al., 2011). In addition, methadone maintenance was positively associated with antiretroviral therapy adherences, which speaks of the importance of improving housing status and methadone maintenance to increase adherence and thus survival in this population. To provide comprehensive services such as health education, HIV testing, case management, and mental health services, basic health care is needed for homeless people with HIV/AIDS.

Stress, depression, and other mental health problems are also common in homeless people. People who are homeless experience extreme stress on a daily basis. Multiple stresses of living in shelters and on the streets, physical problems, lack of resources, psychosocial issues such as shame and stigma, and feelings of hopelessness and despair often tax the homeless person's ability to cope. The homeless are also more likely to have gambling disorders (Shaffer et al., 2002). About half of people experiencing homelessness have mental health issues. Although only 6% of the general American population are severely mentally ill, about 25% of homeless people in the United States have serious mental illness, including chronic depression, bipolar disorder, and schizophrenia (National Alliance to End Homelessness, 2012b; National Coalition for the Homeless, 2009e). Homeless people are also more likely to have cognitive impairment (Depp et al., 2015), which further complicates their mental health.

The prevalence of substance abuse among homeless people is much higher than that among the general population (National Coalition for the Homeless, 2009f). It is estimated that more than half of all people experiencing homelessness have substance abuse disorders (United States Interagency Council on Homelessness, 2016). Substance abuse is both a leading cause and a consequence of the continuance of homelessness among individuals. Substance abuse was reported as the single major cause of homelessness for single adults and as one of the top three causes of homelessness for families, and more than half of homeless people reported that drugs and/or alcohol was a major cause of their homelessness (National Coalition for the Homeless, 2009f). Substance abuse also often arises after individuals become homeless. Homeless people abuse substances in an attempt to obtain temporary relief from their problems and eventually rely on drugs and alcohol to cope with their daily struggles; however, the substance dependence only worsens their problems and makes it more difficult for them to escape their homeless status (National Coalition for the Homeless, 2009f). Substance abuse and drug abuse often co-occur with mental health problems among homeless people (Polcin, 2015). It is estimated that almost half of all persons experiencing homelessness have substance abuse disorders, and most of the homeless individuals with substance abuse disorders also have moderate to severe mental illness (United States Interagency Council on Homelessness, 2016). A survey of homeless youth found that 22% reported current prescription drug misuse and 13% were currently injecting drugs (Al-Tayyib et al., 2014). Furthermore, those that reported prescription drug misuse in the prior 30 days were significantly more likely to also have injected drugs during that same period.

Most homeless people do not have health insurance or the ability to pay for needed health care, and many providers refuse to treat homeless people (NHCHC, 2016a). Even though federally funded health care services provide primary care for homeless people, the homeless individuals who are able to benefit from these services are far fewer than those who desperately need care (NHCHC, 2016b). Several barriers that prevent access to health care have been

recognized. These barriers include lack of knowledge regarding where to receive treatment, lack of access to transportation, and lack of identification (National Coalition for the Homeless, 2009c). Widespread access to affordable, high-quality, and comprehensive health care is necessary to stop homelessness (National Coalition for the Homeless, 2009c). On March 23, 2010, President Obama signed the Affordable Care Act into law, establishing new directives to improve access to affordable health coverage for all Americans and to protect Americans from obnoxious practices of insurance companies (USDHHS, 2016). The law gives all Americans access to care by their choosing affordable health insurance that fits their needs; this law also attempts to control health care costs without jeopardizing the quality of care (US Department of Health and Human Services, Center for Disease Control and Prevention, 2012).

Strategies to Address Homelessness

Homelessness has long been recognized as a multidimensional problem of modern-day society. The homeless situation is a problem not only of individuals but also of families, communities, and societies. This problem needs to be addressed as a dynamic and not a static phenomenon, because as societies continue to change and evolve, there will always be those who are excluded and suffer consequences. These are the risks that must be actively anticipated so that strategic planning can forestall any devastating and long-lasting effects.

Many initiatives to address the issues of homeless people are being implemented by the NHCHC, which works with people who have experienced homelessness, health care and service providers, and policymakers; provides advocacy, research, and training; and collaborates clinical resources to break the connection between poor health and homelessness (NHCHC, 2016b). For more information about services and projects initiated by the NHCHC or its partners, visit http://www.nhchc.org.

Resolving health problems and resolving homelessness are dependently interrelated. Many health problems are highly prevalent

in people experiencing homelessness. Health conditions such as diabetes, HIV/AIDS, addiction, and mental illness require ongoing treatment. If people do not have a stable place to stay, treating their health conditions and their finding time for healing and recovery from health problems are almost impossible. Preventive care can also be difficult for homeless people to access because it is often unaffordable (National Alliance to End Homelessness, 2012a). To end homelessness, mental and physical health conditions should be considered when effective, efficient strategies are being designed, and permanent stable housing together with supportive services is needed (National Alliance to End Homelessness, 2012b; NHCHC, 2016a). Fitzpatrick-Lewis et al. (2011) summarize recommendations for interventions for the homeless with concurrent mental illness and who are substance abuser and for the homeless with HIV. The Health Care for the Homeless Clinicians' Network has created clinical practice guidelines for the care of homeless patients. The recommended guidelines are available at http://www.nhchc.org/wp-content/uploads/2011/09/General-Recommendations-for-Homeless-Patients.pdf.

Research and practice have shown that permanent supportive housing works because housing is an essential part of treatment (National Coalition for the Homeless, 2009b). In addition to providing permanent supportive housing, strategies to assist homeless persons also include helping them gain access to the health care system and benefits, working with the community to obtain services and resources, educating homeless persons about their health, and educating health care personnel about homeless persons. Communities need to continue their in-kind work with homeless persons. Many schools and houses of religious worship have worked with local governments in extending support to the homeless. Food, clothing, night shelter, and short-term socializing have been provided. Parishioners may donate their time preparing meals, preparing the shelter, and serving as chaperones during the night. Much work is still needed to reduce homelessness. The needs of the recently identified rural homeless must be addressed. Every citizen should be educated

so each person can serve as an advocate, and neighborhood coalitions should be established to prevent an increase in the number of homeless persons and to support the return of the homeless person as a dignified, contributing member of society. Health care providers must continue to seek effective ways to coordinate their efforts through the creation of comprehensive resource materials. Technology must be used at its maximal capability to facilitate assessment and monitoring. Preparation for health care for the homeless in both rural and urban settings should be strengthened as an essential part of the curriculums of the health care disciplines. Finally, more research regarding health care outcomes should be supported and data should be disseminated in a timely manner.

There is a greater degree of optimism today in dealing with the problems of homelessness. Individuals and communities are showing concern through increased involvement. Homelessness is everyone's problem, and people can ultimately effect the establishment of priorities to facilitate an improved quality of life. Increasing awareness and knowledge of the current status of homeless people will aid in understanding the problem and its ramifications. This understanding will serve as an excellent guide in providing input, taking necessary action, and making the final decision regarding the changes needed to make a healthy nation.

Health care professionals play a significant role in helping homeless persons. It is important for them to be capable of meeting the complex health needs of homeless people. Creative care planning is necessary for the homeless patient because standards of care may not be suitable for an individual who experiences homelessness and does not have a home where the basic requirements for self-care and recovery are available (Billings & Kowalski, 2008). Community health practitioners are also at the forefront of advocacy for the homeless as they work to effect changes and develop strategies to deal with the problems associated with the health status of homeless people.

The Nation's Response to the Health Challenge

The National Institutes of Health has proclaimed health disparities as a major concern. It is putting significant effort into addressing and reducing health disparities involving cancer, diabetes, infant mortality, AIDS, cardiovascular illnesses, and many other diseases (Office of Minority Health, 2016a). In 2010 the US Congress stressed its commitment to health equity by elevating the National Center on Minority Health and Health Disparities to the National Institute on Minority Health and Health Disparities. In 2011 the US Department of Health and Human Services released two plans (The National Stakeholder Strategy for Achieving Health Equity and the HHS Action Plan to Reduce Racial and Ethnic Health Disparities) to reduce health disparities (Hansen, 2011). For more information regarding the two plans and the National Conference of State Legislatures, visit http://www.ncsl.org/.

Healthy People 2020

Healthy People 2020 outlines a comprehensive, nationwide health-promotion and disease-prevention agenda. This initiative is designed to serve as a road map for addressing and improving the health of all people in the United States. In the past 2 decades, one of Healthy People's primary goals has concentrated on disparities. In *Healthy People 2010,* the primary focus was not just as in *Healthy People 2000* to reduce health disparities among Americans, but also to eliminate health disparities. In *Healthy People 2020,* the goal has been expanded further: to achieve health equity, eliminate disparities, and improve the health of all groups (US Department of Health and Human Services, 2010). For more information about topics and objectives in *Healthy People 2020,* visit http://www.healthypeople.gov/.

Office of Minority Health

The Office of Minority Health was created in 1986, and it was reauthorized by the Patient Protection and Affordable Care Act of 2010 (Office of Minority Health, 2016a). The Office of Minority Health has been working for more than 20 years to improve and protect the health of racial and ethnic minority populations through the development of health policies and programs that concentrate on eliminating health disparities. The Office of Minority Health is leading the charge to put into practice the HHS Action Plan to Reduce Racial and Ethnic Health Disparities at all levels of the Department of Health and Human Services and in the communities with whom it works.

In recent years, the Office of Minority Health started two initiatives (the National Partnership for Action to End Health Disparities and the Strategic Framework for Improving Racial and Ethnic Minority Health and Eliminating Racial and Ethnic Health Disparities) to guide its efforts toward eliminating health disparities in the United States. Both initiatives implemented a coordinated, systems-level approach that focused on eliminating health disparities and was contingent on science and knowledge to notify and continually improve policies and programs. The goals of the National Partnership for Action to End Health Disparities are to enhance awareness of the importance of health disparities and actions needed to improve health outcomes for racial and ethnic minority populations, strengthen and expand leadership for dealing with health disparities at all levels, improve health and health care outcomes for racial and ethnic minorities and underserved populations and communities, improve cultural and linguistic competency in delivering health services, and improve coordination and utilization of research and evaluation outcomes. The main purpose of the Strategic Framework for Improving Racial and Ethnic Minority Health and Eliminating Racial and Ethnic Health Disparities is to direct, organize, and coordinate the systematic planning, implementation, and evaluation of efforts that are targeted at improving racial and ethnic minority health and addressing racial and ethnic health disparities. For more information about trends in US public awareness of racial and ethnic health disparities, visit http://minorityhealth.hhs.gov/assets/pdf/checked/1/2010StudyBrief.pd

Another initiative established by the Centers for Disease Control and Prevention is the Racial and Ethnic Approaches to Community Health, established in 2010. Its objective is to "eliminate disparities in health access and outcomes. These six health areas were selected for emphasis because they reflect areas of disparity that are known to affect multiple racial and ethnic minority groups at all life stages" (Office of Minority Health, 2016a). These areas include infant mortality; deficits in breast and cervical health promotion and disease prevention; and child and adult immunizations.

There are also minority health research initiatives sponsored by the National Institutes of Health, Centers for Disease Control and Prevention, and the Agency for Healthcare Research and Quality. Support for these initiatives and future ones must continue at all levels.

Nursing's Response to Emerging Populations and Health

The *Code of Ethics for Nurses* of the American Nurses Association (ANA) explicitly states the profession's commitment to provide service to people regardless of background or situation (ANA, 2016). Nurses have responsibilities to be aware of specific health needs and respond to illness in all populations. The ANA's Council on Cultural Diversity supports the work of nurses in their development of culturally competent care. The organization and its leadership, through the Ethnic-Minority Fellowship Program, have played an essential role in supporting the work and efforts of AAPIs, BAAs, LHAs, and Native Americans with graduate and doctoral work. Nurses continue to make many positive moves toward understanding culturally diverse populations. See the case study and care plan regarding Mr. and Mrs. Arahan, an older adult immigrant couple, at the end of this chapter, which propose nursing interventions to ensure their quality of life in their later years. Nurses' awareness and understanding of transcultural issues have been facilitated by the works of leaders such as Leininger, Giger, Davidhizar, Andrews, and Boyle, to name just a few. In addition, wide dissemination of research findings has been made possible through the *Journal of Transcultural Nursing* and through annual conferences and other sponsored workshops. Additionally, nurses with advanced preparation have committed their time and energy to developing approaches and models for **transcultural nursing.**

Several nursing journals focus on cultural diversity, such as the *Journal of Cultural Diversity* and the *Journal of Multicultural Nursing and Health.* These journals and a variety of other publications are constantly increasing professionals' knowledge of health-related cultural issues. In addition, the *Minority Nurse Newsletter* provides excellent summaries of research studies, legislative updates affecting ethnic minorities, and relevant topics in education and practice. Ethnic

nursing organizations are having an effect on greater cultural understanding through their dissemination of important works by clinicians, educators, and researchers (Box 2-5: Innovative Practice).

Box 2-5

Innovative Practice

Spiritual Practices and Health

Spirituality and its relationship with health outcomes have been the focus of considerable interest in recent years (Como, 2007). Spirituality can be defined as an individual's sense of peace, purpose, and connection to others as well as the person's beliefs about the meaning of life. Many people believe that spirituality plays an important role in their lives (Gillum & Griffith, 2010; National Cancer Institute, 2012).

A growing amount of evidence reveals that spirituality and spiritual care play an important role in health and health care (Ehrlich, 2011). Considerable evidence has shown spiritual practices as an important and effective coping strategy and a common approach to dealing with health problems, particularly chronic diseases such as cardiovascular disease and cancer (Como, 2007; Medical University of South Carolina, 2012; National Cancer Institute, 2012). Spiritual practices are likely to improve coping skills and social support, promote feelings of optimism and hope, encourage healthy behavior, decrease feelings of depression and anxiety, and support a sense of relaxation (National Cancer Institute, 2012). Many studies have found that spiritual or religious beliefs and practices help patients with cancer as well as their caregivers to cope with the disease (National Cancer Institute, 2012). Studies also suggest that many patients would like health care providers to consider spirituality as a factor in their health care. It was reported that 94% of people admitted to the hospital agree that spiritual health is as important as physical health, and some studies show that health care providers' support of spiritual well-being helps improve patients'

quality of life (National Cancer Institute, 2012).

A spiritual assessment may help health care providers understand how religious or spiritual beliefs will affect the way a patient copes with diseases and health problems. Few tools for assessing spiritual history and/or spiritual practices have been developed to help health care professionals consider patients' spiritual needs and/or plan appropriate spiritual interventions for their patients. A spiritual practices checklist (Quinn-Griffin et al., 2008) was developed to identify the religious or spiritual interventions used and the frequency of use of religious or spiritual interventions. The 12 items of the checklist include the most commonly used spiritual practices (e.g., prayer) and CAM interventions (e.g., meditation, yoga). Other examples of tools are the FAITH, the HOPE, and the FICA tools that help physicians assess patients' history of spirituality (Medical University of South Carolina, 2012). More information about the HOPE tool can be found at http://www.aafp.org/afp/2001/0101/p81.html?printable=afp.

It has been suggested by The Joint Commission that a spiritual assessment should be performed on every patient to identify patient's values, beliefs, and spiritual practices (Wesa & Culliton, 2004). Each person may have different spiritual needs, depending on cultural and religious traditions. For example, black Americans and Hispanic Americans were found to be more likely than European Americans to report prayer for health reasons (Gillum & Griffith, 2010). To better counsel and care for patients, health care providers should be aware of the common ethnic patients who may have more and special spiritual and religious needs and the common spiritual practices used by patients.

Major organizations such as the ANA, the National League for Nursing (Winland-Brown et al., 2015) publish culturally relevant materials to guide students, clinicians, and educators. Accrediting bodies for nursing education such as the Commission for Nursing Education Accreditation and the Commission on Collegiate Nursing Education support diversity with the inclusion of standards for maximizing diversity in the academic preparation of students pursuing bachelor's and master's degrees. Additionally, there is a cadre of nurses whose research on the cultural practices and beliefs of individuals and families gives professionals a sound base for improving practice and designing cost-effective and humanistic health care strategies. The quest to deliver culturally competent care has provided the impetus for nursing faculty to require transcultural courses in the nursing curriculum to facilitate awareness and understanding of cultural diversity. Transcultural nursing is an area of nursing study and practice that focuses on discovering and explaining cultural factors that influence the health, well-being, illness, or death of individuals or groups and seeks to provide culturally based appropriate care to people of diverse cultures (Leininger, 2001). Culture care diversity and universality theory (Leininger, 2002), developed by Madeleine Leininger, is a well-recognized theory used globally by many nurses, and it has significantly contributed to the establishment and advancement of transcultural nursing research knowledge and practice. It is essential for nurses to plan culturally tailored and competent care to mitigate health disparities and provide effective care in our rapidly changing multicultural societies, thereby delivering quality and safe care to all (Box 2-6: Quality and Safety Scenario).

Box 2-6

Quality and Safety Scenario

Immigrants and Health Care Providers

Mr. Jade and Madam Nora have four children: Nirman (6 months), Julia (18 months), Hady (4 years), and Jamella (6 years). Mr. Jade is an economist who immigrated to the United States from Iraq 4 years ago. The family has come to the well-baby clinic because Madam Nora has been concerned about Nirman; Nirman's skin appears paler than that of her siblings, and she is also not gaining weight. Mr. Jade gave a brief health history of Nirman's situation because his wife cannot express herself in English. “My wife believes that Nirman is not growing like the rest of our children. She breastfeeds her every 2 hours, but she is not eating.” My wife is “upset that Nirman is not becoming bigger.” The vital signs are as follows: pulse, 125 beats per minute; respirations, 22 breaths per minute; blood pressure, 100/70 mmHg; and rectal temperature, 99.4° F. Nirman's weight is 10 lb, 0 oz, and her length is 22 inches. Nirman appears pale. Madam Nora, aged 28 years, is wearing a headscarf covering her hair and a long dress. When Mr. Jade and Madam Nora are left alone, nurses can hear them arguing and raising their voices in a foreign language (Arabic), and Madam Nora appeared very upset. The medical history revealed a term baby female born by normal vaginal delivery with a normal birth weight. No history of vomiting, diarrhea, or fever was reported. Pallor and jaundice were noted on physical examination. The family history revealed that both Mr. Jade and Madam Nora came from the same village and are Muslim and second-degree cousins. No genetic studies have been performed for the family members. Nirman's initial diagnosis is hemolytic anemia.

Nurses should consider the unique cultural background and family dynamics and functioning while providing care to this immigrant family to ensure safe and quality care. The family has an ineffective communication pattern and an inability to navigate through the complexity of the health care system. Madam Nora needs to communicate with health care providers through her husband, who,

in turn, is not familiar with medical terminology. The fact that no genetic testing was performed among family members may be attributed to the unfamiliarity and complexity of the health care system in the United States as compared with the health services in their native country. It is important for nurses to have culturally competent skills and to identify cultural beliefs that may impact how immigrant patients may communicate with them. Hence effective approaches may be implemented to provide safe and quality care for this population and to mitigate health disparities.

Additionally, major textbooks focusing on specific clinical areas of practice devote material to health care issues of ethnic minorities. Other resources include a chapter or two on cultural diversity. In addition, discussion of specific health care problems and nursing care always includes cultural aspects. In the clinical setting, health care workers, through staff development and in-service programs, are provided with opportunities to learn and develop culturally sensitive care approaches.

Case Study

An Older Immigrant Couple: Mr. and Mrs. Arahan

Mr. and Mrs. Arahan, an older couple in their 70s, have been living with their oldest daughter, her husband of 15 years, and their two children, aged 12 and 14 years. They all live in a middle-income neighborhood in a suburb of a metropolitan city. Mr. and Mrs. Arahan are both college educated and worked full-time while they were in their native country. In addition, Mr. Arahan, the only offspring of wealthy parents, inherited a substantial amount of money and real estate. Their daughter came to the United States as a registered nurse and met her husband, a drug company representative. The older couple moved to the United States when their daughter became a US citizen and petitioned for them as immigrants. Because the couple were facing retirement, they

welcomed the opportunity to come to the United States.

The Arahans found life in the United States different from that in their home country, but their adjustment was not as difficult because both were healthy and spoke English fluently. Most of their time was spent taking care of their two grandchildren and the house. As the grandchildren grew older, the older couple found that they had more spare time. The daughter and her husband advanced in their careers and spent a great deal more time at their jobs. There were few family dinners during the week. On weekends, the daughter, her husband, and their children socialized with their own friends. The couple began to feel isolated and longed for a more active life.

Mr. and Mrs. Arahan began to think that perhaps they should return to their home country, where they still had relatives and friends. However, political and economic issues would have made it difficult for them to live there. Besides, they had become accustomed to the way of life in the United States with all the modern conveniences and abundance of goods that were difficult to obtain in their country. However, they also became concerned that they might not be able to tolerate the winter months and that minor health problems might worsen as they aged. They wondered who would take care of them if they became very frail and where they would live, knowing that their daughter had saved money only for their grandchildren's college education. They expressed their sentiments to their daughter, who became very concerned about how her parents were feeling.

This older couple had been attending church on a regular basis but had never been active in other church-related activities. The church bulletin announced the establishment of parish nursing with two retired registered nurses as volunteers. The couple attended the first opening of the parish clinic. Here, they met one of the registered nurses, who had a short discussion with them about the services offered. The registered nurse had spent a great deal of her working years as a community health nurse. She informed Mr. and Mrs. Arahan of her availability to help them resolve any health-related issues.

Reflective Questions:

- What strategies could be suggested for this older adult couple to enhance their quality of life?
- What community resources can they use?
- What can the daughter and her family do to address the feelings of isolation of the older couple?
- What health-promotion activities can ensure a healthy lifestyle for them?

Care Plan

An Older Immigrant Couple: Mr. and Mrs. Arahan

***NURSING DIAGNOSIS: Risk of continued feelings of isolation**

Defining Characteristics

- The couple no longer have a great deal of caretaking responsibilities.
- The daughter and her husband spend a great deal of time on their careers.
- Family dinners during the week are seldom.
- The daughter and her family socialize with their own friends.
- The older couple is thinking of returning to their native country.
- The couple is concerned about life in the United States with harsh winters and their minor health problems.
- The couple is concerned about their advancing years and future living arrangements.

Related Factors

- Transition from the native country to the United States.
- Differing religious, ethnic, and cultural backgrounds between the native country and the United States influence care decisions.
- Differing roles in family structures between the native country and the United States.
- Conflicting roles between the two generations.
- Limited opportunities for social support and assimilation for older immigrants to the United States.
- Health and health care needs, multiple and complex, for the elder population in the United States.

Expected Outcomes

The Arahans will:

- Join a senior citizen center for socialization and other activities.
- Volunteer at a nearby hospital or school several mornings or afternoons per week.
- Work with their daughter and her family to plan at least one family meal per week.
- Pursue some neglected hobbies.
- Get involved in a church group or in a civic organization.
- Begin a discussion on future alternate living arrangements.
- Make periodic visits to the native country to see relatives and friends.

Interventions

- Encourage the couple to have open discussions about their concerns with their daughter and her family.
- Support them in their choice of meaningful activities such as joining the senior center and volunteering.
- Provide information on resources for future living arrangements in the United States.
- Develop a plan for health monitoring on a regular basis.
- Provide a list of organizations that address issues and concerns of older adults such as the American Association of Retired Persons (AARP).
- Utilize their experience and expertise (if any) in managing the parish nursing clinic.
- Initiate an older support group in the parish with the Arahans as the first members.

The Arahans' situation is a very common one in most immigrant groups. The interventions outlined would need to consider the cultural traditions, personal preferences, health status, motivation level, physical ability, and resources of the couple to ensure positive outcomes and goal achievement.

*NANDA Nursing Diagnoses—Herdman T.H. & Kamitsuru, S. (Eds.). Nursing Diagnoses - Definitions and Classification 2015-2017. Copyright © 2014, 1994-2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

This century will continue to be a time of great challenges as the population of the United States continues to be a nation of diverse peoples. The nation and its people have repeatedly overcome devastations by both nature and humankind itself. As citizens, emerging populations share similar concerns about life, including health, an acceptable standard of living, and quality of life. An array of cultural, economic, educational, social, and political barriers are being eroded at the local, national, and global levels to ensure the health and well-being of the people of the United States. The government, public and private industries, health care professions, and all individuals can work together to reduce health disparities and ensure a healthy nation for future generations.

Health Policy and the Delivery System

Debora Elizabeth Kirsch

OBJECTIVES

After completing this chapter, the reader will be able to:

- Examine key developments in the history of health care that influenced the philosophical basis of American health care and separated preventive measures from curative measures.
- Differentiate between private and public sector functions and responsibilities in the delivery of health care.
- Describe the mechanisms by which health care in the United States is financed in both the private sector and the public sectors.
- Analyze the influence of health legislation on the health care delivery system.
- Differentiate between the purposes, benefits, and limitations of Medicare, Medicaid, and other government-sponsored programs in achieving health equity.
- Compare and contrast the health care delivery systems of the United States and other countries.
- Discuss the major provisions of the Patient Protection and Affordable Care Act of 2010 and its impact on improving population health.

KEY TERMS

Accountable care organizations (ACOs)
Advanced practice nurses (APNs)
Advocate
Affordable Care Act (ACA)
Concierge care
Fee-for-service
Gatekeeper
Health insurance exchange
Health maintenance organizations (HMOs)
Health savings accounts (HSAs)
High-deductible health insurance plans (HDHPs)
Hospitalist
Indemnity insurance plans
Independent practice associations (IPAs)
Insurance
Managed care
Marketplace
Medicaid
Medicare
Nursing centers
Point-of-service (POS)
Preferred provider organizations (PPOs)
Primary care provider (PCP)

Think About It

The Federal Health Care Reform Law

The passage of the health care federal reform law called the Patient

Protection and Affordable Care Act ignited the national conversation on the expanding role of government in health care. Within the many provisions of the law, a federal government mandate now requires most American citizens to have health insurance coverage or face financial penalties. Although health insurance coverage is an essential element in promoting the health of an individual, questions remain on how best to serve the health care needs of all Americans.

- Will the provisions of the law solve the problems of access to affordable quality health care for all citizens?
- With a greater proportion of the population now mandated to have health insurance, will the overall health of the population be improved?
- How will the law curtail rising health care costs and issues of quality and safety?
- Why is the American health care system the most costly in the world?

The health care delivery system in the United States is a complex, multilayered entity that has the capacity to provide the newest technological treatments and implement the most advanced health care in the world. Research findings have sparked the development of international gold standards for practicing evidence-based medical and nursing care. The market-driven, multipayer, heavily private system is distinct from any other health care delivery system in the world, employing almost 12 million health care workers, practitioners, and health care support occupation workers in 2014, to serve more than 322 million people. The US Bureau of Labor Statistics reports the projection of 14 of the 20 fastest growing occupations between 2012 and 2022 are health care related (US Department of Labor, 2014). Of the 800 occupations the Bureau of Labor Statistics reports on, registered nurses constitute the largest number of professionals, with more than 2.7 million jobs, with an above-average salary of $69,790. A

projected growth of more than 526,000 registered nurse jobs over the 2012 to 2022 period is predicted because of an increased emphasis on preventable care, the aging baby boomer population, and increased rates of diabetes, obesity, and other chronic conditions (US Department of Labor, 2015a,b). The American health care system is massive but so is the cost. The rising cost of health care is consuming a growing percentage of the nation's gross domestic product (GDP). The Centers for Medicare & Medicaid Services (CMS) reported in 2014 that national health expenditures consumed 17.4% of the nation's GDP (i.e., more than $3.0 trillion), which equates to $9255 per person, the highest dollar amount per capita of all industrialized countries. Projected health spending for 2014 to 2024 is expected to grow at 5.8% per year, resulting in a rise to 19.6% in the nation's GDP by 2024 (CMS, 2015a). The rising cost of health insurance premiums (and other related costs such as higher copays and deductibles) is a growing burden to working American families and employers.

Despite the vast economic resources devoted to financing the health care system, unequal access to care exists, especially among vulnerable populations. Although the availability and provision of health insurance is an important factor in health equity, vulnerable populations face additional obstacles, leading to health disparities across the nation. Health disparities (a particular type of health difference that is closely linked with social, economic, and/or environmental disadvantage) adversely affect groups of individuals especially vulnerable populations. The vision of *Healthy People 2020* is a society in which all people live long healthy lives. One of the overarching goals of *Healthy People 2020* is the attainment of the highest level of health for all people. The *Healthy People 2020* framework provides structure and guidance, identifying specific areas where action must be taken and targets met so as to achieve the goals by 2020 (US Department of Health and Human Services [USDHHS], 2015a). Federal and state governments, to improve the health of the population, enact health care reform policies and laws. In the past, health care reform consisted of incremental steps, mainly targeted at the poor and older adult populations to improve health (Medicare and

Medicaid); however, with escalating health care costs, rising numbers of uninsured Americans, and concern for improvement in the quality and safety of care, a more substantive reform effort was taken. The new health care federal reform law called the Patient Protection and **Affordable Care Act (ACA)** was signed into law on March 23, 2010. The federal law requires the largest change in the financing of the American health care system since public Medicare and Medicaid programs were enacted in the 1960s. The law was designed to expand coverage, control cost, and improve the delivery of health care (Kaiser Family Foundation [KFF], 2013). A core component of the ACA is to reduce the number of uninsured individuals by expansion of the Medicaid program so that more individuals meet the expanded enrollment criteria and the establishment of marketplace subsidies for moderate-income individuals to assist with health care premium costs. Implementation of the law is occurring in increments, with full enactment of the ACA slated by 2018. The law is designed to address the issues of affordability, accessibility, and financing of health care, with focused efforts on meeting the needs of vulnerable populations. Implementation of the various provisions of the ACA has required substantial changes in public insurance programs, private health insurance market regulations, and other components of the health care system. Because of lack of bipartisan support for the original ACA, and continued bipartisan disagreements over many of the provisions, a change in the political landscape of the Senate or House of Representatives in Washington or future actions filed in the court system may result in repeal of the law, dismantling of portions of the law, or additional amendments to some of the current and future provisions. For example, one of the first contested provisions of the ACA was the requirement for most United States citizens and legal residents to have health insurance or pay a federal tax penalty beginning in 2014. The Supreme Court in June of 2012 ruled in favor of the constitutionality of this contested provision and upheld the requirement for the individual mandate. However, the court also ruled that states had the option of expanding (or not) their Medicaid programs. Expanding the Medicaid program in every state would

have increased coverage to a greater number of lower-income adults. A family of three, for example, in 2014 with an income of $27,300 or less would have been eligible for Medicaid coverage if they were living in a state that had expanded its Medicaid program. To encourage individual states to expand Medicaid coverage, additional federal tax dollars are allotted to states that have expanded coverage (KFF, 2013).

The past several years have been challenging times for state governments to arrange the implementation of the many provisions of the ACA. For example, one provision allows individuals to purchase coverage through a public or private **health insurance exchange.** The health insurance **marketplace**, or Obama care exchange, is for individuals who do not have health insurance or employer qualifying health insurance, Medicare, Medicaid, the Children's Health Insurance Program (CHIP), or other source that provide qualifying health insurance. Many individuals who qualify for marketplace coverage health insurance are eligible for financial assistance for a premium tax credit (subsidies) based on expected income for 2017. Marketplace plans must cover mandated essential health benefits, which include ambulatory patient services; emergency services; hospitalization; pregnancy, maternity, and newborn care; mental health and substance abuse services; prescription drugs; laboratory services; preventive and wellness services and chronic disease management; pediatric services, which include oral and vision care; and preexisting conditions, including pregnancy and preventive care. Plans must also have birth control benefits, and some covered contraceptive methods. Adult vision and dental coverage are not required in the mandated essential packages, but some plans may offer these benefits, or separate dental plans may be available for a separate additional premium. Marketplace plans have deductibles, co-payments, and other out-of-pocket costs for most covered services with the exception of some preventive care. All health insurance plans must cover the mandated essential health benefits, but each plan is different, with some states opting to cover additional services (HealthCare.gov, n.d.). The process for selecting and applying to join a plan can be challenging for many

individuals, especially for those with low literacy levels and/or limited health literacy. Despite greater health insurance coverage for many more individuals, issues for the newly insured include paying for monthly premiums (if applicable), knowing how to use plan benefits effectively, finding a provider, navigating the health care system, and paying additional out-of-pocket expenses of deductibles and copays. A key role of nurses is to help individuals and families overcome these barriers.

This chapter will analyze the health status of the nation compared with other countries, examine historical influences in the delivery of health care, and describe the structure and mechanisms to deliver public (Medicare and Medicaid) and private health care in the United States and select other countries, the financing of the health care system, and key federal legislation with emphasis on the provisions of the ACA of 2010, which will strive to improve teamwork and communication between all these system pieces. The greatest savings in health care expenditures could be realized if individuals engage in consistent health-promotion and disease-prevention practices and avoid costly consequences of acute and chronic disease. The ACA includes requirements for essential health benefits designed to promote health screenings and other preventative measures, hoping that savings will be realized from early detection, decreasing hospital admissions, and unnecessary hospital readmissions. Nurses need to keep abreast of the various provisions and amendments of the law to help individuals and families navigate the health care system and be politically active in influencing health policy as an **advocate** of social justice for individuals and families.

The Health of the Nation

Health, United States is an annually published document prepared by the USDHHS; it reports the health status of the nation by tracking a variety of specific, measurable health indicators. This annual report serves several key functions, but the main goal is to inform policymakers, the President, and Congress of the trends in the nation's health to guide the development of sound health policy and allocate resources to maintain and improve the health of the nation's citizens. The 2014 report indicates the health of the nation improved in many areas between 2003 and 2013 as a result of substantial funding of public health programs, research, provision of health care, and initiatives to support consumer education. Emerging trends indicate success in the reduction of morbidity and mortality for many diseases, control of widespread infectious diseases through widespread vaccination programs, improvement in motor vehicle safety, smoking cessation measures, and reduction of cardiovascular-related deaths. Life expectancy has increased for both men and women, and maternal and infant mortality rates on average are declining in many geographical locations. Heart disease remains the number one cause of death for Americans, responsible for 24% of all deaths in 2013, followed by cancer at 23% of all deaths in the same year. Education regarding leading a healthy lifestyle, controlling hypertension, smoking cessation, using cholesterol-lowering medications, and participating in routine screening has contributed to better health for many Americans, but concern about sedentary lifestyle, rising obesity trends, and chronic disease is noted. Recent national smoking cessation interventions for individuals aged 18 years or older are demonstrating some effectiveness as the percentage of individuals who smoke dropped to 17.8% in 2013, compared with 23.2% in 2000. The percentage of adults who engage in aerobic exercise and muscle strengthening increased to 20.4% in 2013 (15.1% in 2000), but other health risk factors remain problematic, with 35.5% of adults older than 20 years reported as obese between 2009 and 2012, which is an

increase from 30.5% for 1999 to 2002. The report cites the prevalence of childhood obesity as a growing concern—between 2009 and 2012, 10.2% of children aged 2 to 5 years, 17.9% of children aged 6 to 11 years, and 19.4% of adolescents aged 12 to 19 years were obese. As obesity trends often continue into adulthood, these children are at greater risk of developing diabetes, hypertension, and cardiovascular disease earlier in life and developing the sequelae of chronic disease in adulthood. Of noted concern is the rise in suicide and drug poisoning death rates in recent years. Suicide death rates rose 17% to 12.6 per 100,000 population and drug poisoning death rates involving opioid analgesics increased from 2.9 deaths per 100,000 population to 5.1 deaths per 100,000 population, with the highest rates among those aged 45 to 54 years (USDHHS, 2015a). Improvements in the nation's health have not been uniform, because factors affecting health equity include an individual's income, race, sex, ethnicity, education level, and geographical location (National Center for Health Statistics, 2014). In summary, the most effective intervention to decrease the growing cost of health care is to keep Americans healthy—preventing chronic diseases such as diabetes and heart disease with healthy eating, routine exercise patterns, and following recommended preventative measures with routine health screenings and early intervention if problems arise is needed.

Healthy People 2020

As discussed in Chapter 1, on December 2, 2010, *Healthy People 2020* was launched, providing a 10-year agenda for improving the health of all Americans. The new overarching goals are listed in Box 3-1: *Healthy People 2020*.

Box 3-1

Healthy People 2020

Overarching Goals for Healthy People 2020

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

Source HealthyPeople.gov. (2015). About healthy people. http://www.healthypeople.gov/2020/About-Healthy-People/.

One of the goals of *Healthy People 2000* was to reduce health disparities among Americans. Ten years later, Healthy People 2010's goal was to eliminate health disparities. The current 2020 goal is broader; to achieve health equity, eliminate disparities, and improve the health of all groups as measured by leading health indicators. Health disparities adversely affect groups of people who have systematically experienced greater obstacles to health on the basis of their race, color, or national origin; ethnic group; religion; socioeconomic status; gender; age; mental health; cognitive, sensory, or physical or other disability; sexual orientation or gender identity; geographical location; or other characteristics historically linked to discrimination or exclusion (USDHHS, 2015b). Individuals and groups at risk of health disparity are considered vulnerable populations (KFF, 2010b). A more complete list of vulnerable populations can be found in Box 3-2: Vulnerable Populations. Public health nursing practice promotes and preserves the health of populations, looking at the community as a whole and its effect on the health of individuals, families, and groups. Community health nursing practice promotes, preserves, and maintains the health of populations through care provided to individuals, families, and groups and studies the effect of their health status on that of the

community as a whole (Stanhope & Lancaster, 2012). A healthy thriving community is a community that is safe and inclusive and promotes a high quality of life and well-being, which can be measured by social networks, physical assets, economic opportunity, human development, and local institutions that sustain respect and support each of the dimensions (Community Health and Empowerment through Education and Research, 2015). *Healthy People 2020* supports the need for an effective public health infrastructure for planning, delivering, and evaluating public health, with the key components being a capable and qualified workforce, up-to-date data and information systems, and public health agencies capable of assessing and responding to public health needs (Office of Disease Prevention and Health Promotion, 2015).

Box 3-2

Vulnerable Populations

- Residents of rural areas
- Undocumented immigrants
- Low-income individuals and families
- Working poor
- Racial and ethnic minorities
- People with no health insurance coverage
- People with multiple chronic conditions
- People with language or cultural barriers
- The physically disabled or handicapped
- The terminally or mentally ill

- Persons with HIV/AIDS
- Alcohol or substance abusers
- Homeless individuals
- Individuals who do not speak English
- Individuals with communication difficulties
- Low education levels or illiteracy
- Anyone lacking health literacy

Health Indicators of a Nation

Standard measures used to compare the health status of the population of one nation with another are actually death indicators. Although mortality-based indicators do not directly measure the health status of the living population, the data indirectly reflect the general health of a nation and are more readily available through government and world agencies. Table 3-1, International Comparisons of Core Health Indicators, compares the average life expectancy by gender as well as infant mortality rates of populations in select countries. According to Central Intelligence Agency (CIA) statistics (CIA, 2015), the life expectancy on average (both sexes combined) in the United States in 2015 was 79.68 years compared with 81.98 years in Sweden and 81.76 years in Canada. The life expectancy in Mexico was significantly lower at 75.65 years. In 1950, life expectancy in the United States for men was 56.2 years and for women was 65.5 years (Social Security Administration, n.d.), so much progress has been made in improving the health of the nation. Overall, life expectancy rates have risen sharply in the past 60 years in the United States and other industrialized countries, but in stark comparison, life expectancy

in third world or poorer countries lags. For example, Afghanistan, a country with low levels of health care provisions, life expectancy today is on average 61.3 years. Compared with the United States, this gap is greater than 18 years, and life expectancy is less than life expectancies reported for women in the United States in 1950. During the preceding two decades, most nations have slowly increased life expectancy by 4 to 5 years (Table 3-2 for select countries). Although India, for example, is behind in life expectancy compared with other countries (average life expectancy in 2015 was 68.13 years), overall life expectancy has increased significantly in the last 2 decades (CIA, 2015).

TABLE 3-1

International Comparisons of Core Health Indicator Estimates for 2015

	Afghanistan	Canada	France	Germany	Mexico	Sweden	United Kingdom	United States
Life expectancy at birth: males (years)	60.5	79.15	78.65	78.26	72.88	80.09	78.37	77.32
Life expectancy at birth: females (years)	62.0	84.52	85.01	83.0	78.55	83.99	82.83	81.97
Life expectancy at birth: both sexes (years)	61.3	81.76	81.75	80.57	75.65	81.98	80.54	79.68
Infant deaths per 1000 live births	66.0	4.65	3.28	3.43	12.23	2.6	4.38	5.87

Infant mortality rates (see Table 3-1) are one of the most important indicators of the health of a nation because they are associated with factors such as maternal health and access to health care. The US infant mortality rate (number of deaths in the first year of life) estimated in 2015 was reported as 5.87 (number of deaths of infants in the first year of life per 1000 live births), a dramatic improvement from 29.2 reported in 1950 but higher than mortality rates in other developed nations (CIA, 2015). Mexico has an infant mortality rate of slightly more than 12, which is lower than that of other poor nations such as Ethiopia, which has an infant mortality rate of more than 53. Outliers for an extremely high infant mortality rate are Afghanistan, reporting 66.0, and Mali, reporting an estimate of more than 102 in 2015 (CIA, 2015) (Figure 3-1). The rationale of why the United States ranks less favorably in this health indicator than other industrialized nations is attributed to a number of factors. According to a working

paper from the National Bureau of Economic Research (Chen et al., 2014), there is a lack of comparable microdata sets across countries that may account for about 40% of the difference in infant mortality rates between the United States and comparable countries because of the variability in the reporting of births near the threshold of fetal viability, so there are differences in how and what data are collected and used. This is also a factor in comparing neonatal mortality rates (infant deaths within the first 28 days of life) as countries may differ in reporting data based on gestational age and birth weight and survival. In the United States, low birth weight and congenital malformations were the two top reasons (38% of all infant deaths) in 2013 (CIA, 2015; Peterson Center on Healthcare & Kaiser Family Foundation Partnership, 2015; Mathews et al., 2015). Despite data collection and reporting variations, the United States overall has large disparities in health status by geographical areas, race, ethnicity groups, social class, and education levels. For example, infant mortality rates for black, non-Hispanic babies were more than twice those of white, non-Hispanic babies. According to 2013 figures (Figure 3-2), the infant mortality rate for white, non-Hispanic infants in the United States was 5.1, which is below the overall average for all races (6.0 years in 2013), but black, non-Hispanic babies had a disproportionately high rate of more than 10 infant deaths in the first year of life and American Indian/Alaska Natives had a rate of 7.6 deaths per 1000 live births in 2013 (Peterson Center on Healthcare & Kaiser Family Foundation Partnership, 2015). Preliminary data from the USDHHS reported similar infant mortality rates for 2013 (Table 3-3). Although the infant mortality rate from 2000 to 2013 in the United States improved by about 13%, there has been a persistent racial disparity in the United States, especially among black, non-Hispanic infants. The US infant mortality rate is higher than that of the other industrial nations presented in Table 3-1. A number of characteristics are reported with birth and infant death data sets that include in addition to race and ethnicity, infant mortality rates in which pregnancy care was started, smoking status during pregnancy, and education level of the mother. The lowest infant mortality rates are reported when a mother seeks

prenatal care in the first trimester of pregnancy, is a nonsmoker during pregnancy, and has attained a bachelor's degree or higher (Table 3-4). Mothers who sought late or no prenatal care, smoked during pregnancy, or had less than a high school diploma had the greatest number of infant deaths. Large differences in infant death rates are readily apparent, as shown in Figure 3-3. The 2003 to 2005 the infant mortality rate of white mothers aged 20 years older with a college education was 4.2, whereas that of Asian women was even lower, at 3.8. These statistics are much more congruent with those of other industrialized countries. African American women with less than a high school education have the highest infant mortality rates, reported as 15.1. For most races and ethnicities, the higher a woman's educational achievement, the lower the overall infant mortality rate, as shown in Figure 3-1. In research terms this indicates a positive correlation between educational attainment of women and infant mortality rates. To improve health indicators and reduce health disparities of a population, interventions to promote educational attainment of women at least through high school need to occur as one strategy to decrease infant mortality rates. The mortality rate for infants of unmarried mothers (7.96) is 73% higher than that for infants of married mothers (4.60). Geographical variations also exist within the United States, with the highest percentage infant mortality rates reported in Mississippi at 9.6, Louisiana at 8.69, Alabama at 8.60 (compared with the national average of 5.96), and nine states reporting infant mortality rates of less than 5.0 (i.e., Massachusetts 4.18, Iowa 4.25, Vermont 4.35, California 4.76, Connecticut 4.79, New York 4.93) (Mathews et al., 2015). In summary, decreasing the nation's infant mortality rates will require community interventions to decrease teen pregnancy, promote educational attainment for all women to high school level or greater, and provide targeted interventions for specific racial groups and geographical areas.

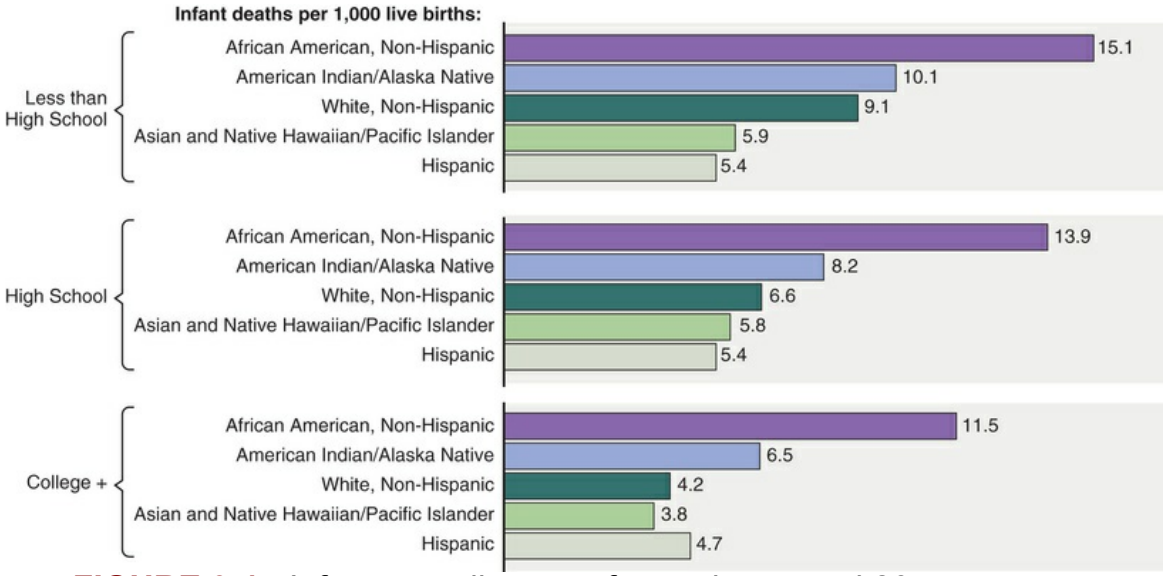

FIGURE 3-1 Infant mortality rates for mothers aged 20 years or older by race/ethnicity and education, 2003 to 2005. Data reported from 37 states, the District of Columbia, and New York City. (Data from the Centers for Disease Control and Prevention/National Center for Health Statistics, National Vital Statistics System, linked birth/infant death dataset. From *Health,* United States, 2008, Table 19.)

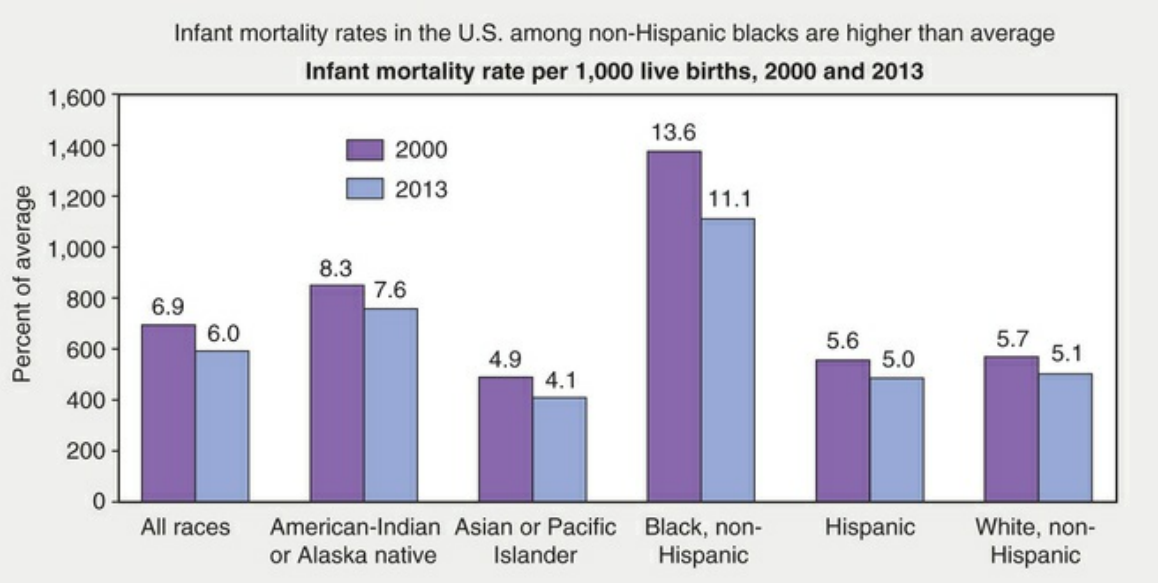

FIGURE 3-2 Infant mortality rates in the United States among non-Hispanic blacks are higher than average. (From National Vital Statistics System, National Center for Health Statistics, Centers for Disease Control and Prevention. Slide available from Kaiser Family Foundation.

Historical Role of Women in Health Promotion

Nurses have a long tradition of involvement in health promotion, beginning with Florence Nightingale, the founder of modern nursing. While caring for wounded soldiers in a British camp outside Constantinople, Turkey, in 1854 during the Crimean War, she fought for hospital reform by crusading for nutritious food, cleanliness, and sanitation. She provided leadership for a group of nurses and comfort to the soldiers. Her careful recordings of care outcomes quantified needed reform in health promotion (University of Alabama at

Birmingham, 2016). Later, Lillian Wald, appalled by the lack of medical care, ignorance, and living conditions of the poor in 1893, developed a settlement program in New York City that trained nurses, provided care to families, and developed education programs for the community. Wald, a leader in political activism, spearheaded organized public health in the direction of health promotion for families and communities (Henry Street Settlement, 2016). These pioneers and others set the stage for nurses' unique role in health promotion.

A Safer System

The health care delivery system in the United States is experiencing significant changes sparked by health care reform and recommendations from large organizations involved in forming health policy. One of the large nonprofit organizations with seven divisions is the National Academies of Science, Engineering, and Medicine. One of the divisions, named the Institute of Medicine (IOM), conducts research from a systems approach to advise the nation's leaders in improving health. On March 15, 2016, the division that focuses on health and medicine (previously known as the IOM) was renamed the Health and Medicine Division (HMD). Several early IOM reports were instrumental in advising on the need to revise health policy to change the structure of health care delivery to deliver safer care. The 1999 IOM research report *To Err Is Human: Building a Safer Health System* (IOM, 1999) focused on prevention of medical errors, which account for approximately 98,000 deaths in hospitals each year. The startling findings concluded that the health care system, not bad practitioners, is the basic cause of medical errors. In 2003 the IOM released another report, *Keeping Patients Safe: Transforming the Work Environment of Nurses* (IOM, 2003). This report shows that work environments in hospitals and nursing homes contribute to nurses' errors. Four main problem areas in nurses' work environments were identified: organizational management, workforce management, work design, and organizational culture. The researchers found that increased nurse staffing ratios, fewer nurses, mandatory overtime, inadequate continuing education, and lack of nurse involvement in decisions about client care create an environment that contributes to error-making. The data the IOM provided in this project support a direct link between nurse staffing and work environment with patient outcomes. Other efforts by the IOM to improve the health of the nation include the 2006 report *Preventing Medication Errors: Quality Chasm Series* (IOM, 2006). The report found in any given week, medication errors in prescribing or

taking medication were not only common but also costly to the nation and recommended a comprehensive approach to decreasing the prevalence of medication errors by making changes in the health care system. A report released in January of 2012 discussed how standards of care can be defined as the level of health and medical care capable of being delivered when preparations are being made for public health emergencies such as pandemic influenza, large-scale earthquake, or any major disaster scenario in which the health system may be destroyed or stressed (IOM, 2012). The IOM has made recommendations in other areas promoting safety within the health care system. For example, in 2011 recommendations were made to improve transparency in the reporting of health information technology and promoting health literacy to encourage prevention and wellness, and in 2014 an IOM report, *Dying in America, Improving Quality and Honoring Individual Preferences Near the End of Life* (IOM, 2014) provided direction on improving end-of-life care for this vulnerable population. The IOM (now the HMD) has been productive in releasing hundreds of reports and workshop summaries of pressing concerns related to health and the health care system. New reports are generated each month by the HMD and can be found on the National Academy of Science website (see http://nationalacademics.org). Current topic areas include public health (367 reports), biomedical and health research (273 reports), quality and safety (222 reports), diseases (220 reports), health services, coverage, access (217 reports), and select populations and health disparities (163 reports). Other subject areas include food and nutrition, health care workforce, global health, veterans' health, mental health, education, aging, and women's health. The HMD in the first few weeks of April 2016 released six reports on topics as varied as vector-borne diseases, public health problems of hepatitis B and hepatitis C, and systems practices for the care of socially at risk populations, while in March 2016, ten reports were released pertaining to economics, protection of children, cancer care in low-resource areas, ovarian cancer, and Agent Orange updates and veterans. To provide safe, evidence-based care, nurses have a responsibility to be lifelong learners to stay abreast of new scientific

findings and advocate health care policy changes that improve the health of the communities in which they practice and extend to the greater global population. Although health care is often equated with medical care, which focuses on the treatment of illness, this chapter presents the evolution and ongoing development of a broader concept of health based on the definition given in Chapter 1.

Global Health

The overriding objective of the World Health Organization (WHO) is to influence health opportunities and outcomes for all people so that they can attain the highest possible level of health. WHO recognizes the importance of families and health promotion, and has contributed to the family health policies of many nations by shaping global awareness for health promotion. The current agenda of WHO involves the following six goals: promoting development; fostering health security; strengthening health systems; harnessing research, information, and evidence; enhancing partnerships; and improving performance (WHO, n.d.a). Internationally, shrinking health care budgets have resulted in a variable level of achievement of these goals. In developing nations, such as those in Latin America and Africa, huge inequities in health care persist.

Historical Perspectives

The complexities of the US health care system necessitate an understanding of the system as a whole before one can focus on the intermingled causative factors that have created a fragmented system of health care delivery. Many of today's problems have their roots in the decisions and directions of the past. It is not possible to identify and analyze current problems or to devise solutions without first exploring how the system developed. The relevance of the divergence between preventive and curative measures is apparent when the organization and financing of the delivery system are examined. The United States has established a system that uses two basic divisions of society to provide service: the public sector and the private sector. The merger of public health and welfare policies in the public sector is rooted in the Puritan ethic inherent in the historical development of the United States. The current focus on managed care as both an organizational strategy and a financing mechanism is highlighted in a discussion of how health care is delivered and financed.

History of Health Care

Early Influences

Historical records of early civilizations (Egyptian, Indian, Chinese, Aztec, and Greek) show that ancient peoples were concerned with disease and practiced various methods of treatment. The earliest views of health can be seen as holistic in the sense that they emerged from an integrated worldview. Primitive peoples understood illness in mystical terms: sickness and cure theories were tied to the cosmic view of life, with natural and supernatural forces often inseparable. Most religions include a person's hygiene as part of their practice. For thousands of years, epidemics were viewed as divine judgments on human wickedness, with a gradual awareness that pestilence (any epidemic disease with a high death rate) has natural causes such as climate and other aspects of the physical environment. During the Middle Ages, infectious diseases in epidemic proportions (leprosy, bubonic plague, smallpox, and tuberculosis [TB]) were the leading causes of death. Clearly, health was viewed in terms of survival and absence of disease.

Industrial Influences

The population of the Western world began to increase during the 1600s, when America was first being explored. The New World had many things to offer explorers. An adequate food supply made it possible for the population to live longer, and advances in transportation made distribution of food supplies and other goods and services possible. Manufacturing advances during the 18th century, through the invention of the flush toilet and cast iron pipe, made sanitary engineering possible, saving many lives by preventing diseases such as typhoid, paratyphoid, and gastroenteritis.

Socioeconomic Influences

Although the Elizabethan poor laws (1601) in England provided a system of relief for the poor, which included infants, sick, and older people, and laborers in the workhouses, a new poor law was enacted in 1834 that was based on the harsher philosophy that regarded pauperism among able-bodied workers as a moral failing. If the worker did not earn a subsistence-level income, the attitude toward that worker was suspicious and punitive. These poor laws were the legal implementation of the Protestant work ethic that the Puritan forebears brought to the United States. According to this view, people are held directly accountable for their state in life, and health maintenance is the responsibility of the individual. The far-reaching implications of this ethic can be seen today in the organization, financing, and delivery of health services.

Public Health Influences

Edwin Chadwick (1800–90) is known as the father of British and American public health. Chadwick established the English Board of Health, which emphasized environmental sanitation but excluded physicians outside times of crisis. Additionally, Chadwick was Secretary of the Poor Law Commission, which strove to improve the health of the masses for economic reasons. Chadwick's rationale was that disease among the poor was a major factor in their inability to support themselves. Therefore, governmental health and welfare policies have been joined in England since the 19th century.

Lemuel Shattuck, a leader of the public health movement, began the movement in the United States. He used the British system as the model, with public health services and welfare combined, despite the contradictory emphasis. Public health has focused on improving the health of the poor, whereas welfare has dictated subsistence at the minimal level. The influence of the Puritan ethic on the American health care system is apparent in the emphasis on the value of work and the attitude toward the poor. Today, health and welfare departments continue their contradictory approach to the poor.

Scientific Influences

Until the 20th century, epidemics of infectious disease (plague, cholera, typhoid, smallpox, and influenza) were the most critical health problems and major causes of death and disability for Americans. Scientific advances during the 19th century by Louis Pasteur (germ theory), Robert Koch (origin of bacterial infection), Joseph Lister (antisepsis), and Paul Ehrlich (chemotherapy) expanded public health from its earlier concentration on sanitation to control of communicable diseases through a broad biological base. Public health became an important force in decreasing death rates and increasing life expectancy through the application of bacteriology. International environmental conditions were improved by the development of systems that safeguard water, milk, and food supplies; promote sanitary sewage disposal; and monitor the quality of urban housing.

Between 1936 and 1954 the discovery and use of sulfonamides and other antibiotics to treat bacterial infections reduced the death rate to its lowest point in history, with deaths caused by primary infections reduced to 4%, as compared with 33% only 50 years earlier (in 1886). The death rate did not change significantly between 1954 and the mid-1960s. Another decline in the death rate began after the mid-1960s and has continued (with the exception of a slight increase in 1995) with the control of many infectious diseases (Arias & Smith, 2003). As the life expectancy of the population increases, chronic diseases and comorbidities increase as well. Data from 2013 revealed heart disease, malignant neoplasm, chronic lower respiratory tract disease, unintentional injury, cerebrovascular disease, Alzheimer disease, diabetes, influenza and pneumonia, nephritis, and suicide in descending order are the top 10 leading causes of total death in the United States as reported by the Centers for Disease Control and Prevention (CDC, 2016).

Despite the progress in conquering infectious diseases, in vulnerable populations infections are once again among the top leading contributors to death in the United States. Influenza and pneumonia are the sixth leading cause of death for children aged 1 to 4 years, the seventh for children aged 5 to 9 years, and the eighth for

children aged 10 to 14 years. Although not in the top 10 causes of death, some diseases that were thought to be under control, such as measles and TB, are resurfacing and new pathogens are emerging (CDC, 2016).

Some infectious diseases are difficult to eradicate from the population (e.g., TB). The most effective strategy for eliminating TB is to monitor those infected to ensure completion of treatment is by direct observed therapy, which requires the monitoring of a person's medication adherence for first-line drugs for 8 weeks and continuation of treatment for 4 to 7 months. Individuals who do not finish the prescribed medication regimen correctly are at risk of developing resistance to one or more first-line medications. Treatment of drug-resistant TB becomes more complicated and costly, and drug-resistant TB is difficult to eradicate. Resources are needed at local public health departments to provide monitoring and follow-up in this typically elusive TB-infected population. The National TB Surveillance System reports declining TB incidence on average, with 2013 data reporting the lowest number of TB cases in the United States since national reporting began in 1953. This is significant progress since TB cases peaked in 1992. In the United States in 2013, 65% of all TB cases and 90% of multiresistant cases occurred among people born in other countries. As reported by the CDC, in the United States in 2014 there were 2.96 TB cases per 100,000 persons. Foreign-born individuals in the United States had a 13 times higher rate (15.4 cases per 100,000 in 2014) than individuals born in the United States (1.2 cases per 100,000). The rates of TB in ethnic and racial populations differ as well in the United States. Native Hawaiians and other Pacific Islanders (16.9 TB cases per 100,000) and Asians (17.8 cases per 100,000) have the highest rates. Black or African Americans (5.1 cases per 100,000) and American Indians or Alaska Natives and Hispanics or Latinos both have the same rate of 5.0 cases per 100,000, whereas whites are reported to have the lowest rate at 0.6 cases per 100,000. To eliminate TB cases nationally will require adequate local community resources, targeted to groups at risk. Despite the relative low case rates in the United States, TB caused 555 deaths in 2013, up from 510

deaths in 2012 (CDC, 2015).

Globally, TB is the most common infectious disease and one of the world's deadliest diseases, with one-third of the world's population being infected. Major efforts have been put in place for TB prevention, screening, diagnosis, and treatment. WHO estimates 43 million lives were saved between 2000 and 2014 with targeted measures. Despite this progress, in 2014, 1.5 million people (1.1 million HIV positive and 0.4 million HIV negative) died of TB. This includes 140,000 children. TB is the leading cause of death in individuals with HIV. Targeted interventions have been distributed over wide regions of high disease–burdened countries because the risk of infection of the population is more widespread. Regions in Africa, for example, have 28% of the world's cases, with 281 cases for every 100,000 people. Indonesia was estimated to have 1 million new cases in 2014. WHO reported that in 2013, 9 million people around the world became ill with TB. New strains of drug-resistant TB are now emerging that are resistant not only to isoniazid and rifampin, which are the most effective first-line TB treatment drugs, but also to second-line anti-TB drugs. TB remains an urgent public health problem, with more than 80% of the cases identified in 22 high-burden countries. Global interventions to reduce TB include targeted population- and age-specific interventions such as administration of the bacille Calmette-Guérin (BCG) vaccine to infants and small children in countries where TB is more common. The vaccine is given only if the child has negative TB skin test findings and cannot be separated from adults who are untreated or ineffectively treated for TB (CDC, 2015; WHO, 2015).

An effective, comprehensive public health system is imperative to enable the United States to respond to local, national, and global concerns. As new diseases emerge, older diseases reemerge (sometimes in drug-resistant forms), and natural and man-made disasters occur, a functioning public health system is warranted. The ACA calls for the establishment of a council within the USDHHS to be known as the National Prevention, Health Promotion, and Public Health Council, required to provide coordination and leadership at

the federal level among all federal departments and agencies. The council is charged with obtaining input from relative stakeholders to develop a plan to improve the health status of Americans and reduce the incidence of preventable disease, disability, and illness, which will require the integration and coordination of many of the divisions of the USDHHS (Office of the Legislative Council, 2010). The CDC is the frontline agency for providing national health security and must remain vigilant in rapidly detecting and controlling disease outbreaks in the United States and abroad. The CDC's Emergency Operations Center is the command center for monitoring and coordinating emergency response to public health threats in the United States and worldwide, such as pandemic influenza, natural disasters, and terrorist attacks. Recent global outbreaks of the Hendra virus (1994); H5N1 bird flu (1997); Nipah virus (1999); severe acute respiratory syndrome–associated coronavirus (2003); monkey pox, mad cow disease, and avian flu (2006); H1N1 (2009); and Ebola (2014) pose challenges to global public health (CDC Foundation, 2012, 2016). According to the CDC, influenza pandemic occurs approximately three times a century, and in 1918 a severe influenza pandemic killed about 1% of those who contracted the influenza. When the bird flu virus H5N1 emerged in 1997, the CDC and others began tracking the novel form of influenza, fearing a potential pandemic. Because about 60% of individuals who contracted bird flu died, concern heightened when another influenza virus, H1N1, was first recognized in Mexico in 2009. The virus was identified as influenza A, H1N1, the same virus responsible for the 1918 Spanish influenza pandemic, which was responsible for 50 million deaths. Fearing another deadly pandemic, the CDC took quick actions and developed a vaccine that was distributed to as many Americans as possible, targeting infants, young adults, and pregnant women. Although the H1N1 flu outbreak of 2009 (known also as swine flu) killed 12,500 individuals, millions of Americans were protected against H1N1, preventing thousands of hospitalizations and deaths. The CDC remains on constant alert for new, deadly influenza viruses and other airborne diseases (CDC Foundation, 2012, 2016).

Special Population Influences

The second goal of *Healthy People 2020*, as previously stated, is to achieve health equity, eliminate disparities, and improve the health of all groups. Vulnerable populations, especially those living in poverty, are at great risk of experiencing health disparities (USDHHS, Office of Minority Health, 2012). For many of these disadvantaged people, the issues of preventing disease and promoting good health are often secondary to the problems associated with everyday survival. Determinants of health in a population are related strongly to socioeconomic status and education level, with populations in the lower strata having worse outcomes. However, individual lifestyle behaviors, including dietary choices, level of physical activity, use of alcohol and tobacco, substance abuse, and risky sexual behavior, play a significant role in the health status of an individual. Access to health care for prevention, early detection, and treatment is paramount in diminishing health disparities, but programs promoting positive individual lifestyle behaviors are also needed (USDHHS, Office of Minority Health, 2012) (Box 3-3: Diversity Awareness).

Box 3-3

Diversity Awareness

Health and Human Services Action Plan to Reduce Racial and Ethnic Health Disparities

Community-Driven Approach to Reduce Health Disparities in the United States

As a nation, health equity does not exist especially among racial and ethnic populations. Health disparities, as discussed in the report, are differences in health outcomes that are closely linked with social, economic, and environmental disadvantage, which are often driven by the social conditions in which individuals live, learn, work, and play. Marked differences in social determinants, such as poverty, low

socioeconomic status, and lack of access to care, exist along racial and ethnic lines, leading to poor health outcomes. The economic burden between 2003 and 2006 attributable to health disparities was estimated to be $1.24 trillion. The major dimensions of racial and ethnic health disparities outlined are:

- Lack of insurance negatively affects the quality of health care received by minorities. One-third of the population consists of racial and ethnic minorities but constitutes more than half of the 50 million individuals without health insurance.

- Minorities are overrepresented among the 56 million people in the United States who have inadequate access to a primary care physician. Minority children are less likely than non-Hispanic white children to have a usual source of care.

- Racial and ethnic minorities often receive poorer quality of care and face more barriers in seeking care, including preventive care, acute treatment, and chronic disease management, than non-Hispanic whites.

- African Americans have higher hospitalization rates from influenza than other populations, and African American children are more than four times as likely to die of asthma as non-Hispanic white children. Higher obesity rates in the African American population contribute to the onset of diabetes, hypertension, and cardiovascular disease.

As the demographics of the United States continue to become more diverse, nurses need to be culturally competent as one strategy for eliminating racial and ethnic disparities. In the 2004 IOM report titled *In the Nation's Compelling Interest: Ensuring Diversity in Health Care Workforce,* diversity in the workforce was a key element of patient-centered care. Efforts to match the ethnic and racial composition of the health care workforce with the US population will contribute to addressing health disparities. Providers who speak a second

language will also be needed because 24 million adults have limited English proficiency. Shortages of primary care providers in underserved areas significantly affect the health of ethnic and racial minorities. The primary care nurse practitioner is ideally suited to care for underserved populations in urban and rural areas. Additional funds from the ACA are funding Communities Putting Prevention to Work programs, which support statewide and community-based policy and environmental changes in nutrition, physical activity, tobacco control, and other factors that harm people's health. *Healthy People 2020* provides a comprehensive set of 10-year national goals and objectives with 42 topic areas and more than 600 evolving objectives. The leading health indicators outline high-priority health issues. One of the goals is to ensure that federal, state, tribal, and local health agencies have the necessary infrastructure to effectively provide essential public health services. A capable and qualified workforce, up-to-date data and information services, and public health agencies capable of assessing and responding to public health needs are three components necessary for an effective public health infrastructure (USDHHS, 2011). Nurses can play key roles as educators and providers of care in their communities to meet the needs of vulnerable populations and close the health disparity gap.

Political and Economic Influences

Political and economic considerations influence the health care system, and politics determines the decision makers who will negotiate a desired outcome. Economics defines the resources that are distributed and the manner in which they are distributed. The effect of economics and politics on the delivery of health care is illustrated by the situation in the United States following the Great Depression. Roosevelt's New Deal had an effect on health care, specifically in the

passage of the Social Security Act in 1935, which authorized grants-in-aid to individual states to improve state and local public health programs. Funds were available for categorical assistance programs, with cash grants first given to needy blind and older individuals and later to disabled people. Medical care, through subsequent amendments, was an allowable budget item, but payments were often distributed for food, shelter, or other needs. Later, the Social Security Act resulted in the development of programs such as Medicaid and Medicare.

Split Between Preventive and Curative Measures

The link between environmental health and personal medical care developed when sanitarians (people who work to maintain a clean environment) realized that their efforts alone were not sufficient to prevent and cure the diseases of the population as a whole; improvement of personal health was also necessary. Early preventive services directed toward individuals originated in medical practice rather than public health but were limited to welfare medicine (caring for individuals through state programs). Community health centers that developed in America before World War I limited their scope to prevention and health education and, with the exception of some prenatal clinics, were generally located in poor neighborhoods. Delivery of preventive services developed separately from clinical medicine and became associated with public health. Most physicians, educated in hospitals, were interested in individuals for whom prevention had failed and whose illnesses brought them to the hospital ward.

Despite the separation of preventive and treatment services, the benefits of prevention were eventually incorporated into clinical medicine for individuals. Preventive and early detection measures became a part of pediatrics and obstetrics during the early part of the 20th century, when vaccines and vaginal cytology examinations became available and accepted. Later in the 20th century, internal medicine incorporated early detection of diseases such as diabetes, glaucoma, obesity, and hypertension. A shift to preventive medicine

for the individual occurred, but the separate educational programs for public health and medicine still divided these areas. Not until the 1960s did the emphasis begin to turn from individual to societal values (Freyman, 1980).

This new emphasis on societal values parallels another evolution in the role of health in society. Greater governmental involvement in financing the health care delivery system has improved access to health care for many populations. Technological developments include computerized medical records, which should improve access to care through better communication with laboratories, primary care offices, hospitals, and care delivery agencies. The Patient Protection and Affordable Care Act (PPACA) of 2010, more commonly known as ACA, reformed certain aspects of the private health insurance industry and public health programs, increases coverage for individuals with preexisting conditions, and expands access to insurance for a projected 30 million more Americans (Office of the Legislative Council, 2010). This sweeping mandate extends a heavy layer of federal and state oversight, and since 2014 requires most Americans to obtain or purchase health insurance through a public or private plan, significantly diminishing the number of individuals who are uninsured.

Organization of the Delivery System

The health care delivery system in the United States is a mammoth system composed of a network of public and private interrelated and in some cases overlapping components, designed to provide health care to the American people. The structure and financing of the health care delivery system is a system of multifaceted and complex interrelationship involving providers, consumers, and settings, with both the private sector and the public sector providing services. The public sector includes voluntary and nonprofit agencies, and official or governmental agencies. The USDHHS is the principal federal regulatory agency whose mission is to enhance and protect the health and well-being of all Americans by providing effective health and human services and fostering advances in medicine, public health, and social services (USDHHS, n.d.b). Delivery of services is organized on three levels in both sectors: local, state, and national. Each of the three levels consists of private providers combined with official or voluntary public agencies. The nurse is often the professional who assists the health consumer to navigate throughout the complex delivery system; therefore a basic understanding of the system's organization is essential.

Private Sector

Independent Practice

Traditionally, a person enters the health care delivery system by contracting directly with a health care provider for individual care on a fee-for-service basis. Free choice of the provider has been the hallmark of the American free-market system. However, more recently physicians and other health care providers have been working within managed health care organizations. Although private practice traditionally has been disease oriented, the current emphasis on primary care necessitates a much broader perspective. Primary care involves continual and comprehensive care that includes efforts

to keep people as healthy as possible and to prevent disease.

Private care may be delivered in numerous settings, from inpatient (hospital or extended care facility) to outpatient (ambulatory) settings. Outpatient care is defined as any health care services that are not provided on the basis of an overnight stay in which room and board costs are incurred. Ambulatory settings include two major categories: care provided by owners and providers and care provided in service settings (Box 3-4). These categories overlap because many providers practice in their own offices and contract with one or more managed care organizations.

Box 3-4

Types of Ambulatory Care Settings

- *Owner provider:* Hospitals, community health agencies, managed care organizations, home health organizations, insurance agencies

- *Service settings:* Hospital-based clinics/centers, solo or group medical practices, ambulatory surgery and diagnostic procedure centers, telehealth service environments, university and community hospital clinics, military and settings within the Department of Veterans Affairs, nurse-managed clinics, managed care organizations, colleges and educational institutions, free-standing community facilities, care coordination organizations, walk-in clinics (some clinics are free clinics where patient-centered care can be provided for minimal or no fee—these types of clinics are an important safety net for vulnerable populations), urgent care centers, outpatient surgery centers, chemotherapy and radiation therapy centers, dialysis centers, neighborhood and community health centers, diagnostic and mobile imaging centers, occupational health centers, women's health clinics, wound care centers, fitness-wellness centers, health department clinics, nursing centers

Source American Academy of Ambulatory Care Nursing. (2011). *Definition of professional ambulatory care nursing report March 8, 2011.* Sudbury, MA: Jones & Bartlett.

Nursing centers are nurse-managed health centers, often situated in medically underserved rural and urban areas that primarily serve vulnerable populations in the provision of primary care to individuals and families. Nursing centers trace their origin to the Henry Street Settlement for the sick and poor of New York City, founded by Lillian Wald in 1893 and another visionary, Margaret Sanger, who opened the nation's first birth control clinic. The modern movement to establish nursing centers began in 1965 when the nurse practitioner role was created, which allowed nurses to provide primary care to individuals and families. Nursing centers (ambulatory care centers, family practice nursing centers, community nursing centers, and birthing centers) have provided high-quality nursing care from certified nurse midwives, nurse practitioners, and other advanced practice nurses (APNs). A number of nursing centers are academic nursing centers, established to provide nursing services to communities, learning experiences for students, and settings for faculty practice and research. The key components of a community nursing center include the following: a nurse as chief manager; a nursing staff that is accountable and responsible for care and professional practice; and nurses as the primary providers of care. Using a multidisciplinary collaboration framework, nurses have the opportunity to provide comprehensive primary care services, including a focus on wellness and health promotion, public health programs, and targeted interventions for populations with special needs. The Institute for Nursing Centers is a network of organizations whose focus is to promote and enhance the work of nursing centers by providing educational programs as well as a national repository of data for nurse-managed health centers funded by the W.K. Kellogg Foundation. Members of the Institute for Nursing Centers also provide mentoring and consultation to support colleagues in developing and advancing nursing centers (Institute for Nursing Centers, n.d.). The ACA specifically addresses nurse-managed health centers, describing them as a nurse practice arrangement managed by APNs who provide primary or wellness services to underserved or vulnerable populations.

Advanced practice nurses (APNs), an umbrella term for master's or doctoral prepared nurses who practice in the roles of nurse practitioners, clinical nurse specialists, nurse midwives, or nurse anesthetists, are well suited to provide cost-effective, quality care to individuals and their families, as well as to serve economically disadvantaged and vulnerable populations. APNs not only have specialized clinical knowledge and skills at the master's or doctoral level but also have pursued an advanced curriculum that includes research and theoretical foundations to determine best practices, evaluate health policy issues, and understand the intricacies of the health care system and financial management. Nurse practitioners play a key role within the health care system and often care for vulnerable populations in rural areas and inner cities, as well as practice in primary, acute, and long-term care settings.

Move to Managed Care

Before the 1990s the traditional means for paying for health care was with **indemnity insurance plans.** A person would choose a physician or care provider and receive care, and the provider would either bill the individual's **insurance** company or be paid on a **fee-for-service** basis. Each separate service generated a professional fee, and the provider would receive payments directly from the insurance plan; alternatively, the individual would pay the provider, file an insurance claim for each covered expense, and receive reimbursement. The provider had autonomy to treat the person without oversight from the insurance company. In a traditional fee-for-service insurance system, there are no incentives to constrain cost and care (Barr, 2011). In an effort to control costs, managed care began to regulate the use of health care. Physicians or physician groups contracted with an insurance company for a negotiated fee-for-service, usually at a discounted rate. Today, managed care plans include a network of individual providers or physician groups, and individuals who choose to seek care from health care providers within their network usually have full coverage with or without a copayment. Individuals who choose health care providers outside the managed care network

may not be covered, may be covered for a lesser amount, and or may have additional copayment costs, and thus face greater out-of-pocket expenses. Within the network, a person has a **primary care provider** who serves as a **gatekeeper** and is the foundation of the **managed care** concept in controlling health care costs within the organization. The primary care provider may be a physician, a physician assistant, or an APN. Physician primary care providers are usually general or family practitioners, but they may also be internists, pediatricians, or obstetrician-gynecologists. Physician assistants are educated and prepared to work under the direct supervision of physicians, whereas APNs who serve as primary care providers are typically nurse practitioners or certified nurse midwives. The term "gatekeeper" is a common managed care term, and the primary care provider has the role to coordinate and oversee an individual's care. The principal force behind the growth of managed care is the belief that health care costs can be controlled by managing the way in which health care is delivered and costs can be controlled because providers of care must be careful to provide only care that is absolutely necessary. Managed care plans are arranged agreements with a group of physicians, hospitals, and other health care providers to provide care at a certain cost (Barr, 2011). The gatekeeper concept is designed to manage the individual's use of resources, to reduce self-referral to specialists, and to protect the individual from unnecessary procedures and overtreatment (Shi & Singh, 2013). Decreasing hospital admission rates, readmittance to acute care, and costly procedures as well as limiting an individual's ability to self-refer to specialists is designed to achieve successful containment of health care costs. An oversupply of physician specialists has occurred in some areas, and a lack of primary care providers occurs in many rural areas; thus nurse practitioners are well suited to provide primary care. Providers of specialty care typically earn higher salaries than primary care providers, making career selection in a specialty area more attractive. Box 3-5 provides a glossary of key terms used in managed care.

Box 3-5

A Glossary of Managed Care Terms

Access to health care: The degree to which individuals are inhibited or facilitated in their ability to gain entry to and to receive care and services from the health care system.

Beneficiary: Any person, either a subscriber or a dependent, eligible for service under a health plan.

Benefits: The dollar amount available for the cost of covered medical services.

Blue Cross/Blue Shield: A combined medical plan offered through a worker's place of employment that combines both hospital and physician coverage.

Capitation: A fixed amount of payment per individual, per year, regardless of the volume or cost of the services each client requires.

Copayments: A fixed dollar payment that is made by the individual to the provider at the time of service.

Cost sharing: Provision of an insurance policy that requires the insured to pay some portion of the covered expenses (does not refer to or include the cost of the premium).

Deductible: A fixed dollar amount that the individual must pay before reimbursement begins.

Gatekeeper: A physician or advanced practice nurse who provides primary care and who makes referrals for emergency services or specialty care.

Health care policy: Decisions, usually developed by government policymakers, for determining present and future objectives pertaining to the health care system.

Health maintenance organization (HMO): A prepaid health plan delivering comprehensive care to members through designated providers, having a fixed monthly payment for health care services, and requiring members to be in a plan for a specified period.

Indemnity: Monies paid by an insurer to a provider, in a predetermined amount in the event of a covered loss by a beneficiary.

Independent practice association (IPA): An organization that physicians in private practice can join so that the organization can represent them in the negotiation of managed care contracts.

Managed care: A health care plan that integrates the financing and delivery of health care services by using arrangements with selected health care providers to provide services for covered individuals. Plans are generally financed by capitation fees. There are significant financial incentives for members of the plan to use the health care providers associated with the plan.

Out-of-pocket expenditures: The portion of medical expenses an individual is responsible for paying includes all health care goods and services, co-insurance fees, deductibles, and any amounts not covered as part of a health insurance plan (premiums paid for health insurance are counted as health insurance).

Point-of-service (POS) plan: A plan that contains elements of both HMOs and PPOs. They resemble HMOs for in-network services in that they both require copayments and a primary care physician. Services received outside the network are usually reimbursed on a fee-for-service basis

Preferred provider organization (PPO): A health plan generally consisting of hospital and physician providers. The PPO provides health care services to plan members usually at discounted rates in return for expedited claims payment.

Primary care: Basic health care that emphasizes general health needs rather than specialized care.

Primary care provider: A physician or APN who provides basic and routine health care services usually in an office or clinic.

Reimbursement: Payment of services. Payment of providers by a third-party insurer or government health program for health care services.

Self-insured plan: Plan offered by employers and other groups that directly assume the major cost of health insurance for their employees or members.

Third-party payer: In health care finance, this is an insurance carrier, Medicare, and Medicaid or their government-contracted intermediary, managed-care organization, or health plan that pays for hospital or medical bills instead of the individual.

Underinsured: Refers to people who have some type of health

insurance, such as catastrophic care, but not enough insurance to cover all their health care costs.

Uninsured: Individuals or groups with no or inadequate health insurance coverage.

Utilization review: Evaluation of the necessity, appropriateness, and efficiency of the use of health care services, procedures, and facilities.

Health Maintenance Organizations

Health maintenance organizations (HMOs) deliver comprehensive health maintenance and treatment services to a group of enrolled individuals who prepay a fixed fee. The HMO accepts responsibility for the organization, financing, and delivery of health care services for all enrolled members. Several HMO models have evolved. The traditional HMO structure was a group or staff model, in which the HMO owns the hospital and employs a group of physicians and some specialty services to provide care to its members. Salaried providers generally spent all of their time serving members of the HMO, with no financial incentive to provide more care. An example is Kaiser Permanente Health Care System, which also has its own hospitals. A capitation method of payment is used in which a service provider receives a fixed amount per person (the capitation rate) and in turn agrees to provide all necessary care to each enrolled member. The employer pays a monthly or annual rate directly to the HMO. The individual may also have out-of-pocket expenses such as copayments. Staff models were described as *closed panel,* because employed physicians provided care only for members of the HMO. A community physician (physician or health care provider outside the HMO) could not care for a member of the HMO without prearrangement or authorization by the HMO. In an HMO plan, individuals pay low out-of-pocket expenses but must see a primary care provider first to be referred to a specialist. In a group-model HMO, the organization operates a health plan but contracts with

groups of physicians and hospitals to provide care. The medical group receives a share of the capitation rate received by the HMO, and the group agrees to provide all necessary physician services for the member. The physician can be paid by salary or on a fee-for-service basis. An independent practice association (IPA) HMO will be discussed later. For all types of HMOs, a fixed amount of money is available each year for health care, based on the capitation fee and the number of members enrolled (Barr, 2011). **Medicare** enrollees since the 1970s have been offered the option of enrolling in fee-for-service or HMO plans. An earlier health reform law, the Medicare Modernization Act of 2003, renamed the program to include Medicare Advantage plans.

Medicare Advantage Plans

Medicare Advantage plans are private health plans that are offered as an alternative to the traditional Medicare program and are available to 99% of Medicare beneficiaries. Those who enroll in a Medicare Advantage plan pay for the Part B premium (less any rebate if offered by the Medicare Advantage plan) and may pay an additional monthly Medicare Advantage plan premium for benefits and prescription drug coverage. The selected Medicare Advantage plan receives federal payments from Medicare for each enrollee. In 2015, 17 million Medicare beneficiaries were enrolled in 1 of more than 2000 plans offered that differ nationwide. Two-thirds of Medicare Advantage plans are HMOs. The KFF reports that the average beneficiary is able to choose from among 19 plans, with those living in metropolitan areas having a greater number of plans to choose from than those living in nonmetropolitan areas as the number of firms offering plans differs by location. Most Medicare Advantage plans (87% of plans in 2016) offer prescription drug coverage (MA-PD). Medicare beneficiaries who enroll in Medicare Advantage plans often have extra benefits such as vision, hearing, dental, and wellness plans when compared with those in the traditional Medicare program. In 2015 the average monthly premium for a Medicare Advantage plan HMO in 2015 was $39, for regional preferred provider organizations (PPOs)

was $75.00, and for local PPOs was $79.00. Some Medicare Advantage plans have no additional monthly premium other than Medicare Part B premium and are called "zero premium plans." It is projected that approximately 80% of all Medicare beneficiaries will have access to some type of a zero-premium plan by the year 2016 which limits some out-of-pocket expenses as reported by the KFF. Members in the traditional Medicare program have no out-of-pocket limits under Medicare Part A and Part B, and thus have unlimited financial liability. Those who enroll in a Medicare Advantage plan have out-of-pocket expenses for services covered in Part A and Part B limited to no more than $6700 for services received from in-network providers. The out-of-pocket expense amount listed does not include expenses for prescription drugs or extra benefits not covered by the plan. The quality of a Medicare Advantage plan is rated at the contract level by a star system (one to five) with one star representing a poor rating, three stars representing an average rating, and five stars representing excellent performance. The CMS has assigned a star rating since 2012, and plans with high ratings receive higher rebate amounts. For example, plans rated with four or more stars receive 5% bonuses. Bonus percentages are doubled in some counties. Medicare members must select and enroll in a plan during the open enrollment period, but if a plan is rated five star, beneficiaries can enroll in those plans year round (KFF, 2015b). Selecting a Medicare Advantage plan that best fits the needs of an individual can be very confusing, especially since plan benefits change from year to year and the health care needs of an individual may change as well.

Independent Practice Associations

Independent practice associations (IPAs) are organizations composed of independent physicians in solo or group practices who provide health care services to members of an HMO in their private offices, eliminating the expense of the staff model HMO, which furnished and owned the facility in which care was provided. The HMO for a fee-for-service or a prepaid price can purchase hospital care and specialty services not within the IPA. Physicians in an IPA

contract may be restricted to caring only for members enrolled in the IPA, but some contracts may allow providers to care for nonmembers as well. Other variations of the staff model and IPAs exist. In a group practice model, an HMO contracts with all physicians and specialists needed by the HMO enrollees, but physicians remain independent. Some contracts are exclusive, requiring physicians to restrict care to members of an individual HMO, and other variations allow physicians to care for members outside the HMO. In a network model, HMOs contract with individual physicians and with physician groups for both primary and specialty services. The HMO maintains control over fee arrangements (Barr, 2011).

Accountable Care Organizations

Accountable care organizations (ACOs) are key components in the ACA. ACOs in structure will be similar to traditional HMOs that are responsible for the quality and cost of care delivered to a defined population. An organization, either public or private, would be created that has a group of primary care physicians, providers, specialists, and hospitalist to provide health care in a local area. Physicians would accept the responsibility for the quality of care provided and the overall costs of delivering care to a defined population of individuals (Kovner & Knickman, 2015). In the ACA, ACOs will become an important part of Medicare reform. An ACO that serves a person in the Medicare system will be required to be composed of physicians, specialists, and hospitals that manage the health needs of a minimum number of Medicare beneficiaries for a specified period. ACOs will have financial incentives in place to encourage providers to keep health care costs low by not ordering unnecessary tests and procedures, and by focusing on prevention and treatment of individuals with chronic disease out of the hospital. Performance and savings benchmarks would be in place with a financial reward system as well as penalties.

Concierge Medical Practices (Retainer Medicine)

According to an Accountability Office (2005) report to congressional committees and Concierge Medicine Today, **concierge care** is a newer model for providing primary care in a medical practice in which physicians charge individuals a membership fee averaging $1500 to $5500 per year in return for enhanced health care services or amenities. Approximately 12,000 physicians operate concierge-type practices, and 80% of concierge physicians accept insurance, whereas others are cash only. Amenities most often include same-day or next-day appointments for nonurgent care, 24-hour telephone/e-mail access to the physician, and routine periodic preventive examinations. Some concierge physicians do not accept insurance, but others report billing a person's health insurance for covered services and Medicare. Individuals electing to join a concierge practice are encouraged to have health care insurance for services used outside the practice, such as specialty care, complex diagnostics, and hospitalization. Although there is wide variation in the amenities offered, no–waiting time office visits, 24-hour access to physicians via cell phones and e-mail, same-day office appointments, and even the possibility of a house call serve as attractive incentives for individuals and families. Some medical issues can be handled digitally, with patient assessments made by phone images and e-mails, avoiding the need for an office visit. Physicians who provide concierge care typically care for fewer people (600 or fewer, compared with an average load of 2500 plus), allowing physicians more time to spend with each person and to provide expanded preventive services and practice amenities that are not available in a traditional practice. Concierge physicians typically treats 6 to 10 individuals per day, and according to Concierge Medicine Today's physician compensation report for 2014, earn on average the same salary as physicians in traditional medical offices. Fifty-seven percent of concierge physicians earn $300,000 or more and 23% earn $200,000 to $300,000 annually (Concierge Medicine Today, n.d.). Physician salaries are predominately derived from membership fees, and for those that except insurance, from insurance companies. The average profile of an individual in a concierge practice is upper middle class (household earnings $125,000 to $250,000 annually), and

aged 50 years or older, although individuals and families with lower incomes may select concierge care for the convenience of high-quality holistic care. The number of concierge medical care practices is growing slowly, and they are not available in all areas, but there are those who oppose a model of care that favors the affluent receiving high-quality care. The shortages of primary care providers in traditional practices limits access to primary care at a time when the ACA has increased the number of insured individuals and families. If a physician leaves a traditional practice setting and begins a concierge practice, previous patients must find a new provider, which is problematic in areas where there is a shortage of providers. Physicians who choose concierge practice over traditional primary care offices report more time off, less paperwork, need for fewer office staff, and overall higher professional satisfaction as they are able to spend more time with patients. Additional time allows personalized service and the ability to provide holistic care. In turn, cost savings may be realized with a reduction in chronic disease or complications of disease, reduction in the need for emergency department visits, and reduction in the need for hospitalization and specialty visits (Concierge Medicine Today, n.d.).

Hospitalist Movement

Responding to the same impetus that spurred managed care in outpatient settings, **hospitalist** programs—supported by HMOs, hospitals, and medical groups—were formed to control hospital costs without compromising quality or satisfaction with client care. Hospitalists are physicians or APNs whose professional focus is managing the comprehensive care of the hospitalized individual, providing direct inpatient primary, critical, and consultative care 24 hours a day. Hospitalists engage in clinical care, teaching, research, and leadership in the field of hospital medicine and meeting the needs of hospitalized patients with acute and chronic complex diseases. Hospitalists enhance the quality and safety of care of a patient within the hospital setting and the safe transitioning of care from the acute care hospital setting to post–acute care facilities or home. Studies have

found that hospitals with a hospitalist model program have improved both the quality and the safety of care, with reduced lengths of stay, readmission rates, mortality rates, and complication rates, with efficient use of hospital and health care resources (Society of Hospital Medicine, n.d.).

Point-of-Service Plans

Point-of-service (POS) plans evolved in response to concern about restrictions of consumer choice in selecting providers and services. POS plans allow members, for an additional fee and higher copayment, to use providers outside the individual HMO network. Members can choose to pay for this enhanced POS or stay within the HMO network for reduced copayments. If the individual receives care from a physician or hospital not within the list of providers or hospitals, the person pays a substantial portion of the cost of care, usually as out-of-pocket expenses.

High-Deductible Health Insurance Plans

High-deductible health insurance plans (HDHPs) are structured similarly to traditional managed care plans and fee-for-service plans but have a very high annual out-of-pocket deductibles of $1000 or greater for individual coverage. A growing number of employers are offering these types of plans, and for those individuals who are generally healthy, the low monthly premium is an attractive option compared with the cost of other types of employer insurance plans. Plans usually have a set annual out-of-pocket limit. Attached to these plans, an employer can offer **health savings accounts (HSAs)** or savings options. Typically, an employer will make quarterly or annual deposits into the individual's health savings account, and the employee can elect to have additional funds withheld on a pretax basis to be deposited into the account, up to the annual Internal Revenue Service maximum. Individuals can withdraw money from the account at any age for health-related expenditures. The remaining money in the fund can be withdrawn at retirement without penalty.

Most high-deductible health insurance plans are paired with in-network providers for additional savings. Some plans allow preventive services (e.g., adult physical examinations, cancer screenings, mammograms, routine gynecological visits, and well-child care) for no charge if an in-network provider is used. Office visits for sickness, laboratory tests, emergency and urgent care, and hospitalizations are covered all or in part after the deductible has been met. Because the annual out-of-pocket expenses are high, until the deductible has been met, individuals may decide to delay or not seek health care.

Preferred Provider Organizations

Preferred provider organizations (PPOs) are a type of managed care plan in the private sector that has a preselected list of providers who have agreed to provide health services for those individuals enrolled in the plan. Contracted providers in the PPO agree to deliver services to members for a fee-for-service prenegotiated rate, which is usually discounted. To control costs, members must receive care exclusively from providers within the PPO or incur additional costs if a provider outside the PPO is used. Individuals are typically required to pay a copayment each time services are given. If an individual chooses to see a provider outside the PPO, he or she will pay additional costs. To control costs, the provider must receive preauthorization from the PPO for a member to be hospitalized or for some procedures or tests, and second opinions are usually required before major procedures or surgical operations are performed.

The KFF conducts an annual survey that reveals the distribution of the health plan type for individuals enrolled in employer health plans. Some employers, often those that are large, offer a variety of health plans to their employees. The distribution of health plan enrollment for covered workers reveals that 52% of workers have been enrolled in employer PPO plans, 24% of covered workers are enrolled in a high-deductible health insurance plan with a savings option, 14% are enrolled in an HMO, and 10% are enrolled in a POS plan, with 1% in a conventional or indemnity plan. POS plans were more popular among

small firms, and PPOs were more popular for covered workers at large firms (KFF, 2015b).

Public Sector

The public sector contains official and voluntary public health agencies operating at the local, state, federal, and international levels. Before 1900, public health was concerned with problems related to environmental risks and infectious diseases. After the 1900s the public health agenda expanded to address the needs of children and mothers. By midcentury, treating chronic disease had also been added to the agenda. As the century progressed, public health issues came to include substance abuse, mental illness, teenage pregnancy, long-term care, epidemics of violence and/or HIV/AIDS, and most recently bioterrorism and disaster preparedness (Nies & McEwen, 2014).

Source of Power

The US Constitution is based on the sharing of sovereign power between federal and state governments. The powers of the federal government in relation to health are not delineated specifically in the US Constitution; they are derived from its authority to tax and to spend for the general welfare and from powers delegated to it by the states. The state governor or legislature usually appoints a health commissioner or secretary of health, who directs the health agency (usually the public health department) to protect citizens from communicable diseases and environmental hazards from waste, water, and food (Nies & McEwen, 2014). State health authority is based also on the Tenth Amendment, which reserves for the states, or for the people, those powers not delegated to the federal government by the US Constitution. The states then use their powers to create local governments and delegate authority to them in health matters. The US Public Health Service falls within the larger USDHHS. Box 3-6 lists the federal Public Health Service agencies within the USDHHS.

Box 3-6

The Department of Health and Human Services

The Federal Public Health Service Agencies

Agency for Healthcare Research and Quality: Federal agency whose mission is to improve the quality, safety, efficiency, and effectiveness of health care for all Americans. Supports research with grants and funding.

Centers for Disease Control and Prevention (CDC): Working with states, it provides a system of health surveillance to monitor and prevent outbreaks of disease.

Centers for Medicare & Medicaid Services (CMS): Federal agency that runs the Medicare program and works with states to run the Medicaid program.

Children's Health Insurance Program (CHIP) (Title XIX and Title XXI): CHIP is a joint federal and state program that provides insurance for families who do not have health insurance and are not eligible for Medicaid.

Food and Drug Administration (FDA): Federal agency responsible for protecting the public, which includes ensuring foods are safe, wholesome, sanitary, and properly labeled; guaranteeing human and veterinary drugs, vaccines, and other biological products and medical devices intended for human use are safe and effective; protecting the public from electronic product radiation; ensuring cosmetics and dietary supplements are safe and properly labeled; and regulating tobacco products.

Health Resources and Services Administration: Primary federal agency for improving access to health care services for people who are uninsured, or medically vulnerable.

Indian Health Service: Responsible for providing federal health services to American Indians and Alaska Natives (approximately 1.9 million individuals) who belong to 556 federally recognized tribes in 35 states.

National Institutes of Health (NIH): Provides leadership and direction

to programs designed to improve the health of the nation by conducting and supporting research. NIH funds basic, clinical, and translational biomedical and behavior research.

Office of the Inspector General: Office dedicated to combating fraud, waste, and abuse and to improving the efficiency of USDHHS programs. Provides oversight of Medicaid and Medicare, the CDC, the NIH, and the FDA

Substance Abuse and Mental Health Services Administration: Strengthens the nation's health care capacity to provide prevention, diagnosis, and treatment services for substance abuse and mental illness. Funds mental health and substance abuse prevention and treatment services

Influence of Political Philosophy

The prevailing political philosophy regarding societal health needs affects the relationship among federal, state, and local governments. Although the federal government gained power to promote health and welfare in the early 20th century by the passage of the Sixteenth Amendment (giving it the authority to levy federal taxes), states retained sovereign power because the resources were distributed at the state and local levels. Beginning in the 1930s, however, New Deal philosophy began to displace power from the state and local governments to the federal government. Passage of the Hill-Burton Act of 1946 and establishment of what is now known as the CDC increased the federal government's power over state and local affairs. The trend toward increased federal government involvement continued during the Kennedy-Johnson era, when the government focused on societal needs and health care to an unprecedented degree. During the Nixon-Ford era, the trend began to reverse as a New Federalism movement called for less federal encroachment into states' responsibilities and greater state and local responsibility. Clearly, the federal government's role varies according to political philosophy.

During the 1980s the Reagan administration supported free-market

competition among insurance plans, physicians, and hospitals to offer the best possible services with the lowest price. Reagan was adamant in his opposition to adopting national health insurance legislation for what he labeled “socialized medicine.” Reagan's procompetition policies supported a decrease in federal responsibility for health care, preferring to give states power by providing block grants and control at the state level.

During the Bush administration (1989–1993), incremental steps occurred in moving new legislation toward health care reform with a system of checks and balances in place so that no single political party controlled the White House, Senate, and House of Representatives. To avoid increasing taxes, President Bush proposed a system of tax deductions or tax credits to reduce the cost of private health insurance for families not covered by Medicaid or Medicare. Bush proposed the creation of large networks of small businesses to purchase group health insurance for their employees, voluntary measures to reduce insurance paperwork, encouragement of enrollment in HMOs, and legislation to reduce medical malpractice suits. Because of an economic recession, many workers employed by small businesses did not have employer health insurance plans, and these measures would have assisted in covering working families. However, congressional Democrats refused to support the proposed reform because it did not include an expansion of federal power with a plan for universal coverage or control over the growing cost of insurance premiums.

In 1993 the Clinton administration proposed the Health Security Act to achieve universal health care coverage in the United States by mandating that all employers provide health insurance for their employees and by giving small businesses and unemployed Americans subsidies with which to purchase insurance. The plan met severe opposition from the insurance industry and the business community. Mass media advertisements by these stakeholders questioned whether or not HMOs would provide choice and access to health care services. Large segments of the American public, especially the 80% who had employer-based private health insurance, began to fear being forced into HMOs, which would diminish their

choice of, access to, and quality of health care. The cost of a socialized, universal health care coverage system was estimated to reach trillion-dollar levels. The act was defeated in Congress, and a time of political caution followed, stalling any further movement toward universal health care. Small incremental health reform was passed such as the portability of health care coverage in 1996 (Health Insurance Portability and Accountability Act [HIPAA]), allowing persons to access health care throughout the United States, and the focus shifted to balancing the federal budget. Other incremental legislation included the passage of the Balanced Budget Act of 1997, which made significant reforms in Medicare, as well as the formation of a new public insurance program—the CHIP. CHIP is a partnership between the federal and state governments to provide health insurance to uninsured children whose families earn too much to qualify for Medicaid but are unable to afford private insurance coverage. Each state operates its own CHIP, and some states have renamed the program; for example, Georgia's program is called Peachcare and New Mexico named its program Mexikids. The federal funding of CHIP, however, requires the program to be renewed every few years. On April 16, 2015, President Obama signed into law H.R. 2, the Medicare Access and CHIP Reauthorization Act of 2015, which extends CHIP for 2 more years. In 2013, 8.1 million children were enrolled in CHIP.

Another major expansion in the role of the federal government occurred in 2003, when Congress passed the Medicare Prescription Drug Act Part D, and in 2007 when legislation was signed to continue funding CHIP programs. The biggest expansion of federal oversight since Medicare and Medicaid from the 1960s came when the ACA was signed into law in March of 2010 (Box 3-7: Research for Evidence-Based Practice).

Box 3-7

Research for Evidence-Based Practice

Connecting Eligible Immigrant Families to Health

Coverage and Care: Key Lessons From Outreach and Enrollment Workers, October 2011

The 2014 provisions of the ACA significantly expand insurance coverage for low- and moderate-income families through an expansion in Medicaid eligibility and by making tax credits available to help individuals and families purchase insurance coverage through new health care exchanges. In 2010, 38 million immigrants resided in the United States, which was 12.5% of the population. Seventeen million were naturalized citizens, and 21 million were noncitizens. Noncitizens include both lawfully present and undocumented individuals. There are many more individuals who live in families with mixed immigration status, such as a US-born child with one or both parents being noncitizens. In 2009, it was estimated that 5.6 million children were living with at least one noncitizen parent. Most natural citizens have employer or private insurance coverage, whereas noncitizens are nearly three times as likely to be uninsured compared with US citizens. Since 1996, lawfully residing noncitizens have not been eligible to enroll in Medicaid and CHIP during the first 5 years of their legally residing in the United States. Some states eliminated or reduced the 5-year requirement to care for pregnant women and children. Undocumented immigrants are individuals who are not in the United States legally and are prohibited from enrolling in Medicaid or purchasing coverage through health exchanges. Individuals who enter any country illegally are typically not entitled to receive health care or other benefits provided to their citizens and legal residents.

In 2014, when the ACA provision takes effect to expand coverage to individuals with incomes up to 133% of the federal poverty level ($14,484 for an individual or $24,645 for a family of three in 2011), many more individuals will be eligible for Medicaid and individuals with incomes of up to 400% of the federal poverty level ($43,560 for individuals or $74,120 for a family of three in 2011) will be able to buy coverage through new health benefit exchanges using tax credits to help pay for the coverage. Lawfully residing immigrant families are

expected to significantly benefit from the coverage expansion. To realize the benefit of the health reform law, enrolling immigrant families will be key and targeted outreach efforts will need to be employed. Immigrant families face numerous challenges in accessing needed care because of limited transportation options and language barriers. Immigrant families may also experience fear and confusion in navigating the health care system and being cared for by a primary care provider who may not have the capacity to provide culturally and linguistically appropriate services.

Methodology

To gain increased insight into barriers to coverage and care facing eligible immigrants, and to develop successful strategies to overcome these barriers, Health Outreach Partners and the Kaiser Commission on Medicaid and the Uninsured hosted focus group discussions with outreach and enrollment professionals who serve immigrant communities. Thirty-five professionals participated in one of four focus groups, with one focus group held in Florida, one focus group held in Washington, DC, and two focus groups held in California. With use of a structured interview guide, participants were asked questions concerning barriers to coverage, strategies they use to overcome these barriers, and perceptions of the potential impact of the coverage expansion on immigrant communities. Participants gave their consent for the interviews to be recorded and transcribed. Data were analyzed by qualitative software and supplemented with relevant research and data from a recent farm worker health outreach national needs assessment report. Participants were individuals who provide outreach and enrollment assistance in immigrant communities.

Successful strategies to overcome barriers to coverage and care were revealed, which included:

- use of trusted community organizations and individuals to provide outreach and enrollment assistance;

- providing direct one-on-one assistance from individuals with a

shared background or experience;

- educating families about coverage options and the enrollment process;
- providing families with a list of required documents and identifying alternative options;
- offering both English and Spanish forms to document income;
- providing cards that families can present to request translation assistance;
- maintaining contact over time to assist families with renewal.

Recommendations and Conclusions

Addressing barriers that immigrant families face will require significant changes in processes and systems as well as a cultural shift among local eligibility offices that is focused on promoting coverage. The findings support the need both to provide outreach and enrollment assistance that meets the needs of immigrant families and to offer strengthening messages to dispel fears among the immigrant community.

Current Health Policy

On March 23, 2010, President Obama signed into law the ACA. The goals of the massive health care reform act were to dramatically reduce the number of uninsured Americans, pay for coverage without adding to the national debt, slow the rising cost of health care, and encourage a more efficient health care system (Kovner & Knickman, 2015). When first elected to office, President Obama pushed for health care reform and gained the support from a strong Democratic

majority in both the House of Representatives and the Senate. Before it became law, bitter debates between Democratic and Republican members of the House of Representatives and the Senate occurred. Democratic control of the Senate and the House of Representatives allowed the bills to be quickly voted out of committee and introduced to the floors. In December 2009, the Senate bill passed with the partisan support of all Democrats. No Republican senators voted in favor of the bill. In March 2010 the bill came to a vote in the House of Representatives. This time there was bipartisan support against the bill, with 178 Republicans and 34 Democrats voting against it. The bill passed by seven votes (219 vs. 212), and 2 days later the health reform act of 2010 was signed into law, and an amended version was passed in May 2010 (Office of the Legislative Council, 2010). The 974-page document is long and complex, with many provisions and a timeline for incremental sections to be enacted, with most of the provisions taking place by 2014 (see http://healthreform.kff.org/timeline.aspx for a timeline of detailed provisions by year). See Box 3-8 for a section-by-section title list of the ACA.

Future Health Policy

Historically there has been a lack of consensus among the major political parties and stakeholders regarding health care reform. Since the ACA became law in March 2010, a number of states, individuals, and other organizations have filed actions in state and federal courts challenging the constitutionality of the law. The federal Supreme Court determined the constitutionality of the various provisions of this law in March 2012. Because the implementation of the law will occur over time (from 2010 to 2018), later provisions may also be met with legal opposition at the state and federal levels, which may result in amendments to the provisions. The timeline for implementation of the many provisions of the ACA began in 2010 under President Obama's term. Since full implementation was not slated to occur until 2018, and the Democrats lost federal political control with the November 2016 election, Republican control under the direction of

President Trump will allow new opportunities to modify, amend, or repeal all or parts of the ACA. Since the executive branch of the federal government holds the power to change health care laws that state governments must then enact, substantial effort is needed in policy reform to prioritize both issues of access and cost containment. As future advances in science unfold, how resources are used to improve the quality and safety of patient-centered care will require ongoing adjustments in the provision and financing of health care (Box 3-9).

Box 3-9

Regulation of Quality and Safety of Medical Devices: Proposed Ban on the Use of Powdered Gloves

On May 28, 1976, the Federal Food, Drug, and Cosmetic Act became law, which authorized the United States Food and Drug Administration (FDA) to ban by regulation any device intended for human use on the basis of all available data if the device presented a "substantial deception" or an "unreasonable or substantial risk of illness or injury" which could not be, or has not been, corrected or eliminated by labeling or a change in labeling. The FDA protects the health of the public by monitoring reports of adverse events and other problems with medical devices. The FDA communicates safety concerns by alerting medical professionals and the public after analyzing the risks and benefits the devices poses to individuals. Information updates on recalls, current bans, and proposed bans can be found on the FDA website. On March 22, 2016, the FDA proposed a ban on powdered surgeon's gloves, powdered patient examination gloves, and absorbable powder for lubricating a surgeon's glove. Various types of powder have been added to gloves since the 1930s so wearers could don the gloves more easily. The proposed ban does not include powder intended for use on other medical devices or condoms. Before proposing the ban, the FDA reviewed the risks from the use of powder to both patients and users, including acute airway

inflammation because of inhalation of the powder particles; hypersensitivity and allergic reactions; and risk of granuloma and adhesion formation to patients and care workers if internal tissue is exposed to powder. Once a ban is proposed, a period is allotted for comment before a final determination is made. As nonpowdered gloves are readily available and offer the same protection, the FDA expects if a powdered glove ban is implemented, reduction of adverse effects to both patients and health care workers will save $26.6 million to $29.3 million dollars annually. At that time, all unused powdered gloves will be required to be pulled from use and disposed of.

Banned Devices; proposal to ban powdered surgeon's gloves, powdered patient examination gloves, and absorbable powder for lubricating a surgeon's glove. https://www.federalregister.gov/articles/2016/03/22/2016-06360/banned-devices-proposal.

Nursing's Role in Leading Change—2010 Recommendations of the Institute of Medicine

Report on the future of nursing.

The Robert Wood Johnson Foundation and the IOM in 2008 launched a 2-year initiative to respond to the need to assess and transform the nursing profession. The IOM appointed the committee on the Robert Wood Johnson Foundation Initiative on the Future of Nursing and charged the committee with producing a report that would make recommendations for an action-oriented blueprint for nursing's future. The nursing workforce, composed of more than 3 million nurses, is the largest segment of the nation's health care workforce. The IOM recognized that nurses play a key role in helping realize the objectives set forth in the 2010 ACA but a number of barriers exist that prevent nurses from being able to respond effectively to rapidly changing health care settings and an evolving health care system. The committee developed the following four key messages and seven recommendations (IOM, 2010):

- Nurses practice to the full extent of their education and training.
- Nurses achieve higher levels of education and training through an improved education system that promotes seamless academic progression.
- Nurses should be full partners, with physicians and other health care professionals, in redesigning health care in the United States.
- Effective workforce planning and policy-making require better data collection and an improved information infrastructure.

For the IOM's report on the future of nursing recommendations, see Box 3-10: Innovative Practice. As discussed earlier, the IOM of the National Academies of Science, Engineering, and Medicine was renamed the Health and Medicine Division (HMD) in March 2016. The newly named division will expand the range of health matters analyzed to provide health policy advice to the nation's leaders (National Academies of Sciences, Engineering, and Medicine, 2016).

Box 3-10

Innovative Practice

Institute of Medicine's October 5, 2010 Report on the Future of Nursing Recommendations

Recommendation 1: Remove scope-of-practice barriers. Advanced practice registered nurses should be able to practice to the full extent of their education and training.

Recommendation 2: Expand opportunities for nurses to lead and diffuse collaborative improvement efforts. Private and public funders, health care organizations, nursing education programs, and nursing associations should expand opportunities for nurses to lead and manage collaborative efforts with physicians and other members of the health care team to conduct research and to redesign and improve practice environments and health systems. These entities should also provide opportunities for nurses to diffuse successful practices.

Recommendation 3: Implement nurse residency programs. State boards of nursing, accrediting bodies, the federal government, and health care organizations should take actions to support nurses' completion of a transition-to-practice program (nurse residency) after they have completed a pre-licensure or advanced practice degree program or when they are transitioning into new clinical practice areas.

Recommendation 4: Increase the proportion of nurses with a baccalaureate degree to 80% by 2020. Academic nurse leaders across all schools of nursing should work together to increase the proportion of nurses with a baccalaureate degree from 50% to 80% by 2020. These leaders should partner with education accrediting bodies, private and public funders, and employers to ensure funding, monitor progress, and increase the diversity of students to create a workforce prepared to meet the demands of diverse populations across the life span.

Recommendation 5: Double the number of nurses with a doctorate by 2020.

Recommendation 6: Ensure that nurses engage in lifelong learning.

Recommendation 7: Prepare and enable nurses to lead change to advance health.

Recommendation 8: Build an infrastructure for the collection and analysis of interprofessional health care workforce data.

Source Institute of Medicine. (2010). The future of nursing: Leading change, advancing health. http://www.iom.edu/Reports/2010/The-Future-of-Nursing-Leading-Change-Advancing-Health.aspx.

Official Agencies

Official agencies are tax supported and therefore accountable to the citizens through elected or appointed officials or boards. The purpose and duties of official agencies are prescribed or mandated by law. This discussion is from the perspective of the individual gaining knowledge of or access to the health care system.

Local level.

The health department of a town, city, county, township, or district is the local health unit and is usually the first line of access and health responsibility for the population that it serves. The mayor, the board of health, or some other executive governing body appoints the chief administrator, the health officer. The local health department's role and functions usually center on providing direct services to the public and depend on the state mandate and community resources. Local governments, but usually not health departments, have the responsibility to provide general health care services for the poor.

State level.

Public health services are organized by each state, with wide variation from one state to another. The chief administrator is usually a state health officer or commissioner appointed by the governor. One agency, typically the state health department, performs the primary responsibilities in policy, planning, and coordination of programs and services for local units under its jurisdiction.

Federal level.

The federal government assumes overall responsibility for the health protection of its citizens. Although all three branches of the government make health-related decisions, the major policy decisions are made by the president and the president's staff (executive branch) and by Congress (legislative branch). These two branches determine health policy. Once policy has been determined, other government agencies are responsible for oversight to ensure implementation.

The USDHHS, the main federal body concerned with the health of the nation, consists of a number of separate operating agencies (see Box 3-6). Under each of the federal public health service agencies listed there are numerous other departments. USDHHS agencies that relate directly to nursing include the Health Resources and Services Administration and the National Institutes of Health (NIH). The Bureau of Health Professions, within the Health Resources and Services Administration, contains a division of nursing, which is a source for nursing education and training grants. The National

Institute of Nursing Research within the NIH funds nursing research, including health-promotion and illness-prevention studies.

Chief nursing officer.

The chief nursing officer (CNO) serves in the US Public Health Service and leads the Commissioned Corps of the US Public Health Service (Corps) Nurse Professional Affairs. The CNO advises the Office of the Surgeon General and the USDHHS on the recruitment, assignment, deployment, retention, and career development of Corps nurse professionals. As the deputy associate administrator in the HIV/AIDS Bureau, Health Resources and Service Administration, the CEO manages funds for services for uninsured and underserved persons with HIV and training for professionals. The CEO also assists in managing funds for global HIV/AIDS programs. The current CNO, Rear Admiral Sylvia Trent-Adams, was appointed in November 2009 (US Public Health Nursing Services, n.d.).

Federal emergency management agency.

The US Department of Homeland Security is another large branch of federal agencies with numerous offices, many of which have a connection with health care. Since 2003 the Federal Emergency Management Agency (FEMA) has been part of the US Department of Homeland Security. FEMA was established in 1979 by an executive order merging many separate disaster-related services into a single entity to assist states when a disaster overwhelms a state's capacity to respond. A disaster, as defined by FEMA, includes a hurricane, earthquake, tornado, flood, fire, hazardous spill, act of nature, or act of terrorism. The role of FEMA is to support citizens and first responders to build, sustain, and improve capacity to prepare for, protect against, respond to, recover from, and mitigate all hazards. Assistance is provided to individuals, communities, and states that are determined to be eligible. There are 10 regional FEMA offices located throughout the country, with headquarters in Washington, DC. In 2006 the Post-Katrina Emergency Management Reform Act created a "new FEMA" with an expanded mission and homeland security

preparedness responsibilities in the areas of recovery, response, and logistics. The response directorate, for example, provides coordinated federal operational and logistical disaster response capability needed to save and sustain lives, minimize suffering, and protect property in a timely manner in communities overwhelmed by a disaster (US Department of Homeland Security, n.d.).

Military health systems at the federal level.

The Military Health System (MHS) is a unique partnership of medical educators, medical researchers, health care providers, and support personnel who are prepared to respond anytime or anywhere with comprehensive medical capability to military operations, natural disasters, and humanitarian crises around the world and to ensure world-class health care is provided to all Department of Defense active duty members, retired US Military personnel, and their dependents.

The Department of Veterans Affairs (VA), an independent agency directly under the president, provides integrated health care services for veterans through the Department of Defense, which sponsors health care for military personnel on active duty. The VA uses an advanced computerized information system, which allows a person's medical record to be accessed in any VA site nationally, increasing efficiency in the provision of care. For active-duty service members and retirees of the seven uniformed services, their family members, survivors, and others who are registered in the defense enrollment eligibility reporting system, military health care is covered through the former Civilian Health and Medical Program of the VA. Following issues with delays in receiving medical care, the Veterans Choice Program went into effect in November 2014 and allows eligible veterans to receive care in their own community if their local VA medical facility is unable to schedule an appointment to be seen within a given time frame, or faces unusual or excessive burden in traveling to the nearest VA medical center based upon a number of given factors (VA, 2015). TRICARE is the health care program available to members of the National Guard and Reserves, retired

members, and their families.

Wounded warrior care.

When a soldier is severely injured, prolonged care and rehabilitation are often required before a decision can be made whether the soldier should remain on active duty. The MHS is responsible for providing clinical care to return service personnel to duty or to assist them in making the transition from MHS care to the VA health care system. Tremendous progress has been made in the rehabilitative care of injured combatants and coordination of MHS care with the VA health system.

Americans with disabilities.

Starting in 1992, health care providers, both as employers and as providers of public services, were required to comply with requirements of the Americans with Disabilities Act of 1990. The act is considered the most sweeping civil rights legislation since the Civil Rights Act of 1964. The two parts that apply most directly to health care providers are the prohibition of employment discrimination and the requirements for provision of services to people with disabilities. An example of health care provider accommodation is to install wheelchair lifts in shuttle bus systems. Despite their need for health promotion and disease prevention, individuals with disabilities face numerous problems gaining access to health-promotion programs and preventive services. The barriers are financial, social, physical, and logistical (USDHHS, 2015c).

In 1990, President George H. W. Bush signed the Patient Self-Determination Act, which took effect in December 1991. This law was designed to increase individual involvement in decisions about life-sustaining treatment, ensuring that advance directives for health care are available to physicians at the time that medical decisions are being made and ensuring that individuals who have not prepared such documents are aware of their legal rights. As a condition of Medicare and Medicaid payment, the Patient Self-Determination Act requires health care facilities to comply with the law. The ACA has several

provisions expanding the access requirements for services to people with disabilities.

Federal health information privacy law.

Developed by the USDHHS as part of the Health Insurance Portability and Accountability Act of 1996, federal privacy standards were enacted by Congress requiring new safeguards to protect the security and confidentiality of health information, including paper, electronic, and oral communications. Health plans, pharmacies, physicians, nurses, and other health care providers must have a written privacy procedure, provide employee training on the Health Insurance Portability and Accountability Act, and designate a privacy officer to ensure procedures are followed. The privacy law permits disclosures without individual authorization to public health authorities authorized by law to collect and receive information for the purpose of preventing or controlling disease, injury, or disability (USDHHS, n.d.a).

International level.

WHO, the United Nations' specialized agency for health as previously discussed, was established in 1948. WHO comprises members from more than 190 countries, and its core functions include giving worldwide guidance in the field of health; setting global standards for health; cooperating with governments in strengthening national health programs; and developing and transferring appropriate technology, information, and standards. The following is the six-point agenda of WHO: promoting development; fostering health security; strengthening health systems; harnessing research, information, and evidence; enhancing partnerships; and improving performance. In September 2015, a global plan of action for the next 15 years was developed with 17 Sustainable Development Goals and 169 targets. The new goals build upon what was not completed in the previous 15-year goals and seeks to meet the needs of the world's most disadvantaged people (women, children, poor), with the remaining overarching health goal of ensuring healthy lives and promoting well-

being for all ages. Emerging challenges were recognized, such as noncommunicable diseases (diabetes and heart disease) and changing social and environmental factors, such as sanitation, pollution, urbanization, and climate change (WHO, n.d.b).

Voluntary Agencies

The voluntary (not-for-profit) health movement, which began in 1882, stems from the goodwill and humanitarian concerns that are part of the nongovernmental, free enterprise heritage of the people of the United States. Nonprofit entities that maintain a tax-free status are often powerful forces in the health field, voluntary agencies, foundations, and professional associations. The tax-free status of these organizations is challenged at times on the basis of charge that some of them serve only a limited population. Voluntary agencies are influential in promoting health affairs and research agendas at the national policy level and often have significant influence on health legislation. Their prominent role was demonstrated by the American Cancer Society's early mass media announcements about the health hazards of smoking. An example of another voluntary agency is the Alzheimer's Association, which has local chapters that provide resources for families, including publications, services, respite for the caregiver, and support groups for individuals and families.

Philanthropic foundations provide valuable stimulation to the health field and operate under fewer constraints than do other sources in supporting research or training projects. Nurses interested in research or advanced clinical study that relates to the special interests of voluntary agencies or foundations may find grant monies available to support their work. For example, the John A. Hartford Foundation is a foundation established in 1929 and supports efforts to improve health care for older Americans. Recently, the trustees of this foundation awarded a $5 million, 5-year grant to create the John A. Hartford Foundation Institute for Geriatric Nursing at New York University, which promotes initiatives to improve care of older adults and training projects to prepare faculty to teach care of older adults in baccalaureate nursing programs. The institute has also raised the

profile of geriatric nursing by creating nationally recognized awards for excellence in research and practice (John A. Hartford Foundation, 2012). Professional associations, organized at the national level with state and local branches, are powerful political forces. Nurses can support their professional organizations in influencing the direction of health policy through membership and active participation.

The American Red Cross.

The American Red Cross is a well-known volunteer-led humanitarian organization that is officially sanctioned by the federal government as a congressional charter, meaning it is not supervised by the government because it is not a governmental agency, but is recognized officially. Founded in 1881 by Clara Barton, the International Red Cross aids victims of war and natural disasters throughout the world. There are more than 700 local American Red Cross chapters in the United States, with more than 500,000 volunteers and 35,000 employees. The American Red Cross responds both to small local emergencies to help victims (such as in the case of a house fire) and to large natural disasters (such as hurricanes and earthquakes). The Red Cross is the largest supplier of blood and blood products in the United States, helps thousands of US service members separated from their families maintain communication, and offers communities a range of health and safety courses. The global network of national societies relies on public donations of money, time, and blood. Local Red Cross opportunities exist, including the donation of blood and assistance with blood drives and other volunteer activities (American Red Cross, n.d.).

Financing Health Care

Costs

The health care industry is the largest service industry in the United States today and the most powerful employer in the nation. The Bureau of Labor Statistics projects health care occupations will grow by 19% from 2014 to 2024, adding 2.3 million jobs (US Department of Labor, 2015b). National health expenditures in the United States were greater than those in any other country, with $3.2 trillion spent in 2015 (or $9990 per person), a marked increase from the $1.9 trillion spent in 2004. In 2015 health spending consumed 17.8% of the GDP and is projected to grow at an average rate of 5.8% per year from 2015 to 2025, and the health-share GDP is expected to rise to 20.1% by 2025. In 2014, the breakdown of national health spending was as follows: hospital expenditures $971.8 billion, Medicare spending in 2014 grew by 5.5% to $618.7 billion or 20% of the budget, Medicaid spending, which accounts for 16% of national health expenditures, grew by 11% to $495.8 billion, private health insurance spending was $991.0 billion or 33% of national health expenditures, out-of-pocket expenditures grew to $329.8 billion, or 11% of national health expenditures, physician and clinical service expenditures grew by 4.6% to $603.7 billion, and prescription drug spending increased by 12.2% to $297.7 billion. The trend in health care spending increases was projected to be 5.5% in 2015 and peak at 6.3% in 2020. In 2010 the per capita expenditure for health care (amount of money on average spent on each individual in the United States) was for the 65 years and older population $18,424, which is five times higher than the amount spent per child ($3628), and three times higher than the spending per working-age person ($6125), or on average $8402, per capita, the highest of all countries. Thirty-four percent of spending in 2010 was on older adults, who are the smallest group, or 13% of the population (CMS, 2015a, 2017). Canada, for example, which borders the United States, is reported to spend just more than $4000 per person, which is half of what the United States spends. Many other countries spend far

less per capita, yet life expectancy is greater and infant mortality rates are lower. In addition to the United States spending more health care dollars per person than any other country, the rate of growth in per capita health expenditure in the United States is much steeper than that of other countries. The graphical representation in Figure 3-4 illustrates that in 1970 the per capita expenditure was $356, or 7% of GDP, and rapidly increased in each decade. The United States has outpaced all other countries and spends the most health care dollars per capita. Another measure of comparison is the amount of money a country devotes to health care in terms of GDP. Over time, the United States again outpaces the other nations in the percentage of GDP devoted to health care. In 2010, of the 305.2 million Americans, 49% had employer-based health insurance, 5% had private health insurance, 12% were enrolled in Medicare, 17% were enrolled in Medicaid, and 16% of the population were uninsured (Figure 3-5). A major focus of the ACA is aimed at reducing the number of uninsured Americans. These figures and expenditures, although numerous, introduce the topic of health care financing.

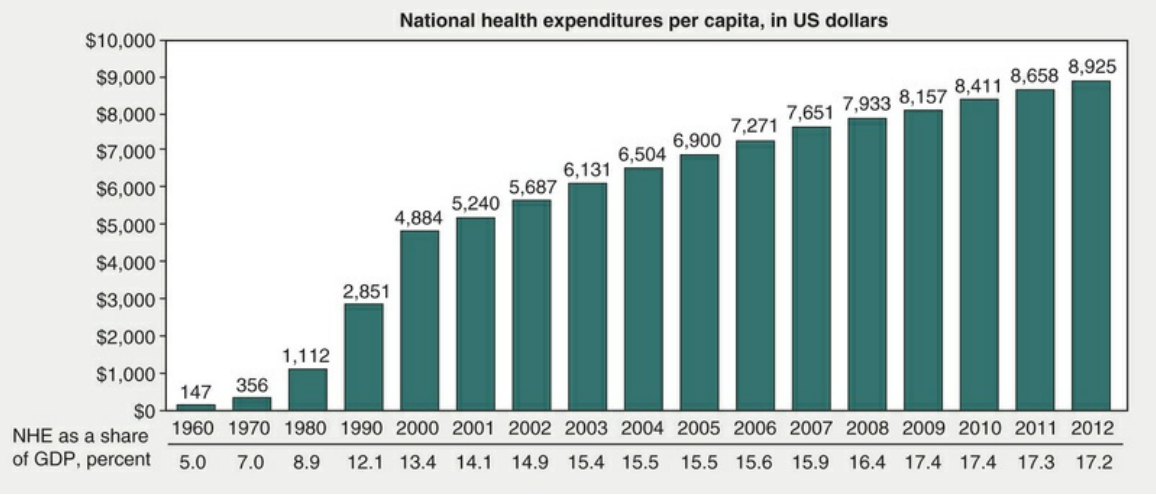

FIGURE 3-4 National health expenditures per capita. *GDP*, Gross domestic product; *NHE*, national health expenditure.

by type of service and source of funds; file nhe12.zip]; GDP data from Bureau of Economic Analysis at http://bea.gov/national/index.htm#gdp [file gdplev.xlx]. Slide available from the Kaiser Family Foundation. http://kff.org/Kaiser-slides/.)

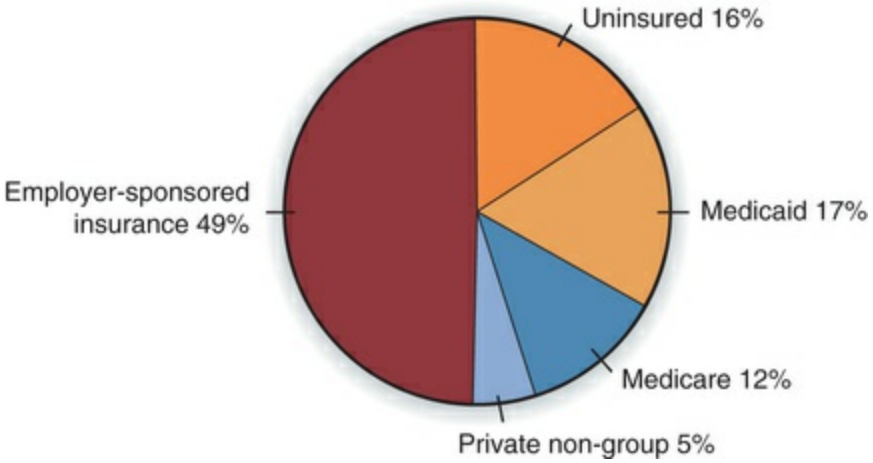

FIGURE 3-5 Total expenditure on health care as a share of gross domestic product. Medicaid also includes other public programs: Children's Health Insurance Program, other state programs, military-related coverage. The numbers may not add up to 100% because of rounding. (From Health insurance coverage: KCMU/Urban Institute analysis of 2011 data from 2012 ASEC Supplement to the CPS. Health expenditures: KFF calculations using 2011 NHE data from CMS, Office of the Actuary. Found in Kaiser Commission on Medicaid and the Uninsured: Medicaid and its Role in State/Federal Budgets & Health Reform, April 2013. https://kaiserfamilyfoundation.files.wordpress.com/2013/04/8162-03.pdf.)

Health care analysts predict the accelerations in health care costs will continue, putting pressure on public and private payers to finance them. Factors driving costs include general inflation; health care cost inflation; application of new and more advanced technologies; growth in the proportion of older adults; government financing of health care services, including long-term care; growth of prescription drug use and costs; misdistribution of health care providers and services; expansion of medical technology and specialty medicine; and other costs associated with providing health care. For example, diagnostic and therapeutic techniques—including computer-aided technology

and noninvasive imaging (such as magnetic resonance imaging), cardiac surgery, organ transplantation, joint replacements (particularly hips and knees)—enhance the capabilities of medicine while increasing costs.

A combination of the following factors results in hospitals having less time to offer prevention or health-promotion education to individuals: changes in hospital care and use of hospitalists, increased use of outpatient services, shorter inpatient stays, and increased time caring for chronic illness as opposed to acute illness. Moreover, workforce shortages, especially in nursing, increase the use of nonprofessional caregivers, and inadequate resources, reimbursement, and numbers of nurses may prevent health care professionals from offering the range of health promotion educational efforts requested in the *Healthy People 2020* objectives.

Sources

Ultimately, the American people pay for all health care costs. Money is transferred from consumer to provider by various mechanisms. The major sources are the government (federal, state, and local monies collected by taxes), third-party payment (private insurance), independent plans, and out-of-pocket support, which totaled $3.2 trillion in 2015. The CMS provide statistics on the source of the nation's health care dollars and the manner in which they are spent. In 2014 (Figure 3-6) the largest percentage of the nation's health care dollars came from private health insurance (33%), and 11% of health care costs were out-of-pocket payments made by consumers. The cost of Medicare accounted for 20% of the health care dollars and federal, state, and local Medicaid costs accounted for 16%. In all, some form of health insurance funds 73% of the nation's health care. Figure 3-7 provides a similar schematic but displays where health care dollars are spent. Almost one-third (32%) of health care dollars are spent on hospital care, 20% on physicians and clinical services, 10% on prescription drugs, 5% on nursing care facilities and continuing care retirement communities, 4% on dental care, 8% on administrative costs, and 14% on nonacute care. As discussed earlier, keeping

Americans healthy and out of the hospital would save a tremendous amount of money.

Employer Health Benefits

According to the employer health benefits survey's conducted by the KFF, the overall inflation rate of employer-sponsored health insurance for families has risen dramatically in the past decade. Between 1999 and 2015, health insurance premiums for individual and family coverage have risen significantly. The average employer-sponsored health insurance annual premium in 2015 was $6251 for individuals and $17,545 for family coverage. Since 1999 the average worker's contribution to family premiums has increased by 221%. The worker contribution for family coverage in 2001 was $1787 per year and in 2015 grew to $4955, whereas the employer contribution in 2001 was $7061 and jumped to $12,591 in 2015, for a total cost (does not include other costs associated with using the plan such as out-of-pocket expenses) of $17,545, making it difficult for both individuals and employers to pay for higher health care premiums (Figure 3-8). The cost for both single-coverage contributions of workers and employers in 2015 rose to $6251 (the employer contribution was $5179 and the individual worker's contribution was $1071). Again, this does not include the cost of using the benefits of the plan (KFF, 2015a). Most plans have additional out-of-pocket costs (co-payments) for use of the plan for office visits, laboratory testing, and other services, such as physical therapy. Almost all plans have some sort of prescription drug coverage but may limit coverage to certain medications (a formulary of what medications are covered or denied is usually part of a prescription plan). Some plans have a tiered list of medications with differing copayments. Generic medications (if available) generally have the least additional out-of-pocket cost and are listed in the lowest cost tier. Health care providers need to be aware of these variations between plans before prescribing medications, as out-of-pocket expenses may inhibit an individual from filling a prescription and following the prescribed medication plan.

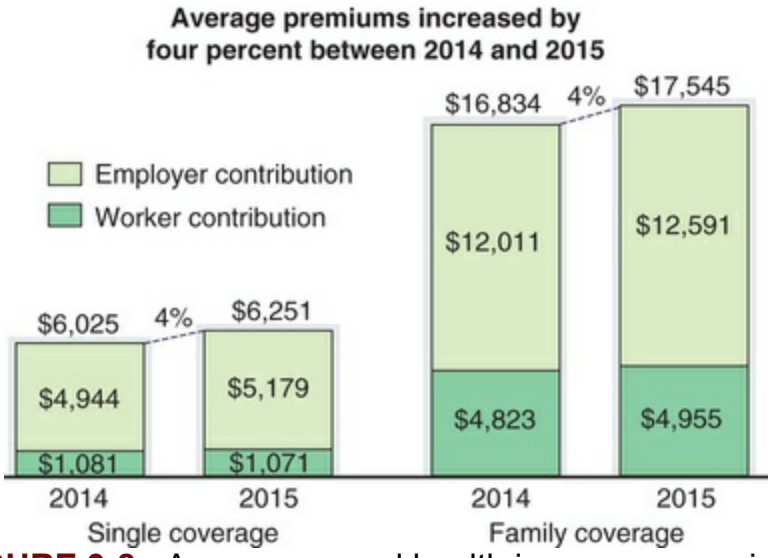

FIGURE 3-8 Average annual health insurance premiums and worker contributions for family coverage, 2014 to 2015.
(From Kaiser/HRET Survey of Employer-Sponsored Health Benefits, 2015. http://kff.org/report-section/ehbs-2015-section-one-cost-of-health-insurance.)

Federal and state **Medicaid** spending showed an increasing pattern similar to that discussed earlier in this chapter, with Medicaid spending reported to be $5.3 billion in 1970, $207.0 billion in 2000, $309.0 billion in 2004, $366.5 billion in 2009, and $475.91 billion in 2014 (Figure 3-9). As a cost-savings mechanism, by 2000, 55.8% of Medicaid recipients were enrolled in some form of managed care plan. Although costly, the Medicaid program finances health care for low-income children, adults, seniors, and people with disabilities. Children comprise 48% of individuals in the program but account for only 21% of the spending of Medicaid dollars, adults account for 27% of individuals in the program and 15% of expenditures, and elderly people account for 9% of those enrolled and 21% of expenditures. The blind or disabled individuals in the program, representing only 15% of those enrolled, accounted for 42% of Medicaid spending (Figure 3-10). The largest share of Medicaid monies, 71.2%, is spent on acute care and 24.9% is spent on individuals in long-term care (see Figure 3-10; KFF, 2014). Medicaid is a significant source of payment for long-term care, covering many nursing home residents. The ACA of 2010 has added millions of previously ineligible individuals younger than 65 years to state Medicaid plans, diminishing the number of

uninsured. Before ACA expansion, Medicaid eligibility was limited to specific low-income groups (elderly, people with disabilities, pregnant women, and children). For states that have opted to expand their Medicaid programs, individuals, including adults below 133% of the federal poverty level, are now eligible to enroll in their state Medicaid program. Previously, and still in states that have not expanded their Medicaid program, the threshold of 45% of the federal poverty line was required and adults (except those listed above) are not eligible. A state that agrees to expand its Medicaid program accepts additional federal funding to support the increase in the cost of running the program. As of May 2015, 28 states and the District of Columbia have expanded their Medicaid program (CMS, 2015b). This one measure has already decreased the number of uninsured Americans, by adding millions of newly eligible persons to the public insurance plan. States that have not expanded their Medicaid plan continue to have higher numbers of uninsured.

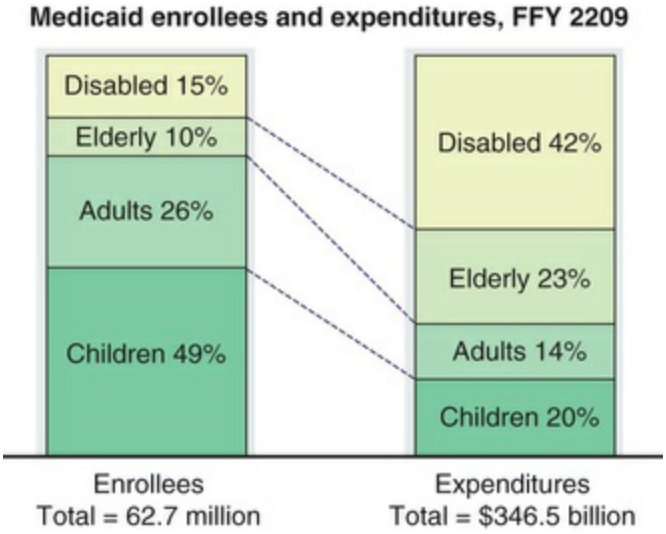

FIGURE 3-9 Medicaid enrollees and expenditures, fiscal year 2009. The sum of the pieces may not equal 100% because of rounding. (From KCMU/Urban Institute estimates based on federal FFY 2009 data from MSIS and CMS-64; 2012 MSIS FFY 2008 data were used for Pennsylvania, Utah, and Wisconsin, but adjusted to 2009 CMS-64. Slide available from the Kaiser Family Foundation. http://kff.org/Kaiser-slides/.)

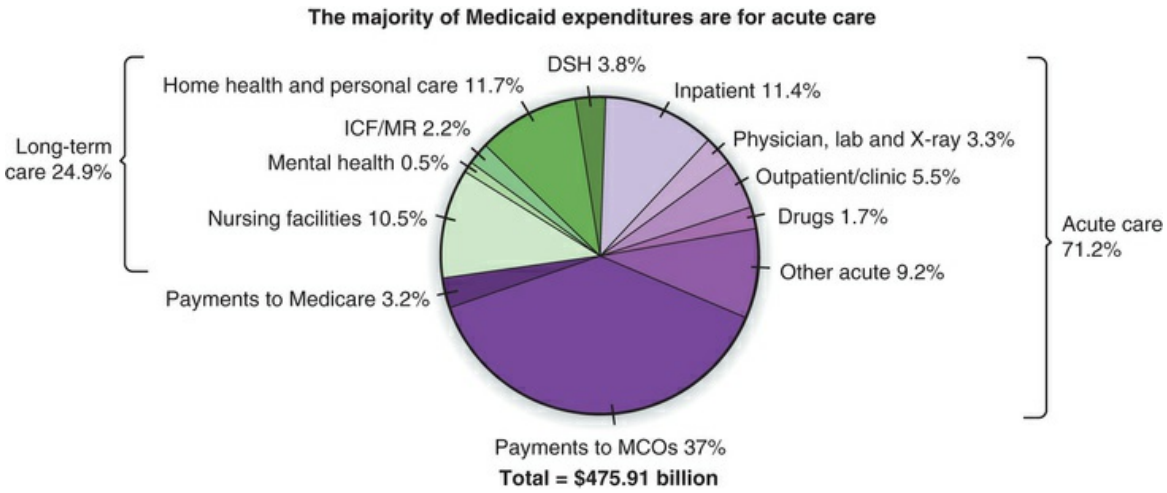

FIGURE 3-10 Most Medicaid expenditures are for acute care. By service, 2014. The total may not add up to 100% because of rounding. Excludes administrative spending, adjustments, and payments to the territories. (From Urban Institute estimates based on fiscal year 2014 data from CMS-64, prepared for the Kaiser Commission on Medicaid and the Uninsured. Slide available from the Kaiser Family Foundation. http://kff.org/Kaiser-slides/.)

Each state receives from the federal government a formula percentage of revenue to run a Medicaid program, leaving state budgets responsible for the remaining cost. Federal tax dollars must fund a minimum of 50% of a state's Medicaid cost. In 2014, 14 states—Alaska, California, Colorado, Connecticut, Illinois, Maryland, Massachusetts, Minnesota, New Hampshire, New Jersey, New York, Virginia, Washington, and Wyoming—were funded at the minimal level of 50%, whereas other states—for example, Mississippi (74.18%), West Virginia (72.62%), Kentucky (71.18%), Utah (70.99%), Arkansas (70.17%), and Idaho (70.23%)—received a much greater share of the cost of their Medicaid programs from the federal government (KFF, 2012). The greater the percentage of federal support, the less the state has to pay with state monies. For example, when a state receives only 50% of federal funding, the remaining 50% must be generated by state taxes. This is a tremendous burden on state residents. As the cost of the program increases and/or the number of persons enrolled in Medicaid increases, the taxpayers of the state must support the program, often through the raising of state, county, and local taxes.

Because Medicaid is an entitlement program, any one individual who meets Medicaid's eligibility requirements is entitled to receive benefits; therefore there is no way to cap the Medicaid budget at the federal or state level under current law. Many states have more lenient eligibility requirements than those set by the federal government and offer more health services than are mandated. The ACA has addressed some of the disparities by mandating essential health benefits that all insurance plans must cover. The ACA has provisions to provide financial incentives for states that qualify, to provide enhanced services to Medicaid recipients by increasing their federal matching funds. One way states have cut costs in Medicaid programs is to decrease provider payment rates and limit services. These practices can jeopardize provider participation (providers willing to care for individuals enrolled in a Medicaid program) and limit access to care for Medicaid recipients. Decreasing eligibility requirements for individuals and families so they qualify for Medicaid coverage is part of the solution to reduce the number of uninsured by adding more lower-income individuals and families to the Medicaid program. Since more individuals will now qualify for Medicaid if the state expands its Medicaid programs, individual states need to enhance or develop efficient user-friendly systems to facilitate the enrollment process. Health care delivery systems in each state have needed to adjust to accommodate the increased number of Medicaid enrollees in the provision of safe and efficient quality care. The ACA has some provisions to increase payments for primary care services provided by primary care providers because Medicaid provider reimbursement rates for services provided are typically much lower than other sources of payment.

Mechanisms

Payment

Although some health care providers and other professionals in the private sector are paid on a fee-for-service basis, by third-party private insurance, or by public-supported insurance, most health workers,

including nurses in institutional or community agencies and in the military, receive salaries or are paid by the hour regardless of the amount of care provided. Because nurses are salaried or paid by the hour, the separation of nursing costs from all other health-related costs is difficult. The cost of acute hospital nursing care is typically incorporated in the daily room and board charge in the acute care setting. Without documentation of specific nursing costs, validating the need for skilled nursing services is difficult.

In recent years, nurses and APNs have entered independent practice to provide direct services. The Bureau of Labor Statistics 2016 to 2017 report estimated in 2014 there were 170,400 jobs for APNs (122,050 nurse practitioners, 36,590 certified registered nurse anesthetists, and 5110 certified nurse midwives), with a projected need to increase the job numbers by 31% because of the effects of health care legislation, increased emphasis on preventive care, and need for health care of the aging population (US Department of Labor, 2015a).

Independent nursing practice may be viewed as a logical outgrowth of seeking higher levels of professionalism. The nurse practice acts of some states encourage nurses to use their knowledge more comprehensively than many agencies sanction. Although legislation in 1997 included the reimbursement of APNs by Medicare, not all plans and provider groups include these nurses as primary care practitioners. Clearly, the nursing practice roles and prescriptive authority of APNs differ between states. Incremental steps have been taken to advance the APN role at both the federal level and the state level. Some states have passed laws for nurse practitioners to practice and prescribe medications without physician oversight. The IOM's 2010 report titled *The Future of Nursing: Leading Change, Advancing Health* supports nurses practicing to the full extent of their education and training.

Alternative forms of payment for APNs are salary and capitation. The salary system involves a set amount for services provided in a specified time frame. This system provides the employee with a fixed nursing income that is protected from changes in supply and demand,

includes fringe benefits, and obviates fee collection problems. The salary system's flexibility makes it easier to fill unpopular jobs or jobs in underserved areas. The disadvantages of this system include a limit on income and constraints on schedules, vacations, and peer review. A nurse in a salaried position may not be able to earn overtime depending on the facility. Nurses who work beyond the scheduled hours are then uncompensated for additional time under a salary arrangement, which may lead to job dissatisfaction and burnout.

In the capitation system, such as in an HMO, each provider receives a flat annual fee for each participant regardless of how often services are used. Individuals who enroll in an HMO pay a fixed amount on a monthly basis whether or not they use the services; prepayment provides an incentive to provide efficient care. The objective is to keep people healthy to prevent costly services. Cost consciousness dictates that illness be treated as early as possible and in the most cost-effective setting. Capitation is simple to administer; no third-party insurance payments are present, and the HMO bears the risk of illness. Preventive primary care that avoids costly hospitalization keeps costs down, and the savings revert to the organization. On the negative side, individuals who make frequent or unnecessary visits to a provider in an HMO decrease the efficiency of the system.

Cost Containment

The government's interest in hospital treatment cost containment was exemplified by the passage of the Social Security Amendments of 1983 (Public Law 98-21), which mandates the establishment by the Health Care Financing Administration of a prospective payment system for Medicare. This system stipulates that providers be paid at preset rates based on 470 diagnosis-related group categories used to classify the illness of each Medicare-insured person. Rates for each diagnosis were established according to regional and national amounts based on each hospital's urban and rural cost experience. The number of hospitals in the United States in 2012 was reported to be 5723, with more than 920,000 beds. In 2012 the average occupancy rate in hospitals was 65.2%. Large hospitals with 500 beds or more reported higher rates of

occupancy, at 72.6%, whereas the smallest hospitals, those with 6 to 24 beds, had an occupancy rate of 30.8% (USDHHS, 2015b).

Another piece of legislation that targeted cost containment was the Balanced Budget Act of 1997, which also affected Medicare. This act reduced Medicare spending by limiting provider payments, increased options in the choice of managed care plans, and made medical savings accounts an option. As of 2007, medical savings accounts were linked to high-deductible Medicare Advantage plans (Medicare private health plans) and are currently available in some states. Medicare makes an annual deposit into an interest-bearing account on behalf of enrollees, who use the funds to pay for qualified health care expenses until they meet the deductible, at which point the plan will pay for all Medicare-covered services.

The Medicare Modernization Act of 2003 promotes private managed care plans to reduce the burden on the economy of Medicare entitlements. These HMO plans, called Medicare Advantage plans, discussed previously, typically have clients who are healthier than the average Medicare client. Older adults who are enrolled in these plans pay a monthly premium and are required to choose providers within the network. If care is provided outside the network of providers, individuals must usually pay out-of-pocket costs similar to those of other HMOs discussed earlier. This can be confusing to the older person because there are many Medicare Advantage plans to choose from and the person may not realize how a Medicare Advantage plan is different from traditional Medicare coverage. Provisions have been made for enrollees to change Medicare Advantage plans or to be disenrolled during specific time frames. Providers have been lobbying for increased reimbursement because Medicare dictates reimbursement fees based on a predetermined formula.

Care management.

Care management began through public programs with nurses in public health departments, social workers in public welfare systems, and caseworkers in mental health departments. In care management, an experienced health care professional, such as a nurse, social

worker, or gerontologist, helps determine the nursing care that is necessary, monitors that care, and arranges for individuals to receive care in the most cost-effective and most appropriate setting. Care managers are especially effective in meeting the needs of individuals recently discharged from the hospital, older adults, persons with medical conditions that are costly to treat (e.g., spinal cord injuries or persons with high-volume diseases such as chronic illnesses), persons with complex health and social needs, and other cases requiring multiple levels of care. The care manager must achieve a balance between cost and quality and must collaborate effectively with all providers involved, both inside and outside the health plan, and with the person's family to ensure appropriate quality care. Emphasis must be on health management across the continuum of health care services. As Medicaid and Medicare managed care systems continue to develop, demand for nurses to fill the care management role will continue to grow. In addition to working within organizations, care managers can have their own independent practices. Managed care organizations rely on care management to reduce inappropriate use of services, improve quality of care, and control costs (Nies & McEwen, 2014). Basic care management services are described in Box 3-11.

Box 3-11

Care Management Services

- *Assessment:* Evaluating a person's physical, social, functional, psychological, financial, and spiritual needs, including the family within a specific environment
- *Care planning:* Setting goals and identifying specific services to meet individual and family needs, including how to allocate resources and refer to other resources
- *Geriatric care manager:* Manager who develops an individualized care plan for older adults with medical, functional, and cognitive conditions to receive care and services to remain at home, avoiding

costly hospitalizations and emergency department visits when possible

- *Service coordination and referral:* Facilitating and coordinating access to needed providers
- *Care monitoring and periodic reassessments:* Evaluating progress, access to and use of services, and changes in needs

Managed Care Issues

Managed care options will once again become more plentiful as states devise health care delivery systems to meet the ACA mandates. With a need to not only control costs but also to improve the functioning of the health care system to provide high-quality evidence-based care, new systems with groups of providers delivering care in more efficient ways must evolve. The use of technology has become a valuable resource for informing consumers and employers about health care issues and allowing them to search for and compare information on various types of health care plans. The Internet is also a tool nurses can use for their own continuing education needs, as well as to enhance others' education within a facility, public library, or home. Nurses can steer individuals toward appropriate websites for health-promotion and disease-oriented information (see the case study at end of this chapter). With the rapid expansion of scientific advances in health and medicine, it is not possible for the nurse to stay abreast of the growing body of research evidence without Internet assistance. Evidence-based practice is key in the provision of safe, quality nursing care. Registered nurses and APNs need to be able to obtain the best evidence, appraise the findings, and then apply them to practice with consideration of the culture and beliefs of the individual (Melnyk & Fineout-Overholt, 2014).

Health Insurance

Positive elements of the health care system in the United States

include excellent clinicians, health care facilities, and equipment—all of which are readily available to people with health insurance and adequate finances. The US system exhibits a high degree of technological change and innovation and excellent information, quality, and cost-accounting systems. Numerous studies have found that those who do not have health insurance are at risk of poorer health outcomes. The ACA has significantly decreased the number of those uninsured in states that have expanded their Medicaid programs and because most Americans are now required by federal law to purchase or obtain health insurance. A high number of uninsured individuals are disproportionately low-income persons and measures as discussed previously will increase the number of individuals in both private and public health plans. The plan does not address noncitizen foreign-born persons who have entered and are living in the United States illegally.

Private Health Insurance

In the private sector, the following five types of organizations provide health care insurance:

- Traditional insurance companies (including the earliest insurer, Blue Cross, and Blue Shield, a nonprofit charitable organization) and for-profit commercial insurance companies
- PPOs acting as "brokers" between insurers and health care providers
- HMOs, which are independent prepayment plans
- POS plans, which combine features of classic HMOs with person choice characteristics of PPOs
- Self-insurance and self-funded plans, in which either the employer takes on the role of insurer or the enrollee sets up a trust account with tax savings.

Traditionally, private insurers charged employers or individuals annual premiums and provided services on a fee-for-service basis. Organized at the state and local levels, Blue Cross and Blue Shield

generally complement each other, with Blue Cross reimbursing hospitals and Blue Shield covering physicians and other providers. After World War II, insurance companies began to provide health insurance plans in competition with Blue Cross and Blue Shield. Today, more than 800 commercial, profit-making insurance companies, such as Metropolitan Life and Aetna, offer policies that cover hospitalization and in-hospital or office-based physician care, and other major medical expenses. Much of the individual insurance sold today is supplementary, such as that designed to supplement Medicare, known as Medigap. These plans reimburse only deductibles and co-insurance payments associated with Medicare.

HMOs attempt to lower health care costs by emphasizing preventive rather than curative care, decreasing the progression and severity of some illnesses. Care is provided in outpatient settings when possible, and HMOs tend to use fewer services, with emphasis on the least costly means of providing a service.

POS plans enable enrollees to choose, at the POS, whether to use the plan's provider network or seek care from non-network providers. Typically, network providers are paid on a capitated or discounted fee basis, and non-network providers are paid on a fee-for-service basis.

Another change in the structure of the insurance industry is the growth of self-insured or self-funded plans. Self-insurance means that an employer (or union) assumes the claims risk of its insured employees, whereas self-funding refers to paying insurance claims from an established fund, such as a bank account or trust fund.

Public Health Insurance and Assistance

Medicare.

Medicare is a federal health insurance program that finances medical care for people older than 65 years, disabled individuals who are entitled to Social Security benefits, and people with end-stage renal disease requiring dialysis or a kidney transplant. The Medicare program, also known as Title XVIII of the Social Security Amendments, began in 1966 after decades of debate and is currently

operated under the administrative oversight of the CMS. Medicare is an entitlement program, meaning individuals who contributed to Medicare through taxes are "entitled" to the benefits regardless of the amount of income and assets they have. The intent of Medicare was to protect older adults against the catastrophic financial debts often incurred in managing chronic illness and to assist in the payment of health care. In 1983 Medicare added hospice benefits for the last 6 months of life to cover services for the terminally ill. Hospice is based on a philosophy that views death as a normal part of the life cycle and emphasizes living the remainder of life as fully and comfortably as possible. Hospice care accounts for only a small amount of total Medicare expenditures. The total Medicare benefit payments in 2014 equaled $597 billion, accounting for 14% of the federal budget and 22% of the total national health spending in 2013. Twenty-six percent of Medicare expenditures went to Medicare Advantage plans, 23% went to hospital in patient services, 12% went to physician payments, 14% went to other payments (such as hospice, durable medical equipment, and Part B drugs), 11% went to outpatient prescription drugs, 3% went to home health, and 5% went to skilled nursing. There are four parts in the Medicare plan: Medicare Part A (hospital insurance), Medicare Part B (medical insurance), Medicare Part C (Medicare Advantage), and Medicare Part D (Medicare prescription drug coverage) (KFF, 2015c).

Medicare Part A is financed largely through a mandatory tax of 2.9% of earnings paid by employees and their employers (1.45% each) into the Hospital Insurance Trust Fund, which accounts for 87% of Part A's revenue. Individuals who earn more than $200,000 and $250,000 or more as a couple pay a higher payroll tax on earnings of 2.35%. Part A covers inpatient care in hospitals, skilled nursing facilities (not custodial or long-term care), home health services, and hospice care. For those individuals who have contributed to Medicare or whose spouse has contributed to Medicare for 10 years in Medicare-covered employment, there is no monthly premium for Part A. For those individuals who have not contributed for 10 years, premiums are pro-rated to the number of months (quarters of

Medicare-covered employment), and in 2016 were up to $411 per month. The Part A benefits are subject to a deductible ($1288 deductible for each benefit period in 2016) and copayments, which differ depending on the number of days for each benefit period. For example, for days 1 to 60 there is zero co-insurance, for days 61 to 90 there is $322 co-insurance per day of each benefit period, and there are increased co-insurance rates for day 91 and beyond with defined limits (Medicare.gov, n.d.). Even if an individual does not pay a monthly premium for Part A, inpatient deductibles and co-insurance charges may be difficult for many older adults to manage as a result of fixed incomes.

Part B is supplementary voluntary medical insurance financed through a combination of general tax revenues (73%) and 25% of premiums paid by beneficiaries ($109.00 per month in 2016 with a $166 annual deductible). The Medicaid program pays the premium for low-income Medicaid beneficiaries. People with incomes $85,000 or higher or $170,000 for couples pay a higher income-related monthly Part B premium ranging from $152.78 to $349.13 per month in 2016. The ACA freezes the income thresholds for Part B through 2019. Beginning in 2020, income thresholds will be indexed to inflation and premiums are expected to grow. Part B covers physician visits, outpatient services, preventive services, and home health visits. Once the deductible has been met, individuals typically pay 20% of the Medicare-approved amount for most physician services, in-hospital physician services, outpatient therapy, and durable medical equipment (Medicare.gov, n.d.).

Part C refers to the Medicare Advantage program as previously discussed. Medicare Advantage programs such as HMOs and PPOs cover all of Part A and Part B, and typically Part D.

Part D is the voluntary, subsidized outpatient prescription drug benefit with additional subsidies available for low-income beneficiaries. Part D is financed through general revenues (74%), beneficiary premiums (15%), and state payments for dually eligible people (11%). The Part D benefit is offered through private plans that contract with Medicare. There are Medicare Advantage prescription

plans and stand-alone prescription plans. The ACA includes a number of provisions that have enhanced benefits and gradually eliminated the Part D prescription drug coverage gap known as the donut hole. The Part D monthly premium differs by plan (KFF, 2014).

Individuals enrolled in both Medicare and Medicaid programs (duel) are considered vulnerable populations (older adults and poor), and Medicare premiums are subsidized. Medicare benefit payments accounted for 14% of the total federal spending in 2013 (Figure 3-11). The financial status of Medicare can be measured by the level of assets in the trust fund, compared with the level of benefit spending. If spending exceeds assets, the fund will become fully depleted. Each year the trustees predict the solvency of the trust fund (year in which funds will be fully depleted). In 2015, the trustees predicted the solvency of the Medicare Hospital Insurance Fund will be depleted in 2030 as the baby boom generation will reach Medicare eligibility and there will be a declining number of workers per beneficiary, resulting in a decrease in payroll tax contributions to the fund. The projected year to insolvency has varied, and the full impact of the ACA has not been fully realized. Future challenges include increased costs of health care services, increased costs of technology, and increased volume and use of services attributable to population growth of older adults and increasing life expectancy. The number of older adults (65 years or older) and nonelderly disabled (younger than 65 years) who are enrolled in Medicare has increased steadily since 1966 (Figure 3-12), with 52 million in 2013. Neither Part A nor Part B of Medicare offers comprehensive coverage. Inherent in the program are deductibles, set amounts that the individual must pay for each type of service before Medicare begins to pay, and copayments, a percentage of charges paid by the individual. There are also limitations on the amount of coverage provided.

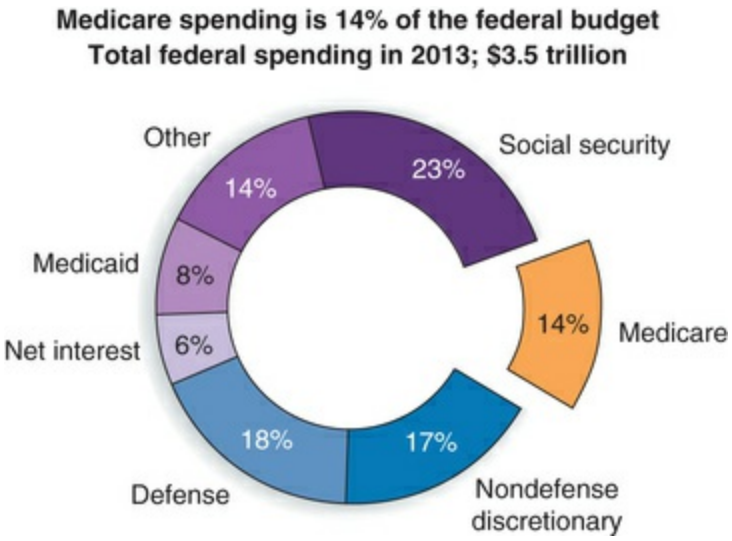

FIGURE 3-11 Medicare spending is 14% of the total federal spending, fiscal year 2013. All amounts are for fiscal year 2013. (From Congressional Budget Office, updated budget projections: 2014 to 2024, April 2014. Slide available from the Kaiser Family Foundation. http://kff.org/Kaiser-slides/.)

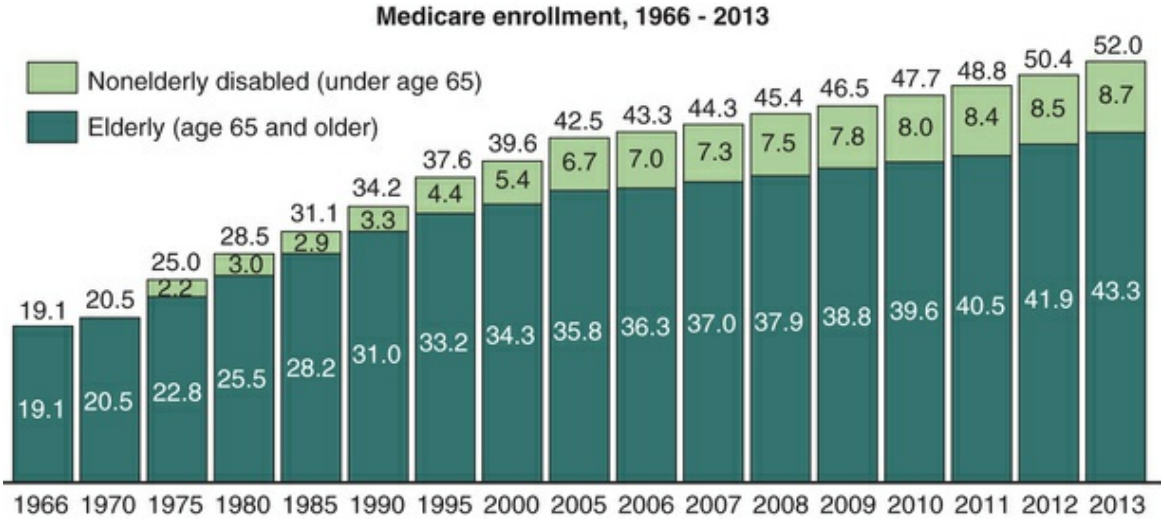

FIGURE 3-12 Medicare enrollment, 1966 to 2013. The numbers may not sum to the total because of rounding. People with disabilities younger than 65 years were not eligible for Medicare before 1972. (From Kaiser Family Foundation. Sources Centers for Medicare & Medicaid Services. Medicare enrollment: Hospital insurance and/or supplemental medical insurance programs for total, fee-for-service and managed care enrollees as of July 1, 2011: Selected

calendar years 1966-2011; 2012-2013, HHS budget in brief, FY 2014. https://kaiserfamilyfoundation.files.wordpress.com/2013/06/july-2013-medicare-kaiser-slides.pptx.)

Out-of-pocket expenses do not include premium payments for Part B or for supplemental private health insurance, which can add significantly to out-of-pocket expenses. A comprehensive booklet available on-line or through the CMS details information on enrollment, costs, and services that are covered and not covered. With some exceptions, services not covered include acupuncture, chiropractic services (unless medically necessary to correct subluxation), and custodial care (activities of daily living such as help bathing, dressing, eating, getting in and out of bed). Other services that are not covered include most dental care such as cleanings, fillings, extractions, dentures, routine eye care, and spectacles for nondiabetic individuals, routine foot care for nondiabetic individuals (cutting or removal of corns, calluses, cutting of nails), hearing aids, long-term care (if only custodial care is needed), and health care while traveling outside the United States. Items not covered, especially custodial care, contribute significantly to out-of-pocket expenses. The main population at risk, the older adult, may have limited financial resources to seek preventive health services not covered. Some low-income enrollees may qualify for Medicaid services if income requirements are met, and others may have additional benefits through private insurance (Medicare.gov, n.d.).

In the Omnibus Budget Reconciliation Act of 1989, Medicare revised its payment scheme for physicians, assigning relative values to services on the basis of the time, skill, and intensity required to provide them, and a second limit was set on the amount that physicians could charge individuals above the amount that Medicare pays. This restriction was designed to limit growth of Medicare costs for physician payments.

The Balanced Budget Act of 1997, the Balanced Budget Refinement Act of 1999, and the Benefits Improvement and Protection Act of 2000 added services to the Medicare benefits package. These services include coverage for some screening tests, diabetes monitoring and

diabetes self-management, and some immunizations.

The missing Medicare benefit causing great concern was the rising cost and lack of coverage for outpatient prescription drugs. On December 9, 2003, President George W. Bush signed into law the Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (Public Law 108-173). This lengthy piece of legislation amended Title XVIII of the Social Security Amendments to provide a voluntary program for prescription drug coverage and to modernize the Medicare program. The Medicare prescription drug benefit Part D started on January 1, 2006, and covers some of the costs for prescription drugs. Different plans cover different drugs and require older adults to choose a plan that best meets their needs from a plethora of choices. Those with low education or literacy levels, as well as debilitated older adults in long-term care facilities, may have difficulty selecting the best plan for their individual needs. The average monthly premium cost in 2016 is projected to be about $39.00 but may be higher in some plans and for those with higher incomes. The original Part D plan required the first $250 of prescription drug costs to be paid by the older adult each year. Medicare then pays 75% of the next $2000 worth of drugs on the plan's formulary. After that, there is a gap in coverage known as the "donut hole," where individuals pay 100% of drug costs until another $2850 has been spent out-of-pocket. At that point, Medicare will begin paying about 95% of the cost of covered drugs until the end of the calendar year. The ACA will gradually close the donut hole gap in prescription coverage (see http://www.cms.gov for the most up-to-date costs).

Medicaid

Medicaid is an essential health insurance program available to certain low-income individuals and families who fit into an eligibility group that is recognized by federal and state law (Figure 3-13). Medicaid pays health care providers directly if they participate in the Medicaid program.

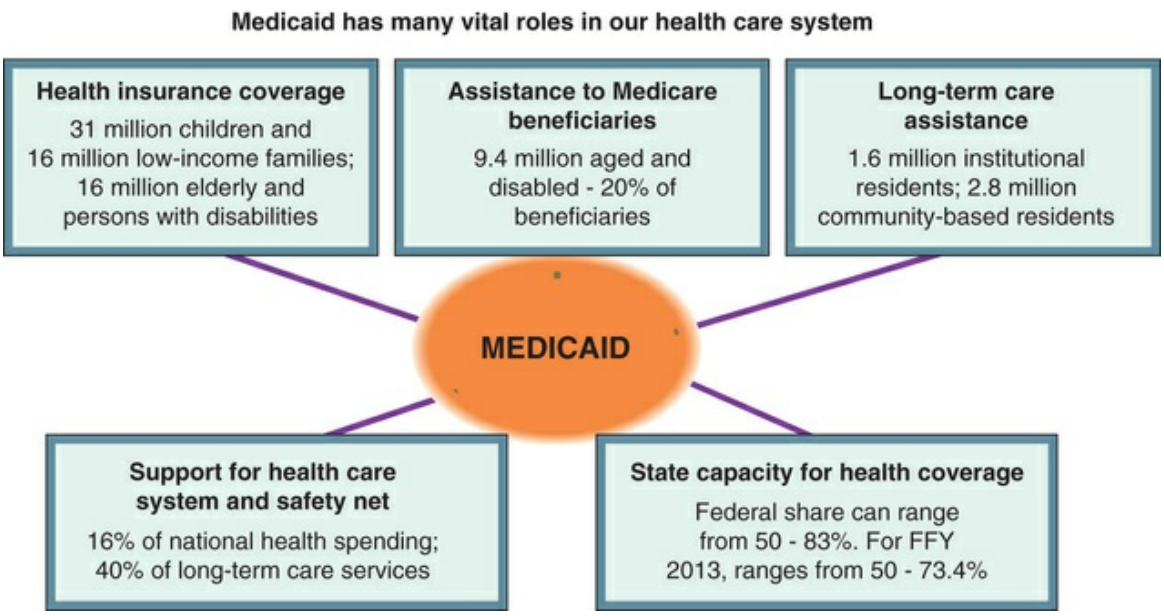

FIGURE 3-13 Medicaid has many vital roles in our health care system. *FFY*, Federal fiscal year. (From Kaiser Commission on Medicaid and the Uninsured. http://kaiserfamilyfoundation.files.wordpress.com/2013/03/medicaid-has-many-vital-roles-in-our-health-care-system-medicaid.png.)

Medicaid is an assistance program, commonly referred to as welfare, managed jointly by the federal and state governments to provide partial or full payment of medical costs for individuals and families of any age who are too poor to pay for the care. Medicaid legislation, Title XIX of the Social Security Amendments, came into effect in 1967. The federal government provides funds to states on a cost-sharing basis, with 50% to almost 80% from the federal government and the remainder from the state, according to the per capita income of each state, to guarantee medical services to eligible Medicaid recipients.

Medicaid is an integral part of the health care system, providing health insurance coverage for 37% of all children, 51% of nonelderly people below the federal poverty level, and 64% of nursing home residents (Figure 3-14). Medicaid serves as a safety net for low-income and high-need Americans.. Poverty guidelines are issued by the USDHHS to be used to determine financial eligibility for some federal programs. In 2015, the federal poverty level was $11,770 for individuals and $15,930 and for a family of two (USDHHS, n.d.b). The

program will also support individuals and families with subsidies for insurance coverage in state-based health benefit exchanges. Individuals and families with income levels of 133% to 400% of poverty levels will be eligible to receive subsidies to assist in paying for health premiums. Previously, states established income eligibility requirements for their Medicaid program, and 47 states had income-eligibility levels for children in the Medicaid/CHIP program of 200%. Before the ACA, states could not cover nondisabled adults without children in a Medicaid program. As mentioned previously, the Supreme Court supported states' rights not to expand Medicaid eligibility. States that have not expanded Medicaid programs have higher numbers of uninsured people.

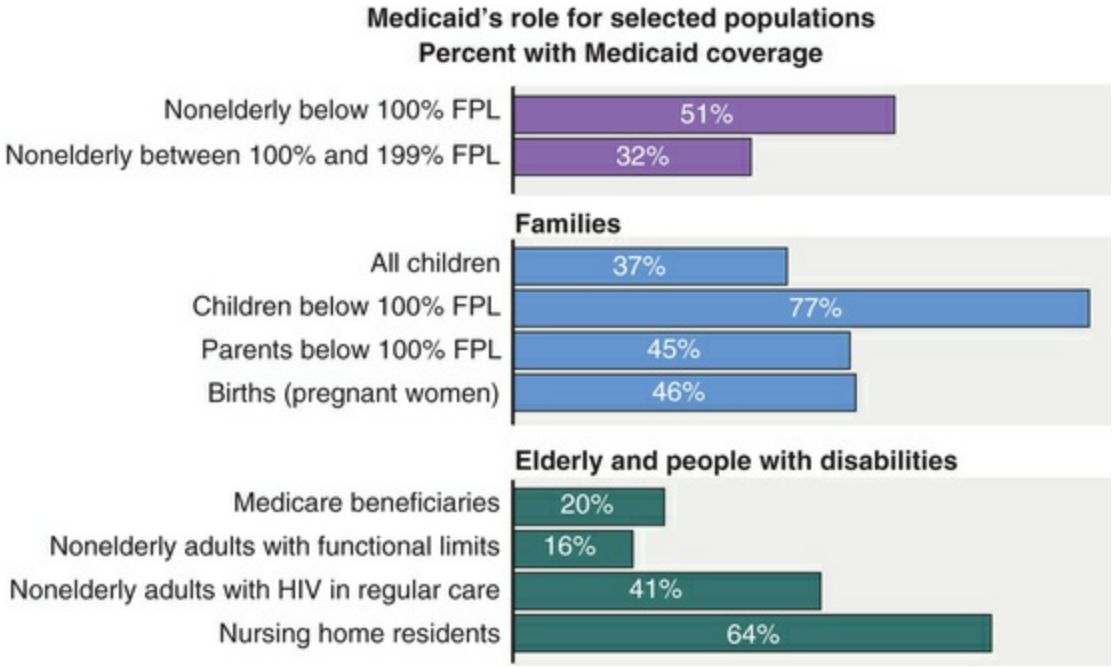

FIGURE 3-14 Medicaid's role for selected populations. The federal poverty level (FPL) was $19,530 for a family of three in 2013. (From Kaiser Commission on Medicaid and the Uninsured [KCMU] and Urban Institute analysis of 2013 CPS/ASEC supplement; birth data-maternal and child health update, National Governors Association, 2012; Medicare data-Medicare Payment Advisory Commission, data book: Beneficiaries dually eligible for Medicare and Medicaid (January 2015), 2010 data; functional limitations-KCMU Analysis of 2012 NHIS data; nonelderly with HIV-2009 CDC MMP; nursing home residents-2012 OSCAR data. Slide available from the Kaiser

Family Foundation. http://kff.org/Kaiser-slides/.)

Additionally, Medicaid pays the Medicare premiums, deductibles, and co-insurance for certain low-income Medicare recipients. Medicaid plans are open-ended, meaning a state must admit into the program at any time all individuals who meet the criteria. A state is not allowed to cap the Medicaid budget for a particular fiscal year, thus making it difficult to determine exactly how much money needs to be appropriated.

States administer Medicaid under federal requirements and guidelines. The ACA mandates minimal essential health benefits, typically those that are offered in an employer's health plan must be offered, but states can provide enhanced benefits and offer a more comprehensive plan. Programs differed widely among states in terms of services covered. In summary, the ACA of 2010 includes a significant expansion of the Medicaid program, covering more of the uninsured and providing subsidies to help low-income individuals buy coverage through newly established health benefit exchanges.

The federal government, in the passage of the Deficit Reduction Act of 2005, made it harder for individuals to qualify for Medicaid nursing home benefits by increasing penalties on individuals who transferred assets for less than fair market value during the previous 5 years. Since long-term care is expensive, purchasing private long-term care insurance to cover nursing home care became an option in some states. Individuals who already have long-term care needs are not eligible, and the cost of the premium increases with an individual's age. For older persons, the cost of the premium makes long-term care insurance unaffordable.

Passage of the welfare reform bill in 1996 (Personal Responsibility and Work Opportunity Reconciliation Act of 1996, Public Law 104-193) revealed a significant philosophical shift in federal thinking about welfare assistance in the United States. For the first time, Medicaid was not linked directly to welfare programs. Ending a 61-year guarantee of federal aid, the Temporary Assistance for Needy Families program (formerly Aid to Families with Dependent Children) established by this legislation provides temporary financial

aid with a 5-year lifetime limit. Legal immigrants who arrive in the United States after the passage of this bill must wait 5 years to become eligible for programs. The aim was to help parents become self-sufficient through welfare-to-work programs.

As part of the Balanced Budget Act of 1997, CHIP was enacted to provide health insurance coverage to children whose family's income is below 200% of the federal poverty level or whose family has an income 50% higher than the state's Medicaid eligibility threshold (CMS, n.d.). Some states had expanded their CHIP eligibility to include family coverage (see the previous discussion). The ACA has expanded Medicaid eligibility (see the previous discussion).

Pharmaceutical Costs

The spiraling cost of prescription drugs continues to add to the complexity of providing adequate health care. Newer drugs cost more than the drugs they replace and contribute 50% of the increased cost. Increased use of prescription drugs adds to an increased cost per day of medications. Consumer demand sparked by drug advertisements, new indications for use, and increased consumer knowledge of available drugs has increased the demand for prescription medications. Increased drug cost is attributed to inflation, more days of therapy per user, greater number of drugs per user, cost of research and drug development (Box 3-12), and advertising costs. As discussed earlier, Part D of Medicare is the prescription drug component of the Medicare plan.

Box 3-12

Genomics

Genetics and Pharmacogenetics

The field of pharmacogenomics is rapidly expanding what is known about the influence of hereditary genetic attributes and how drugs respond in the body. A number of drugs have been found that affect

certain ethnic groups and individuals in different ways. Individuals who metabolize a specific drug slowly (slow acetylators) will take longer to metabolize the drug into the active form and retain the active drug longer in the body. Slow or poor metabolizers may require a lower dose or a different choice of drug to avoid toxicity. Rapid metabolizers (fast acetylators) metabolize drugs quickly into the active form, which may then be metabolized more quickly into the inactive form, leading to therapeutic drug failure. Fast metabolizers may require no dosage adjustment or higher dosages for the dosage to be therapeutic. Other genetic variations in drug-metabolizing enzymes exist that significantly impact how a drug is metabolized. As the field of pharmacogenetics evolves, tools that determine genotyping of an individual may be used routinely to guide practitioners in the selection of therapeutic options. Optimal medication dosage and selection of drugs may personalize drug treatment regimens, preventing adverse effects and contributing to better patient outcomes. The financial and ethical decision-making aspects of the use of genotyping technology in medical decision-making will be issues to address in future health care legislation.

The Uninsured: Who are They?

The number of uninsured Americans younger than 65 years was estimated to be 46 million in 2008 and rose as a result of the economic downturn and the growing cost of health plan premiums (KFF, 2012). The 2010 ACA is expected to reduce the number of uninsured significantly with the expansion of Medicaid, subsidies to pay premiums in health insurance exchanges, a federal mandate requiring most legal citizens to enroll in an insurance plan or face tax penalties for noncompliance, and a provision allowing children to remain on their parents' employer family insurance until the age of 26 years (Figure 3-15). Previously, when children reached the age of 19 years and were not full-time college students, they were deleted from employer family insurance plans. Even with all the new options

afforded by the ACA, a number of individuals will remain uninsured. Undocumented immigrants (those who are noncitizens and are living in the United States illegally) do not qualify for Medicaid or any other public insurance plan and are also exempt from paying the federal tax penalty. This population is extremely vulnerable because of language and cultural barriers and fear of being discovered as an illegal immigrant; therefore they typically do not seek health care. Provisions in current law require emergency care to be provided as well as care to be provided to pregnant women, regardless of alien status (KFF, 2010a). Another group of individuals are those who choose not to enroll in a qualified insurance plan and instead elect to pay the annual federal tax penalty. The ACA includes a federal tax penalty for individuals who do not obtain coverage beginning in 2014. The penalty increased every year for the next 3 years for any individual not exempted from the requirement who does not have coverage. For example, the per-adult penalty in 2014 was $95, rose to $325 in 2015, and rose to $695 in 2016. Exemptions from the federal penalty include undocumented immigrants, those whose incomes are below the minimum amount required to file federal income tax returns, those with incomes below 138% of the poverty level in states that have not expanded eligibility for Medicaid, and those who would have to pay more than 8.13% of household income for insurance. In 2016 the tax penalty was calculated to be the greater of the following two amounts: a flat dollar amount of $695 per adult and $347.50 per child, up to a maximum of $2085 for the family, or 2.5% of family income in excess of the 2015 income tax filing thresholds ($10,300 for a single person and $26,600 for a family). It is estimated that 7 million uninsured people are eligible for marketplace premium subsidies to assist with the cost of premiums. For about half who qualify, the cost of the lowest plan (a bronze plan) would have a zero premium cost. For others (an additional 3.5 million people) the cost of a bronze plan using their premium subsidy would be less than the penalty. However, although the cost of the premium for a bronze plan may be zero or reduced, which fulfills the ACA mandate, bronze plans typically have a higher copayment when used. The next level of

insurance premiums, called silver premiums, may have a higher premium cost but significantly less copayment cost at the time of use. Health care providers and nurses need to stay abreast of all of these changes to help individuals and families navigate the complexities of the financial aspects of insurance. Once this portion of the law is fully enacted, it is expected that many more Americans will choose to obtain coverage as it will be less costly than paying the penalty. For some, the reality of the ACA insurance mandate will not be realized until federal tax returns are filed for 2016, in the early part of 2017 (KFF, 2016). Nurses and health care providers can assist individuals and families in both gaining coverage and selecting a plan that best suites their needs. Another group of individuals who may not have coverage are noncitizens who are legally traveling within the United States (business, education, tourism) unless they have purchased secondary travel insurance before entering the United States.

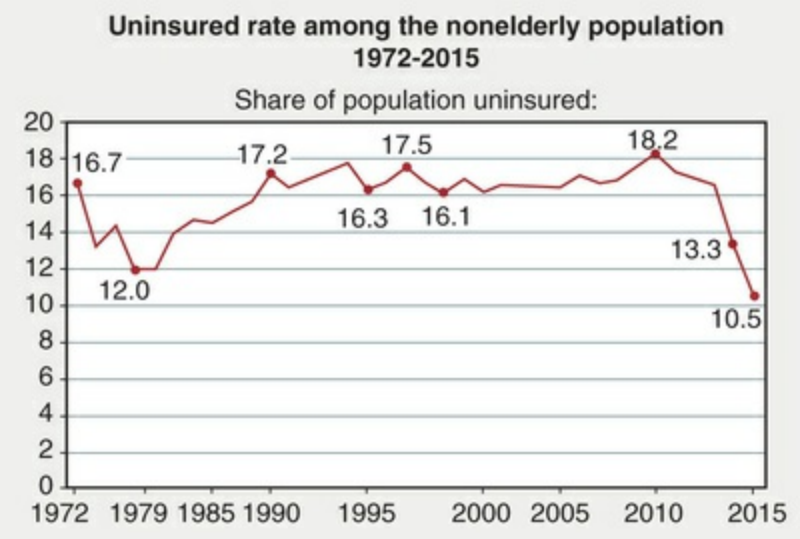

FIGURE 3-15 Uninsured rate among the nonelderly population 1972 to 2015. The 2015 data are for the first and second quarters only. (From Centers for Disease Control and Prevention/National Center for Health Statistics, National Health Interview Survey, reported in http://www.cdc.gov/nchs/health_policy/trends_hc_1968_2011.htm#table01 and http://www.cdc.gov/nchs/data/nhis/earlyrelease/insur201511.pdf. Slide available from the Kaiser Family Foundation. http://kff.org/Kaiser-slides/.)

Unauthorized Immigrants

The Pew Research Center (Gonzalez-Barrera & Krogstad, 2015) and the US Department of Homeland Security (2014) estimated the number of illegal aliens in 2014 in the United States was 11.3 million, or 3.5% of the nation's population. Almost 50% of unauthorized immigrants are from Mexico. Although it is difficult to determine exact numbers, in 2012, 8.1 million unauthorized immigrants were estimated to be working or looking for work. Some unauthorized immigrants entered the United States without valid documentation, whereas others arrived with valid visas but stayed past the visa expiration date. About 60% of unauthorized immigrants are located in six states: California, Texas, Florida, New York, Illinois, and New Jersey. Immigration reform remains a contested project with concern about both entry into the country and how to deal with unauthorized immigrants who are already living in the United States. In 2013, 662,483 individuals were apprehended: 438,421 individuals were removed and 178,371 individuals were returned. This is the lowest number of returned or removed individuals since 1972 (Gonzalez-Barrera & Krogstad, 2015). According to federal law, anyone entering an emergency department must be treated regardless of the ability to pay or immigration status. However, those individuals who are in the United States illegally may be reluctant to seek health care for fear of legal action, being removed, or being returned. This vulnerable population is not eligible to enroll in Medicare or Medicaid programs and have various unmet health care needs.

Health Care Systems of Other Countries

The United States spends the highest proportion of its GDP on health care of all industrialized countries (see Figure 3-4) with a reported GDP of 16% in 2008, 5.9% above the global average for the countries listed. The United States has the highest cost per capita (see Figure 3-2), reporting $7538 dollars were spent per person in 2008 compared with the next highest amount (Norway) at a little over $5000 and the lowest amount reported (Japan) at $2700. Figure 3-3 shows a graphical representation of the growth in health care expenditure per capita for different countries over time. The countries represented in Figures 3-2 and 3-3 all have some version of a universal health care plan and spend less money per capita. Life expectancy rates are higher and infant mortality rates are lower in these countries than in the United States. Although each country has a different type of health plan, all share many of the same problems of the US free-market system. As mentioned earlier, rising health care costs; issues of access and affordability; workforce shortages of health care providers; increased concern over medical errors, quality of care, and safety; changing demographic population trends; and escalating health care costs are some of the inherent issues faced by all nations in providing health care.

Canadian Health Care System

The Canadian health care program, called Medicare, is a group of socialized health insurance plans that provide health coverage to all Canadian citizens regardless of medical history, personal income, or job status. The Canada Health Act, legislated at the federal level, determines what services must be provided, similarly to the Medicaid program in the United States, but provinces and territories may provide additional services not listed in the Canada Health Act. The Canada Health Act specifies basic services, including primary care

and hospitalizations, leaving the individual province or territory responsible for the management, organization, and delivery of health services for its residents. The Canada Health Act does not include services such as physical therapy, dental coverage, corrective lenses, home care, or prescription medicines, but separate provinces can elect to provide enhancements. Some employers also offer private insurance plans to supplement the Canadian health care plan for services not offered, such as corrective lenses, medications, and home care. Every Canadian citizen has the same basic primary health insurance that is covered by the national health care plan. Each Canadian citizen applies for a provincial health card and, once it has been issued, the card provides access to a person's medical information and is used when the citizen visits a physician or health care provider, eliminating the need to fill out forms. Canadians pay for health care through a variety of federal and provincial taxes, just as US residents pay for Social Security and Medicare through payroll taxes. The federal government appropriates funds to the provinces and territories through cash and tax transfers. Because the government is the primary payer of medical bills, Canada's health care system is referred to as a single-payer arrangement. Some provinces gain additional funds through sales tax, lottery proceeds, and health premiums. Additional benefits differ among the provinces, but most provide prescription drugs to older adults and low-income clients. For Canadians with higher incomes and private supplemental insurance, private clinics are available that offer specialized services. The advantage of receiving care in a private clinic is reduced wait times for services. Private clinics offer specialized services not covered by the public health plan. Canadians covered by private health insurance typically have 80% of the costs covered at private clinics. Higher-income Canadians can pay out-of-pocket for care received at private clinics, which typically offer services with reduced wait times. For example, obtaining a magnetic resonance imaging scan in a hospital may require a waiting period of months, whereas a private clinic could offer the scan much earlier. Canadians with private health insurance and higher incomes have access to greater health care

services and more expedient health care (Health Canada, 2016).

At one time, the Canadian system seemed to be an ideal model that the United States should adopt; however, increasing health care costs, access issues, delays in treatment, and workforce shortages of health care providers have caused political controversy and debate in Canada. Queuing refers to a system where a person is placed on a wait list before receiving certain types of tests or surgery, allowing a person who is in need of more immediate care to receive priority. If care needs are determined not to be life threatening, persons may need to wait for magnetic resonance imaging scans, heart bypass surgery, cataract removal, or hip replacement procedures for months because persons in urgent need of the procedures are higher on the list. Although all citizens receive the same level of public health care, private insurance allows a two-tiered system favoring Canadians with private health insurance or other financial resources to receive expedited care. If a person can pay out-of-pocket, he or she may elect to travel elsewhere (e.g., to the United States) to receive expedited care. A major shortage of physicians and nurses in Canada is due in part to lower reimbursement rates by the public health system as well as lower salaries, causing some health care providers to leave Canada and practice in other countries such as the United States. Over the years, the federal government has decreased contributions to the provinces and territories because of large federal budget deficits and limited fee increases to physicians for services. Regionalization of hospitals has caused access to care issues for those outside major cities. Expansion to offer better access to home care and community-based services is an emerging issue (Health Canada, 2016).

Case Study

Health Teaching: Using the Internet to Increase Health Literacy

Ella, age 34 years, has been married for 10 years to her husband Joe and recently moved to a new area with their two children, Billy, age

11 years, and Olivia, age 6 years. Joe just started a new position in a state agency and Ella plans to work 3 to 4 days a week as a home health aide. Joe completed a 2-year college degree, and Ella took a few college courses but never finished her degree. The family is new to a primary care clinic, and Ella asks the nurse for advice in choosing a health plan that will best meet the needs of her family. Ella and her husband would like to have a third child in the next year or so. Her husband Joe was given a folder at his new job with multiple health plans to choose from and asked Ella to "just pick one" because they are too complicated to understand. Joe considers himself healthy and active, although he has had recommendations in the past to lose 14 kilograms (30 lbs), is borderline hypertensive, and has slightly elevated blood lipid levels. He has a strong family history of coronary artery disease, and his father died of a myocardial infarction at the age of 65 years. Ella also struggles with her weight and often relies on fast food for quick dinners on the days she works. Their son Billy has attention-deficit–hyperactivity disorder and Olivia has asthma. Both children are above the recommended body mass index for their ages. The family has a home computer with Internet access, and Ella states she is "getting better at using it as her sixth grade son is learning computer literacy in school and is teaching Mom."

The nurse discusses the family's general health-promotion and health-protection needs and the special needs presented by the diseases that have been identified. She provides some resources for Ella to learn more about the health plans available to her and consumer-friendly health information websites.

Reflective Questions

- What additional information does the nurse need to assess this family's needs?
- What are the priority area teaching needs for this family?
- What community resources might be available to Ella and her family?

- What are some appropriate websites that Ella might find useful?

Before leaving, the nurse suggests the following:

- From the Agency for Healthcare Research and Quality, a federal government agency with health information for consumers on guidelines in choosing a health plan: http://www.ahrq.gov/consumer/insuranceqa/.
- From the US Department of Labor, a federal agency that provides information on health plans, benefits, and has many links: http://www.dol.gov/.
- For health care information on multiple topics:
- Health Care Information: http://www.himss.org
- WebMD: http://webmd.com/
- Healthfinder: http://healthfinder.gov/
- Mayo Clinic: http://www.mayoclinic.com/

Summary

The nursing workforce, composed of more than 3 million nurses, is the largest segment of the nation's health care workforce, and nurses will be key players in moving forward the objectives set forth in the 2010 ACA and *Healthy People 2020*. To move these agendas forward, nurses need to understand the complexity of the health care system—the structures (federal, state, and local) and the financing mechanisms (public and private)—so interventions can be targeted to reduce health disparities, promote health equity, and elevate the level of health and wellness across the population. The IOM recognized a number of barriers exist that prevent nurses from being able to respond effectively to rapidly changing health care settings and an evolving health care system. Nurses need to be proactive in shaping policy that affects the health care system and need a working understanding of the complexity of the health care system to be able to educate individuals and families about health care resources, to coordinate services, and to influence health care policy at the local, state, and national levels. To accomplish this task, nurses need to become and remain well-informed citizens and health care consumer advocates.

A historical perspective and a description of the current health care delivery system in the United States provide a framework for the analysis of trends, values, and needs related to health. Awareness of global health indicators sets the stage for the nurse to then compare the health of the nation as a whole. The structure and financing of the health care system, both the public sector and the private sector, are complicated. The influence of recent health reform, the ACA of 2010, sparks an opportunity for nurses to be key players in engaging effectively to deliver high-quality evidence-based nursing care and move forward the agendas of *Healthy People 2020* and the IOM's *Future of Nursing: Leading Change, Advancing Health*.

The Therapeutic Relationship

June Andrews Horowitz

OBJECTIVES

After completing this chapter, the reader will be able to:

- Evaluate values clarification as a prerequisite for effective health promotion.
- Examine the elements and process of communication.
- Analyze differences between functional and dysfunctional communication.
- Develop strategies to promote therapeutic relationships with diverse populations across clinical settings, contexts, and nursing roles.
- Synthesize knowledge of the therapeutic relationship as an essential component of health promotion.

Values clarification

Verbal communication

The therapeutic relationship is the **milieu** (or context, setting) in which nursing care occurs. Nursing practice is shaped by the caregiver's ability to focus on the interests, concerns, and needs of the individual (Peplau, 1991; D'Antonio et al., 2014). Establishing a

therapeutic relationship is critical to problem resolution. The nurse-person relationship comprises the key components of knowing each other, reciprocity, respect, and confidence (Errasti-Ibarrondo et al., 2015). Even in brief interactions, communicating a focus on and concern for the person is critical. A 56-year-old woman who experienced an unexpected myocardial infarction recalls that the clinician who made the most impact on her sat quietly at her bedside for a few moments and made eye contact to discuss what was most important about the woman's rehabilitation plan. What made this brief interaction memorable? It was the clinician's attention to the person who was experiencing the health crisis; it was the quiet pause from the acute care arena activity created by sitting, listening, and making eye contact: it was the clinician's focus on what was most important for the woman's recovery. Across delivery settings, the importance of the nurse-person relationship cannot be forgotten or minimized because of time constraints. As the example shared here illustrates, even episodic brief encounters can have profound effects as shown in this example. Moreover, in today's complex multicultural and global health care arena, nursing's concentration also extends beyond individuals to populations (Fawcett & Ellenbecker, 2015), yet the same critical elements of the relationship remain.

Particularly in health promotion, the nurse-person relationship is the context for care. Health promotion requires sensitivity to each person's goals and values; the individual's and the nurse's. Helping a person adopt health-promoting behaviors requires more than giving information. Health promotion also requires effective communication, which is why communication is a focus area of *Healthy People 2020* (US Department of Health and Human Services, 2010) and thus a priority for nursing practice. Successful health promotion involves interpersonal skills, personal insight, accountability, mutual respect, and a supportive working milieu. Essential to this interactional process are values clarification, communication, and the helping relationship. See Box 4-1: *Healthy People 2020* for the leading health indicators and priorities for action.

Box 4-1

Healthy People 2020

Leading Health Indicators

- Access to health services
- Clinical preventive services
- Environmental quality
- Injury and violence
- Maternal, infant, and child health
- Mental health
- Nutrition, physical activity, and obesity
- Oral health
- Reproductive and sexual health
- Social determinants
- Substance abuse
- Tobacco

Priorities for Action

- Adopt the 12 leading health indicators as personal and professional guides for choices about how to make health improvements.
- Encourage public health professionals and public officials to adopt the leading health indicators as the basis for public health priority setting and decision-making.

- Urge public and community health systems and our community leadership to use the leading health indicators as measures of local success for investments in health improvements.

Values Clarification

Definition

Values are qualities, principles, attitudes, or beliefs about the inherent worth of an object, behavior, or idea that guide action by sanctioning certain actions and disavowing others. Values and beliefs are essential factors in design and implementation of nursing interventions. To serve the unique and diverse needs of individuals, it is imperative that nurses understand the importance of cultural differences by valuing, incorporating, and examining their own health-related values and beliefs and those of their health care organizations, for only then can they support the principle of respect for persons and the ideal of transcultural care (Beard et al., 2015). Cognitive values are those a person ascribes to verbally and intellectually. Active values, in contrast, are those a person physically acts out. Judging the power of a given value by its ability to influence action is important. For example, a nurse may claim to value the worth of all people equally, but may treat individuals of various races differently and provide the most time and concern for those who are racially similar to the nurse. This cognitive value has little power to shape the nurse's behavior. If the nurse treated people of all races with equal respect, the value would also be active and have great power to motivate behavior.

Many forces shape values. Passed down from one generation to another, values color an individual's identity, goals, and sense of personal meaning. Values are embedded in the culture and taught within a family and social context, giving meaning to the life events and happenings outside the family's boundaries (Wright & Leahey, 2013). To engage in health promotion, the nurse must appreciate that values are culture bound and explore how culture, traditions, and practices in a multiethnic and multicultural society influence health-related values. Without this understanding, the nurse is likely to relate to individuals with a limited awareness of their assumptions and inadequate sensitivity to the uniqueness and perspective of the person, family, or community.

Values evolve; they are not static. Life events and social processes can spark a reappraisal of personal values. **Values clarification** is a method for discovering one's values and the importance of these values (Raths et al., 1978). Values clarification does not tell a person how to act, but it helps people recognize what values they hold and evaluate how those values influence their actions.

Box 4-2 outlines seven steps in the valuing process. The first three steps involve a cognitive process, the next two steps involve the affective or emotional domain, and the final steps involve behavior (Raths et al., 1978; Stuart, 2012). The nurse uses values clarification to examine personal values and their potential influence on nursing care, and to help people identify their values and reflect on their connection to health-related behaviors. Box 4-3 lists suggestions for putting values clarification into action. For a values clarification exercise, try following the steps outlined in Box 4-3 in regard to a personal value. Moreover, values clarification requires exploration of both overt and covert factors that affect our perceptions and actions. The process entails taking a virtual flashlight to shine light on our past and current life experiences to examine the values that shape our attitudes and behavior.

Box 4-2

The Valuing Process

Choosing

- Choosing freely
- Choosing from alternatives
- Choosing after careful consideration of potential outcomes of each alternative

Prizing

- Cherishing and being happy with personal beliefs and actions
- Affirming the choice in public, when appropriate

Acting

- Acting out the choice
- Repeatedly acting in some type of pattern

Box 4-3

Techniques for Assisting Individuals to Clarify Values

Identify the Individual's Values

"What is important to you?"

"Which of the following statements sounds most like the way you think?"

"What do you value most in life?"

Use Reflection to Restate the Value and Make It Explicit

"In what you've just told me, I hear that it is very important to you that…"

"I understand that you value…"

Identify Value Conflicts or Conflicts Between Values and Actions

"What connection does this value have to your current health or

illness and to the healthy behaviors, interventions, or treatments needed to maintain or restore your health?"

"How does this particular value affect your behavior and health?"

"What are some ways that you might put your values into action?"

"Are your actions consistent with your values? If not, then what might you change?"

Values clarification becomes a clinical aim when individuals' values lead to behaviors that conflict with the nurse's value of promoting health. For example, a nurse tells a childbirth education class consisting of pregnant women and their coaches that alcohol use poses serious risks to the fetus. After the class, one woman comments, "Do you really think that having a drink once in a while is bad for the baby? I'm sick of being told that I can't do things because of the baby." In this example, an apparent conflict in values between the nurse and the individual exists. Intervention is needed to examine how this woman's wish for freedom from restrictions clashes with her desire to have a healthy child. Nurses must consider their own values related to health promotion for the individual and the fetus and must weigh the importance of respecting individuals' rights to make decisions about their own health behaviors with potential risks to the fetus. Such value conflicts result in ethical dilemmas. Resolution rests on the nurse's ability to examine conflicting values and available evidence about possible outcomes when fashioning health-promotion interventions. Sharing the evidence to support the clinical recommendation also helps to reduce a judgmental message in the communication and opens communication for discussion about the strength of the evidence and its practical implications for health behaviors (Melnyk & Fineout-Overholt, 2011).

Values and Therapeutic Use of Self

Therapeutic use of self is the application of one's cognitions,

perceptions, and behaviors to create interpersonal encounters that promote health in another person, family, group, or community. Without self-awareness and clarification of values, therapeutic use of self is impaired. **Self-concept** and **self-esteem** are interrelated components of individuals' judgments and attitudes about themselves. Self-concept is a mental picture of the self; a composite view of personal characteristics, abilities, limitations, and aspirations. Self-esteem, the affective component of self-perception, refers to how individuals feel about the way that they see themselves. Internalized appraisals from others also influence self-concept and self-esteem.

Self-concept evolves throughout life. From birth, family experiences and parental identification mold the child's sense of identity. Self-esteem is learned from experience. To cultivate children's self-esteem and enable them to have a realistic perception of their strengths and weaknesses, parents should focus on positives, give feedback on abilities and limitations, and provide the child with a sense of belonging and realistic confidence. Positive, rewarding, anxiety-free interactions contribute to security, esteem, and positive self-view. Positive but realistic appraisals from significant others, especially the parents, help the young child to develop this healthy self-view. Parental resources—that is, social determinants of health (such as parental education, household income/zip code)—also have demonstrated positive effects on children's development (Sullivan, 1953; Walker et al., 2011).

The self does not develop solely in response to the reflected appraisals of others. Genetic endowment, experiential opportunities, and the individual's action shape self-concept. People can accept or reject the appraisals of others and modify their behavior. The ability to control actions and evaluate outcomes of interactions allows individuals to modify and alter their views of self. As such, the self is dynamic, changing through interaction with the outside world and in response to the various maturational and situational crises of life.

The ability to examine, reflect on, and evaluate the self is a uniquely human talent. Self-awareness involves interactions between the self and the external world and the symbolic connections created by the

individual. The self includes an unconscious component that is only partially accessible and influences behavior. Self-awareness is influenced by the degree to which an individual has an accurate concept of all dimensions of the self.

The goal of high self-awareness is reached through three steps. The first step is listening to oneself and paying attention to emotions, thoughts, memories, reactions, and impulses. Frequently, people ignore their feelings and thoughts because they are anxious or because they are in a hurry to accomplish some other task. Without self-reflection, people act automatically and lose some of the meaning of living. To improve the ability of self-reflection, ask questions such as the following:

- What am I feeling now?
- What emotions have I experienced today and in the past day or so? What were my thoughts?
- What events led to these thoughts and feelings?
- What actions did I take? Did my behavior fit with my thoughts and feelings, or was there a lack of harmony?
- Was I aware of my reactions at the time that they occurred?
- How have I responded in clinical situations lately?
- How did I react in response to a particularly happy, sad, or difficult situation? In what way might I alter my actions now? What feelings and reactions did I experience while interacting with this individual?

The second step is listening to and learning from others. Feedback from others that conflicts with self-image can produce anxiety. In response, the feedback is ignored or translated incorrectly to preserve self-image and reduce anxiety. However, this pattern of responding limits knowledge of the self and inhibits the ability to examine the appraisals of others, resulting in limited personal growth. Asking reflective questions enables the nurse to use feedback effectively. Helpful questions include “What feedback have I received today?” and “What is the other person trying to tell me now?” A person also can ask others directly for feedback. For example, a student nurse might ask another student how he or she comes across. The feedback

might be used to alter aspects of behavior that are ineffective or problematic before the student nurse asks a faculty member for evaluative feedback. Using clinical supervision and consultation with colleagues provides needed opportunity for reflection on practice. How the nurse comes across to the individual, family, or community is crucial to successful health promotion, making self-awareness and sensitivity to feedback essential.

The third step is **self-disclosure;** sharing aspects of the self enriches interpersonal life. Through self-reflection/self-disclosure, people come to know themselves better because they have exposed their thoughts, actions, and feelings for examination with others. Self-disclosure is an indicator of a healthy personality and a strategy for developing one (Jourard, 1971; Stuart, 2012). Self-disclosure by one person tends to trigger self-disclosure by another in a reciprocal pattern of interaction. Therapeutic interactions characterized by reciprocity involve a mutual exchange—a pattern of communication between the nurse and an individual, not a one-way intervention from the nurse to the other person. Traditionally, clinicians have been wary of self-disclosure because it may cross a boundary from a professional to a personal relationship. Additionally, the nurse's self-disclosure might burden the individual and shift the focus of attention from the individual to the nurse. Although these guidelines are considered so as to prevent excessive or inappropriate self-disclosure, appreciation that self-disclosure occurs within all human interactions is needed. Baldor (2011) found that experienced psychiatric nurse practitioners and clinical nurse specialists identified appropriate self-revelation as an effective component of the therapeutic relationship. Self-disclosure was seen as effective when thoughtfully applied on the basis of the client's developmental stage, the length of the relationship, client need, and boundary strength. Effective self-disclosure was context dependent and related to relational skill of the experienced or expert nurse. Implications included participants' belief that self-disclosure by the clinician is unavoidable and that it can contribute to strengthening or weakening the therapeutic alliance. Thus evidence supports that nurses are not blank screens, robots, or technicians delivering care;

individuals value nurses who engage in interactions as real people and who are willing to share information about themselves appropriately and thoughtfully. Seeking consultation from a colleague is helpful whenever a concern arises regarding the limits of appropriate self-disclosure.

Practical reflection (i.e., self-reflection) involves deliberating on one's own thoughts and recollections of events to understand them and to take needed corrective action. In reflection, thoughts are interpreted or analyzed. The process tends to be triggered by a seminal or meaningful event or situation, and the process results in increased understanding or awareness. These insights can then be used in the future when one is faced with a similar event or situation to implement a planned approach. Research outcomes show that self-reflection is associated with lowered practice stress and increased competence among nursing students (Pai, 2015). The process of practical reflection dovetails with steps toward self-awareness previously described and offers complementary helpful tips. First, the nurse recalls an incident when something went wrong. Then the nurse experiences the incident again by remembering images and by privately retelling events, statements, outcomes, and associated emotions. Next, the nurse interprets the story of communication that failed by examining expectations, ideals, goals, influences, personal actions, and others' actions that occurred during the event. The last step involves honest inspection of the nurse's own role in the story. Insights gained may be applied to prevent repetition of the problem and to plan future action (Box 4-4).

Box 4-4

Components of the Self

- The *public self,* which is shown to others.
- The *semipublic self,* which is seen by others but may be outside the individual's awareness.

- The *private self,* which is known to the individual but is not revealed to others.

- The *inner self,* which is the unconscious portion not known even to the individual because it has anxiety-provoking content.

Why is it important for a nurse to clarify personal values and increase self-awareness? The nurse's values and self-understanding influence behavior. The self is the nurse's greatest tool: to use the self effectively, the nurse must be fully aware of how it functions. Thus reflection and self-awareness guide the nurse's practice framework. In addition, sensitivity to individuals' perspectives is required to build a collaborative partnership, the cornerstone of the nurse-person relationship. Helping individuals to explicate their values and direct their actions accordingly toward health-related goals embodies patient-centered care as defined by Quality and Safety Education for Nurses (QSEN, 2012): "Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs." In today's multicultural society, sensitivity to one's values as a health care provider and those of persons for whom we care becomes crucial to delivery of person-centered effective care (McCaffrey & McConnell, 2015).

The Communication Process

The **communication process** is the forum for all thought and relationships shared among people. In conjunction with the use of scientific and technological advances, communication is an essential tool for the nurse to engage in health-promotion interventions. Communication is the foundation for any professional relationship. Nurse-patient communication plays a vital role in the formation and development of the nurse-patient relationship. It is the glue that connects individuals' learning and satisfaction with care (D'Antonio et al., 2014; Tejero, 2011). Communication is an information exchange between individuals through shared symbols and signs and commonly understood behavior (Ruesch & Bateson, 1987). This exchange involves all the modes of behavior that an individual uses, consciously or unconsciously, to affect another person. Communication includes the spoken and written word and nonverbal communication (gestures, facial expressions, movement, body messages or signals, and artistic symbols). Furthermore, communication errors between clinical providers and individuals or their proxies as well as ineffective communication among practitioners have been identified as a major source of personal and health care delivery safety problems (Box 4-5).

Box 4-5

Use Strategies for Communicating Clearly/Enhance Health Literacy Capacity

- *Greet patients warmly:* Receive everyone with a welcoming smile, and maintain a friendly attitude throughout the visit.
- *Make eye contact:* Make appropriate eye contact throughout the interaction. Refer to Tool 10: Consider Culture, Customs and Beliefs for further guidance on eye contact and culture.

- *Listen carefully:* Try not to interrupt patients when they are talking. Pay attention, and be responsive to the issues they raise and the questions they ask.

- *Use plain, nonmedical language:* Don't use medical words. Use common words that you would use to explain medical information to your friends or family, such as stomach or belly instead of abdomen.

- *Use the patient's words:* Take note of what words the patient uses to describe his or her illness and use them in your conversation.

- *Slow down:* Speak clearly and at a moderate pace.

- *Limit and repeat content:* Prioritize what needs to be discussed, and limit information to three to five key points and repeat them.

- *Be specific and concrete:* Don't use vague and subjective terms that can be interpreted in different ways.

- *Show graphics:* Draw pictures, use illustrations, or demonstrate what you mean with three-dimensional models. All pictures and models should be simple, designed to demonstrate only the important concepts, without detailed anatomy.

- *Demonstrate how it's done.* Whether doing exercises or taking medicine, a demonstration of how to do something may be clearer than a verbal explanation.

- *Invite patient participation:* Encourage patients to ask questions and be involved in the conversation during visits and to be proactive in their health care.

- *Encourage questions:* Refer to Tool 14: Encourage Questions for guidance on how to encourage your patients to ask questions.

- *Apply teach-back:* Confirm patients understand what they need to

know and do by asking them to teach-back important information, such as directions. Refer to Tool 5: Use the Teach-Back Method for more guidance on how to use the teach-back method.

Increasingly, communication is electronic. **Telehealth**, mobile health (**mhealth**), or Internet health (**ihealth**)—the use of telecommunications and data technologies to deliver health care services, including assessment/diagnostic services, treatment, consultation, and health information across platforms—is rapidly growing as a communication/intervention system. Such electronic communication can encompass the spoken and written word, and nonverbal forms of communication. Using technology to engage individuals in clinical communications is already in place, with potential for future development, and brings its own challenges (Haskey et al., 2015). Issues of health literacy, as discussed later in this chapter, including access, technology competence, and sensory capacity (such as eyesight and hearing), influence the effectiveness of telehealth as a communication medium.

Thus clear communication is a major component of promoting an individual's, a family's, and a community's safety and quality care. Yet the format and interface differ from the modes of human communication available until the latter part of the 20th century and the 21st century, and changes will be exponential in the years to come. (For additional discussion, see Box 4-6: Innovative Practice.) Social determinants of health can play a crucial role in access to and the effectiveness of Internet-based health information and intervention delivery. Evaluation of Internet-based health education and intervention systems, including access, is a critical goal for translation of research to practice.

Box 4-6

Innovative Practice

Telehealth/mhealth/ihealth: Therapeutic Relationships in the Age of the Internet

Technological advances have produced rapid changes in communication. Automatic teller machines have replaced human tellers at banks for routine transactions. Voicemail rather than a receptionist routinely answers calls, and messages are recorded electronically. An electronic response to many calls directs the caller to a series of options that may not even include speaking to a person. E-mail, instant messaging, and "texting" are ubiquitous. Information in many areas is now available via access to a computer and an Internet connection. Wireless Internet (WiFi) access is increasingly used as a perk to lure customers to the local coffee spot and to ease passengers' irritation during long flight delays. Nurses use electronic records and communicate updated information via handheld devices.

In the past decade, we have witnessed exponential increases in computer penetration (Thielst, 2010). Such technology can improve work and expand capabilities. Who would prefer to use a traditional typewriter to prepare papers and documents after mastering a word-processing program? Yet many issues deserve examination as we move into the age of telehealth.

Telehealth or mhealth or ihealth—the use of telecommunications and data technologies to deliver health care services, including diagnostic services, treatment, consultation, and health information—is now omnipresent. Rather than replacing traditional care, telehealth is best understood as a complementary approach to long-distance care delivery, and faster and easily delivered contact. Telehealth has the potential to expand access to care, particularly for individuals receiving home care and those in remote areas, and to contain costs (Luptak et al., 2010). Moreover, the concept of telehealth also encompasses remote teaching, conferencing, and consulting

(Ackerman et al., 2010).

Technological advances have produced benefits; however, technology can also reduce the need for direct interpersonal contact. Barriers to use include the need for financial investment to establish networks, inadequate reimbursement mechanisms, potential risks to confidentiality with electronic transmission, and licensure issues when care is transmitted across state lines. Challenges include conducting systematic evaluation of outcomes and cost-effectiveness, and ensuring that individuals' economic status and health literacy do not constrain access.

Perhaps the most important threat is that care can become impersonal when face-to-face contact is replaced by an electronic interface. Thus preserving core nursing values as electronic care systems are created, tested, and implemented is a crucial goal. Innovative practices to safeguard core professional values in the emerging age of telehealth include:

- The avoidance of a “one size fits all” approach through individualized or tailored algorithms and design features specific to the system's use. Moreover, clinician behaviors that facilitate a patient-centered style of communication include using open-ended questions, building partnerships, sharing decision-making and information, providing counseling, and using statements of concern, agreement, and approval. This style more successfully addresses individual needs and is associated with greater patient satisfaction, better psychosocial adjustment, and improved health outcomes. Adding opportunities for on-line questions and answers or an open electronic or telephone chat with a clinician can facilitate tailoring in this delivery approach. Text and/or e-mail prompts can also facilitate adherence to care. Also, providing user-friendly access, education/instruction, and tracking/monitoring use and problems are necessary ingredients for high user satisfaction (Young et al., 2011).

- The development and maintenance of therapeutic relationships by inviting exchanges between the nurse and the person; for example,

by creating a series of layered screens that first introduce the nurse (visually and with a biography) and later invite exchanges, feedback, and sharing of experiences and stories from individuals.

- The fostering of individual autonomy by building components that encourage decision-making, problem-solving, and knowledge development that are timely and specific to the health problem and stage of treatment or management.

- The creation of flexible technology applications that work across a variety of platforms (e.g., computer, smartphone, tablet).

Consider the following questions about telehealth:

- What effects do technological changes have on the therapeutic relationship?

- Will face-to-face interaction become a rare occurrence? In the future, might therapeutic interactions occur primarily via technology, such as voicemail, the Internet, and video-recorded transmission? What advantages and disadvantages will appear with the increasing use of technology in nursing practice?

- What creative approaches may evolve using technology in therapeutic relationships?

- How can electronic communication systems be used in disaster preparedness to alert people at risk and direct actions to increase safety when a human-caused or natural disaster is suspected, imminent, or in progress?

In nursing, communication is the cornerstone of a positive nurse-person relationship. Communication refers to a set of strategies and actions to enhance reciprocity, mutual understanding, and decision-making. Focusing the clinical discussion on the person's story rather than a version reformulated by the provider is essential to person-centered communication. Box 4-7 highlights strategies associated with person-centered communication based on evidence from the research literature.

Box 4-7

Strategies Associated With Person-Centered Communication

- Permitting people to tell their stories in their own words and chronology.
- Using a conversational interviewing style.
- Being friendly through humor and social conversation, and nonverbal cues such as smiling.
- Eliciting people's views, perspectives, thoughts, wishes, goals, values, and expectations.
- Inquiring about the nature of the person's life.
- Attending to the person's needs.
- Avoiding overemphasis on technical aspects of care and tasks.
- Not being too busy to talk.
- Responding to cues concerning emotional issues and problems.

- Giving information about self-care and participation in decision-making.
- Developing mutual understanding.
- Creating collaborative health care plans.
- Showing empathy and concern for the individual's well-being.
- Connecting with individuals through humor, touch, and selective self-disclosure.
- Tuning in to individuals' preferences and style.
- Attending to and advocating individuals' needs.
- Maintaining confidentiality.

Sources Dziopa, F., & Ahern, K. (2009). What makes a quality therapeutic relationship in psychiatric/mental health nursing: A review of the research literature. *Internet Journal of Advanced Nursing Practice, 10*(1), 1–19; Bolster, D., & Manias, E. (2010). Person-centered interactions between nurses and patients during medication activities in an acute hospital setting: Qualitative observation and interview study. *International Journal of Nursing Studies, 47*(2), 154–165.

Considerable evidence supports the effectiveness of these strategies. Research study results showed that nurses communicate effectively when they use a person-centered approach or nurse-person relational approach consisting of their being attentive, caring, accepting, empathetic, friendly, comfortable, calm, interested, sincere, and respectful (Doss et al., 2011; Tejero, 2011). Although these strategies sound simple and basic, such appraisals are noticeably absent in many instances and their presence is essential to quality nursing care (Box 4-8: Research for Evidence-Based Practice). Furthermore, research findings have indicated that nurses seek communication with individuals that supports openness and engagement of both the nurse and the person to form a bonding factor between them (Tejero, 2011).

Box 4-8

Research for Evidence-Based Practice

The Mediating Role of Nurse-Patient Dyad Bonding in Patient Satisfaction

Study Overview

Using a correlational path analytical research design, Tejero (2011) examined the direct and indirect relations of nurse characteristics and patient characteristics to patient satisfaction, as mediated by nurse-patient dyad bonding. A sample of 210 nurses and 210 patients from medical surgery, obstetrics, gynecology, otolaryngology, and ophthalmology units, the trauma ward, and medical intensive care units participated in the study. Characteristics of the nurses and patients were gathered through observation, interview, and medical record review. Instruments were used to measure nurse-patient bonding during observation and to measure patient satisfaction with nursing care in the interview. In addition, a checklist was used to collect information on patient complexity, vulnerability, and predictability as well as information on nurse clinical judgment and facilitation of learning.

Results

The results confirmed the importance of the nurse's role in the formation of a therapeutic dyadic relationship that results in patient satisfaction—a critical part of quality outcomes in health care. Openness and engagement of nurses during interactions were significantly and positively correlated with patient satisfaction. Path analysis showed that nurse facilitation of learning was particularly important in mediating nurse-patient dyad bonding. Nurses' efforts to educate and provide information to patients displayed openness and engagement, which leads to openness and engagement from the patient. The manner, tone, and emotion of the nurse were also shown to affect patient satisfaction.

Implications

Formation of nurse-patient therapeutic dyadic relationships plays a major role in the quality of patients' experiences. Tejero (2011) stated that a key implication is that the nurse is the healthy individual in the dyad and clinical expert in the interaction, who is obligated to initiate and steer the dyadic relationship toward a therapeutic bond. The findings of this study showed that nurse facilitation of patient learning should be emphasized in practice and in teaching students so as to provide evidence-based practice and improve patient satisfaction.

Function and Process

The following are core functions of communication:

- To obtain and send messages and to retain information.
- To use the information to arrive at new conclusions, to reconstruct the past, and to look forward to future events.
- To begin and to modify physiological processes.
- To influence others and outside events (Ruesch & Bateson, 1987).

Communication transmits information, both interpersonally and intrapersonally, and it provides the basis for action.

The process of communication consists of four components (Watzlawick et al., 1967). Nurses must be able to diagnose communication difficulties in any of these components. **Input** involves taking in information from outside the individual or group. Once taken in, input must be transformed in some manner to be used. For example, symbols must be translated into words to transmit ideas. The flow and transformation of processed input refers to the way information is analyzed and stored within the individual, or the way it is transmitted from person to person within a human system (group or family) before communication with the external environment occurs. The outcome of information processing, **output**, involves

further exchange with the environment or the other person. A new information exchange is triggered at this point in the cycle by the response called **feedback**, a monitoring system through which the person or group controls the internal and external responses to behavior (output) and accommodates these responses appropriately. A feedback **loop** shows the dynamic nature of communication. Each piece of communication is both a stimulus designed to elicit a response and a response to a different stimulus.

When interpersonal communication is analyzed, two types of feedback can be identified: positive (encouraging change) and negative (encouraging homeostasis or no change). Parents' commands to a young child illustrate these types of feedback: positive, "Try that again; you almost had it," and negative, "Don't touch that; it's hot." The first statement shows the parent's attempt to encourage the child to continue new behavior; the second illustrates an effort to curtail undesired behavior. Rather than meaning "good" or "bad," positive feedback and negative feedback refer to promotion of system change and stability, which is the process of balancing the direction and magnitude of change. Both types of feedback are needed, depending on the situation.

The situational context of communication is important. The context of communication is the setting's physical, psychosocial, and cultural dimensions. It includes the relationship between the sender and the receiver; their previous experiences, feelings, values, cultural norms, age, and developmental stage; and the physical location.

Types of Communication

All human communication occurs in three forms: verbal, nonverbal, and metacommunication. Each affects the meaning and influences the interpretation of the message.

Verbal Communication

Verbal communication is the transmission of messages using words, spoken or written. As symbols for ideas, words impart meaning

defined by a specific language. Communicating with language is a critical ability.

People who are deaf or hard of hearing often use sign language to communicate. Signs, similarly to spoken or written words, are used consistently to represent a particular meaning. Words may also be spelled out through finger spelling in a manner parallel to written communication. Braille assists blind and visually challenged people to read. Touch is used to interpret markings that represent letters and words. Sign language and braille blend aspects of verbal and nonverbal communication, but both forms of communication transmit meaning through a consistent language system.

Verbal communication with people who speak a different language poses a challenge. As societies become increasingly multicultural, assistance from specially trained interpreters is essential for the provision of culturally competent care. Confidentiality issues, the complexity of health information, and the need to validate understandings and reach mutual decisions make it inappropriate to use untrained personnel or relatives to interpret what is meant simply because they are available.

The importance of language development is apparent in its three functions: informing the person of others' thoughts and feelings; stimulating the receiver of a message by triggering a response; and serving a descriptive function by imparting information and sharing observations, ideas, inferences, and memories (Watzlawick et al., 1967). The ability of verbal communication to fulfill these functions is influenced by many factors, including the communicator's social class, culture, age, milieu, and ability to receive and interpret messages.

Nonverbal Communication

Nonverbal communication or language encompasses all messages that are not spoken or written. The channels of nonverbal communication are the five senses. Movement, facial and eye expressions, gestures, touch, appearance, and vocalization or paralanguage all constitute nonverbal modes of communication (Blondis & Jackson, 1982). Although all communication has the

potential of being misunderstood, nonverbal communication is particularly subject to misunderstanding because it does not always reflect the sender's conscious intent and is highly influenced by culture. Nonverbal messages also tend to be nebulous, without specific beginnings and endings.

Body motion or kinetic behavior includes facial expression (or facies), eye movements, body movements, gestures, and posture (Blondis & Jackson, 1982). When observing facial expression, the nurse notices the affect or emotion that is communicated. Does the person appear happy or sad; alert, distracted, or sleepy; contented, agitated, angry, or anxious? The degree of emotion expressed should also be noted. Does the person's face express what generally is considered an excessive degree of feeling for the situation, too little, or none at all? Eyes, in conjunction with the movement of other facial muscles, move in ways that convey affect. Eye contact conveys messages of interest or trust; lack of eye contact can imply lack of interest or anxiety; constant eye contact can send a message of hostility.

All of these nonverbal messages are culturally and situationally bound. Nonverbal behavior, particularly facial and eye expressions, is contextual. For example, in certain circumstances and cultures, avoidance of direct eye contact between some people can be a sign of respect. Yet in other situations and cultures, it can be interpreted as indicative of disinterest, avoidance, or disrespect. Therefore interpretation requires a cultural lens.

Sign language combines features of both nonverbal and verbal communication. Sign language involves nonverbal communication because, although it uses symbols that are communicated through specific signs, these are enhanced by facial expressions and body postures. However, sign language shares many aspects of verbal communication. It has syntax and grammar, words may be spelled out, and a standard meaning is assigned to specific signs to create symbolic language, just as words share common definitions.

Importance of nonverbal communication.

Nonverbal communication has great power to transmit information

about another's thoughts and feelings; therefore careful observation is essential. Even silence can be very revealing. The significance of nonverbal communication is best captured by the axiom “actions speak louder than words.” Nurses' nonverbal messages that communicate distance from the person, or signal an unfriendly or uncaring attitude, thwart development of a therapeutic relationship (Henry et al., 2011) and thereby render health-promotion efforts unproductive.

Metacommunication

Besides verbal and nonverbal communication, a phenomenon called **metacommunication** refers to a message about the message. Watzlawick and colleagues (1967) described metacommunication as the impossibility of not communicating: that is, “one cannot not communicate.” Persons transmit a message about what is being communicated even when words are not spoken.” Metacommunication is the relationship aspect of communication. In a sense, metacommunication involves reading between the lines or going past the surface content of the message to glean nuances of meaning. When the content and the relationship aspects, or metacommunication aspects, of a message are incongruent, interpreting the communication accurately may be difficult, leaving the receiver uncomfortable and confused.

Group Process

In group settings, a special type of metacommunication is called **process**. A basic principle of group theory states that all communication has content and process. Content is what is said; process is the relationship aspect of what is communicated. Group process occurs during every group encounter. Staff meetings and clinically oriented psychoeducation, therapy, and counseling groups always involve group process. For example, consider two individuals in a smoking cessation group who always support each other by agreeing with each other and offering comments or criticism to any

group member who disagrees. Although this pairing between the individuals offers them some protection from anxiety that may result from self-examination and feedback, it isolates them and curtails feedback from others. Examination of this group process is an essential task. The nurse leader and participants can transform this problematic situation into a learning opportunity by identifying the pattern and pointing out the behavior after it has occurred frequently; helping the pair and other group members consider what needs are being met through this pattern; looking at each person's role in fostering this process (e.g., why other group members have failed to confront the pair); and discussing potential outcomes of changing the behavior. These steps can be applied in clinical situations when greater self-understanding is a goal.

Effectiveness of Communication

Understanding what makes communication effective improves the nurse's ability to assess needs and to intervene successfully to promote individuals' health. Steps to functional communication include firmly stating the case, clarifying the message, seeking feedback, and being receptive to feedback when it is received. Implementing these steps to functional communication between nurses and individuals, and between nurses and other care providers, is essential to ensure patient safety and quality care (QSEN, 2012).

To state the case, the sender needs to make the content and the metacommunication congruent; when they conflict, the message is confusing. For example, a nurse is angry with a colleague for making statements to an administrator that undermined the nurse's plans for reconfiguring a health-promotion program in their agency. When the nurse had a chance to speak with this colleague, they exchanged pleasantries without mention of what the nurse thought about the colleague's statements to the administrator. When the colleague asked if something was bothering the nurse, the nurse responded that nothing was wrong. The colleague senses that the nurse's verbal and nonverbal communication did not match; in other words, the content of the message and the metacommunication were incongruent. The

colleague was left feeling uneasy, and the nurse failed to express his or her thoughts or to take effective action to rectify the perceived problem with the colleague. To make the communication functional, the nurse needed to bring thoughts and feelings into awareness and reflect on the intended message. Once these steps have been accomplished, the message's content and metacommunication can be adjusted to match, and the nurse's communication is likely to be effective. This example typifies ineffective communications.

To clarify the message, the sender must give a complete message. Important features should be emphasized and specifics of any request must be stated, not assumed. The message's importance must also be indicated. To illustrate this, a woman mentions to her nurse that it is nearly June. The nurse responds that he has noticed how warm the weather is becoming. On the surface, this communication may seem functional until the intent of the woman's message is considered. She meant to imply that June is the 5-year anniversary of her remission from cancer, and she hoped that her nurse would somehow know that she wanted him to comment on the significance of this anniversary. To make this communication functional, the woman needed to expand the message (e.g., "My anniversary after cancer treatment is coming up") and then clarify her wish to hear a sensitive response from the nurse (e.g., "This anniversary marks the goal for you to be cancer-free." "What will you do to celebrate?"). Additionally, she needed to show how important the message was (e.g., "I'd really like to do something special to mark this date"). If the nurse had been attuned to the metacommunication in this exchange, he could have clarified this woman's intent and met her need for recognition and dialogue.

One technique for clarifying and qualifying messages is called the "I" statement. Use of "I" statements helps the sender state what he or she wants, feels, thinks, or plans (including likes and dislikes). For example, "I felt unimportant when you forgot to recognize this anniversary" is an "I" statement that the person could have used to communicate effectively. Soliciting such "I" messages is a therapeutic technique to be encouraged.

Questions can clarify and qualify messages, depending on the type of question asked. Open-ended questions tend to elicit descriptive responses rather than one-word answers. For example, the question "Tell me what you did for exercise this week" is likely to yield a more elaborate description of a health behavior from a person than the question "Did everything go okay with your exercise plan?" However, direct questions that seek a one-word answer are useful when a specific piece of information is sought. "Did you spend 15 minutes or more walking today?" may be a better approach than "What was your activity like today?" when it is important to discuss and promote minimal exercise requirements. Also, for individuals having trouble expressing more than the simplest thoughts, asking direct questions that call for brief replies can be helpful, such as "Did you eat breakfast?" This approach is particularly useful with people who are depressed, regressed, cognitively impaired, or unable to handle complex information or communication at a particular time, or when a specific yes/no response is needed.

Seeking feedback is another element of functional communication. Consensual validation, confirming that both the sender and the receiver understand the same information, calls for the use of the clarification skills just described. In family communication, the parent, as the sender, should model this behavior for children by asking the child, as the receiver, to explain his or her sense of the message and how to ask the sender for further explanation. For example, "I want you to clean your room" (message from parent) can be followed by "Tell me how you think you will do that" (validating that the child and the parent agree about what the task entails). This style of seeking validation can be adapted to nurse-nurse or nurse-interprofessional exchanges between colleagues and to therapeutic interactions, and is critical to effective clinical care (Institute of Medicine, 2010). Such confirmation in communication is also essential when health-promotion interventions are being provided. Without validating that the person understands the information and its importance, and that the person has a behavior plan to follow, health-promotion efforts are likely to fail. Moreover, failure to validate understanding is a

significant risk to patient safety (QSEN, 2012).

Being open to feedback is also crucial. A "no questions" attitude blocks functional communication, whether in the home, classroom, or clinical setting. Children, students, individuals, and even other nurses may be afraid to question anyone in authority or may assume that the person should magically know what is intended or expected. For example, a person may avoid confronting a nurse who fails to explain the clinical plan and then communicates that the person should know how to follow through. Statements by the sender such as "Tell me what you think" and "What is your understanding of what I said?" are helpful in eliciting confirmation of understanding and feedback.

Receiving and sending messages involve many of the same processes. Evaluation of the intent of the message, both the content and the metacommunication, is the first step. The receiver frequently needs to seek clarification and validate understanding of the message for communication to be effective. Clarification of expectations, active exchange of information, power sharing, and negotiation will enhance the quality of nurse-person communication. The outcome is a nurse-person relationship based on trust and partnership (Doss et al., 2011), critical ingredients of patient-centered care (Institute of Medicine, 2010).

Interprofessional Communication and Teamwork

Interprofessional communication and teamwork for care design and delivery involve cross-disciplinary education and practice approaches that are now widely promoted as essential to an effective health care system (Lyons et al., 2016; Thistlethwaite, 2012). However, instruments to help students and clinicians to hone their observations of teamwork behaviors have been lacking. The Jefferson Teamwork Observation Guide is an easy-to-use short tool, with evidence of reliability and face and predictive validity, for observation of teams in action to identify behaviors, including communications indicative of good teamwork (Lyons et al., 2016). The Jefferson Teamwork Observation Guide is a helpful instrument for nurses to use to recognize, observe, and then implement the behaviors that comprise

good teamwork and communication.

Factors in Effective Communication

Listening

Effective listening, an important part of communication, is more than passively taking information. Effective listening is actively focusing attention on the message. Asking questions to explore what is meant helps the listener reach an accurate assessment of the message's meaning.

Many forms of nonverbal communication have been identified that, from a Western or European perspective, commonly convey that the person is listening. These nonverbal communications include direct gazing and eye contact, head nodding, orienting one's body to maintain interpersonal closeness, leaning forward, making facial expressions such as eyebrow animation and smiling, and using brief verbal statements that indicate interest, such as “Please go on” or “Tell me more about that….”

For behavior to communicate that the person is listening also depends on the context and intensity of the activities, and the cultural norms of each person. For example, leaning close to a person might be interpreted as intrusive. Yet the same behavior could be seen as a sign of support, depending on the context and perspective of those involved. Sensitivity to nuances in communication and validation of meaning can be particularly helpful strategies when the nurse and the person come from different cultural backgrounds.

Reciprocity, the patterning of similar activities within the same interval by two people, can help the nurse communicate a listening stance in an effective way. When the nurse matches nuances of the individual's type and style of behavior, the chances that the person will interpret the nurse's behavior as an indication of active listening are increased, and the likelihood of misinterpretation is reduced. Nurses can enhance the quality of their communication, even when encounters are brief, by attending to reciprocity in their interactions and by validating whether or not reciprocity is associated with shared

interpretations of meaning.

Poor listening blocks the nurse's understanding of the person. The nurse's failure to listen may be caused by anxiety; focus on other demands; lack of experience, which leads to excessive talking by the nurse; preoccupation with personal thoughts; or lack of practice. The importance of focusing on the individual's needs and concerns through effective listening is a recurrent theme in research concerning therapeutic interaction (Doss et al., 2011; Shipley, 2010; Stuart, 2012) and a cornerstone of patient-centered and safe care (Institute of Medicine, 2010; QSEN, 2012).

Flexibility

Flexibility is a balance between control and permissiveness. In "overcontrol," every message is monitored. In exaggerated permissiveness, anything can be communicated in any way. For communication to be functional, rules are needed about what is appropriate, without rigid prescriptions that inhibit meaningful interchange. For example, the guideline that nurses will not answer questions concerning intimate details of their lives sets an appropriate limit; however, this does not mean that nurses should refuse to answer any question about themselves.

Silence

Silence between people is often uncomfortable for the nurse who is somewhat insecure about what should occur during a therapeutic encounter. However, silence can be beneficial when used carefully. When one is seeking a verbal response, silence can be perceived as a lack of interest. At other times, silence allows individuals to reflect on what is being discussed or experienced, lets them know that the nurse is willing to wait until they are ready to say more, or simply provides them with comfort and support. Each situation needs evaluation and sensitivity. Rather than asking a flurry of questions to break the silence, the nurse allows the person time to decide when to comment or should make brief comments that do not demand answers, such as

“It can be helpful to take time to think about what we've been discussing.” Also, comments such as “Try putting your thoughts or feelings into words” and “I am here when you are ready to talk” can help the person to share these thoughts or feelings when silence is blocking rather than improving the communication.

Humor

Humor is part of being human; it relieves tension, reduces aggression, and creates a climate of sharing. Humor can block communication when it is used to avoid subjects that might be uncomfortable or when it excludes other people. Humor can also inflict emotional pain and communicate negative views or stereotypes about particular individuals or groups through teasing and jokes concerning race, ethnicity, culture, country of origin, occupation, age, sex, sexual activity, or other traits that stand out or are devalued. A direct response to the latent content or message in this type of humor is an effective way to curtail its use and minimize its effect. For example, a response that shows disapproval of the latent message such as “That kind of joke makes me very uncomfortable. I don't find it funny to describe [the specific group in question] that way, and I would like you to stop” will send a clear message and be likely successful in stopping the offensive communication. In contrast, for humor to be helpful the meaning of the humor must be understood and its purpose supportive to the individual. Clarification of the meaning should be used when there is doubt or concern.

Touch

Touch is an interesting means of nonverbal communication for nurses, who often touch individuals while administering care. The nurse's concern can be expressed by a gentle or soothing application of touch. Nevertheless, in some instances touch is inappropriate. For example, in interactions with individuals who have trauma histories or acute psychiatric disturbances, touch might be misinterpreted. A woman who has been raped might interpret touch during an examination as

an attack. Evaluation of the context and meaning of touch to the individual is based on knowledge of that person and interpretation of feedback. Informing the individual about the purpose of touching and asking for permission and feedback are useful techniques to avoid unintended distress or misinterpretation of touching in a clinical encounter.

Space

Space between communicators varies according to the type of communication, the setting, and the culture. Hall (1973) researched **proxemics**, the use of space between communicators, and identified four zones of space commonly used in interaction in North America; these are presented in Box 4-9 and Figure 4-1. It is critically important for nurses to be sensitive to how spacial zones vary across cultures when caring for persons from diverse backgrounds.

Box 4-9

Zones of Space Common to Interaction in North America

1. *Intimate space:* up to 18 in (45.5 cm); used for high interpersonal sensory stimulation (see Figure 4-1A)

2. *Personal space:* 45.5 cm to 1.2 m (18 in to 4 ft); appropriate for close relationships in which touching may be involved and good visualization is desired (see Figure 4-1B)

3. *Social-consultative space:* 2.7 to 3.6 m (9 to 12 ft); less intimate and personal, requiring louder verbal communication (see Figure 4-1C)

4. *Public space:* 3.6 m (12 ft) or more; appropriately used for formal gatherings, such as giving speeches (see Figure 4-1D)

Source Hall, E. (1973). *The silent language.* Garden City, NY: Doubleday/Anchor Press.

FIGURE 4-1 **A,** Intimate distance communication. **B,** Personal distance communication. **C,** Social-consultative distance communication. **D,** Public distance communication.

Understanding the appropriate distance for a given type of interaction helps the nurse to make nonverbal and verbal communication congruent and to avoid violating spatial norms. Awareness of cultural customs concerning distance is important in shaping communication and interpreting the behavior of others. When people from different cultures or groups communicate, there may be discomfort about the acceptable distance between them when

speaking. Recognition of differences helps the nurse adjust the distance and interpret the meaning of this nonverbal communication.

Many traits and components discussed in this chapter characterize functional communication. However, communication is a subtle and intricate process. Communication cannot be reduced to a set of parts and principles; its roles and nuances are far more complex and variable. Communicating by language and symbols is a special human ability. Healthy communication enables people to move from being alone to being together—clearly one of the crucial tasks of living. Effective communication is also the foundation for the helping relationship. Moreover, effective communication is essential to providing quality care and ensuring patient safety and well-being (QSEN, 2012).

Health Literacy

Clear communication improves the quality of health care encounters. **Health literacy**, the capacity to read, comprehend, and follow through on health information, is a critical component of health promotion. Yet nearly 9 out of 10 adults encounter problems using everyday health information to make good decisions about health (Institute of Medicine, 2011). To combat low health literacy, nurses can encourage individuals to ask three essential questions at every health visit (National Patient Safety Foundation, n.d.; Speros, 2011):

- "What is my main problem?"
- "What do I need to do?"
- "Why is it important for me to do this?"

Nurses also promote health literacy by creating a safe and comfortable environment, sitting to establish eye contact rather than standing when communicating, using visual aids and models to illustrate conditions and procedures, and verifying understanding of care instructions by having individuals then teach the content; that is, using "teach-back" as a strategy (Speros, 2011). Resources are available to help nurses and other clinicians to increase individuals' understanding of health information across health literacy levels. The

Agency for Healthcare Research and Quality (2015) *Health Literacy Universal Precautions Toolkit* provides easily accessible and highly useful resources to promote universal health precautions; that is, steps to take when clinicians assume that all persons may have some limitations in understanding health information and accessing health services. This toolkit provides evidence-based approaches for use from assessment to intervention. The toolkit suggests fundamental communication strategies to communicate clearly (see Box 4-5).

Three key factors regarding health literacy to consider are the educational level of the target audience or users; the reading/comprehension level for materials in on-line, verbal, or written format; and the native language of the target audience or users. A highly educated target audience generally has high health literacy because of strong command of the native language being used. Research evidence has shown that health information in use may be at a reading level above the comprehension level (i.e., at 9th grade level) of the users. The researchers recommended that quality be improved in materials and instruction, especially for those with low education/literacy skills (Ryan et al., 2014). Furthermore, nurses need to assess comprehension of all health information and instruction, particularly of complex medical/health information. Developing materials at the 5th or 6th grade reading level helps ensure that comprehension is very likely across wide ranges of the target audience. Word processing programs and on-line tools can evaluate the reading level of text. Published materials also are available to help in assessing and developing appropriate content (McKenna & Stahl, 2015). These available resources enable nurses easily to determine the reading level of all health and research materials, and to adjust the level by changing complex terms to more commonly used words with only one or two syllables and simplifying sentences to avoid complex construction with multiple phrases. Finally, adjusting word usage to avoid native colloquialisms will increase understanding among persons whose native language is not being used. Moreover, advocating the development and/or revision of existing materials to reach a 5th/6th grade reading level is an

appropriate nursing mandate.

In the emerging age of telehealth, developing strategies for confirming understanding and individualizing methods of communicating health information is increasingly important (see Box 4-6: Innovative Practice). Health information and even access to appointments are steadily shifting from face-to-face interaction to access by telephone via voice prompts and Internet-based formats. Many factors involved in health literacy can impair individuals' ability to understand and respond to audio and/or visual commands. Consider the array of commands involved in the typical automated telephone system involved in ordering a prescription refill from a typical pharmacy. The individual must select from a list of options; next, multiple numbers must be keyed in that represent prescription numbers listed in small print from a prescription label and birthdays in appropriate format; finally, a variety of confirmations must be entered. Persons with auditory, visual, language comprehension, and/or cognitive limitations may not have adequate capacity to manage such common health care technologies. Therefore technology competence becomes another component of health literacy to be considered.

The Helping or Therapeutic Relationship

A **helping or therapeutic relationship** is a process through which one person promotes the development of another person by fostering the latter's maturation, adaptation, integration, openness, and ability to find meaning in the present situation (Peplau, 1969; D'Antonio et al., 2014). The therapeutic relationship emerges from purposeful encounters characterized by effective communication. In this relationship the nurse respects the individual's values, attends to concerns, and promotes positive change by encouraging self-expression, exploring behavior patterns and outcomes, and promoting self-help (Doss et al., 2011). The therapeutic relationship is the foundation of clinical nursing practice (D'Antonio et al., 2014)—the essential element of quality care with every individual in every situation (QSEN, 2012). Techniques, technology, interventions, and contexts differ, but the relational aspect of nursing practice produces a cohesive unity, allowing each nurse to see people holistically and as unique individuals. Although many components of the helping relationship are most germane to relationships that extend over time, the essentials of the helping relationship apply to even brief therapeutic encounters.

No perfect profile or personality of a helping person exists. However, certain traits can be nurtured without thwarting the nurse's unique personality. These characteristics enable the nurse to be an agent of therapeutic care (Peplau, 1963; Stuart, 2012). Box 4-10 lists characteristics associated with therapeutic effectiveness.

Box 4-10

Characteristics Associated With Therapeutic Effectiveness

- Self-awareness and self-reflection
- Openness
- Self-confidence and strength
- Genuineness
- Concern for the individual
- Respect for the individual
- Knowledge
- Ability to empathize
- Sensitivity
- Acceptance
- Creativity
- Ability to focus and confront

Characteristics of the Therapeutic Relationship

No recipe is available for a successful therapeutic relationship. Techniques and concepts serve only as tools. As a nurse develops and evaluates a helping relationship, be it long term or brief in nature, the following guidelines may be useful.

Purposeful Communication

Purposeful communication means that the nurse focuses communication toward a particular goal. Social chitchat, communication without a goal, should not make up the bulk of therapeutic interaction. This does not mean that the nurse should never discuss a social topic; nonetheless, there should be some

purpose. For example, discussing the weather with a somewhat disoriented older adult individual serves the purpose of orienting that person to the environment. Discussing the Super Bowl with an avid football fan may provide valuable assessment data and engage the person in a current topic of social interest. Goals guide the nurse in focusing communication.

Rapport

Rapport is a harmony and an affinity between people in a relationship. By using many of the traits listed for helping a person, the nurse can establish an atmosphere in which rapport can develop. To let the person know that his or her concerns interest the nurse and that working together may alleviate some of his or her difficulties and encourage growth, it is important to be genuine, open, and concerned.

Trust

Trust is a necessary component of any helping relationship. Trust is the reliance on a person to carry out responsibilities and promises, based on a sense of safety, honesty, and reliability. Trust is an important component of partnership. The nurse promotes trust by modeling and structuring the relationship appropriately. The following strategies promote trust:

- Anticipating that the individual will do as promised.
- Clearly defining the relationship parameters and expectations, particularly the purpose and specifics of time, place, and anticipated behavior.
- Being consistent.
- Examining behaviors that interfere with trust.

Empathy

Empathy is the ability to understand another's feelings without losing personal identity and perspective. Empathic nurses draw on emotions and experiences that enable them to place themselves in the other

person's situation. While the person senses increasing understanding and acceptance from the nurse, the individual's distress decreases. Outcomes from research studies are building knowledge about the role that empathic nursing care plays in outcomes. Nurses learn behavioral approaches that enhance empathic relations with people through supervised experiential learning (Haskey et al., 2015). For example, nurses do not empathize by switching the focus of the interaction to themselves or by sympathizing (e.g., "I know exactly how you feel; that happened to me once"). Rather, they use clinical and personal experience to appreciate the individual's feelings and experiences: they try to imagine themselves in the person's situation. Using personal understanding based on some shared aspect of experience such as a loss while maintaining boundaries is the essence of empathy in the helping relationship. With empathic understanding, the nurse acknowledges the affective domain of personal experiences and uses this knowledge to appreciate the person's reactions. Empathy enables the listener to share human experiences as the basis for providing care.

Goal Direction

A helping relationship is special in its goal-directed nature. Although most human relationships focus on mutual benefit, a helping relationship exists solely to meet some need or to promote the growth of the recipient. Although the nurse may benefit from the interaction, the relationship is centered on the recipient.

Goals are formulated as desired individual behaviors/outcomes. Short-term goals are likely to be achieved within 10 days to 2 weeks; all other goals are long term. All goals should be stated in measurable terms and should focus on a positive change or on the decrease of problematic behavior/health indicators. Ideally, a person works with the nurse to establish goals. However, some individuals, such as those who are seriously ill, depressed, psychotic, or cognitively impaired, may be unable to establish mutual goals. When an individual is unable to negotiate appropriate goals, the nurse establishes realistic goals and shares them to the degree possible with the person, who is

free to participate or to reject efforts to reach these goals. In some circumstances when the care recipient is unable to collaborate regarding care decisions, then a family member or another designee/health care proxy may be the appropriate person for such communication.

Ethics in Communicating and Relating

Ethical decision-making is closely linked with the goal-directed nature of helping relationships. Ethical issues are present in human interactions whenever behavior may affect others, whenever actions involve conscious choices of methods and ends, and whenever actions can be evaluated in reference to standards of right and wrong (Holmes, 2014). Guidelines that may be adapted as ethical standards for interpersonal communication are highlighted in Box 4-11.

Box 4-11

Guidelines for Ethical Interpersonal Communication

Ethical interpersonal communication involves:

- Being aware and open to changing concepts of self and others.
- Attending to role responsibilities; individual sacrifice, when it is required to make a "good" decision; and emotions, while guarding against letting emotions be the sole guide of our behavior.
- Sharing personal views candidly and clearly.
- Communicating information accurately, with minimal loss or distortion of intended meaning.
- Communicating verbal and nonverbal messages with congruent meanings.

- Sharing responsibility for the consequences among communicators.
- Recognizing the multicultural context of all communication.
- Respecting the dignity of every person.
- Avoiding coercion and use of power in communicating.
- Being sensitive to gender and cultural contexts of communication and interpretation.
- Building context for intercultural dialogue that is open with conditions of security and mutual respect.
- Eliminating any elements of your communication that denigrates, stereotypes, or devalues clients.
- Facilitating open and accurate communication among professional groups, professionals, staff and families, clinical care unit and department staffs or administrators, and clinical care facilities.

Unethical communication involves:

- Purposefully deceiving.
- Intentionally blocking communication—for example, changing subjects when the other person has not finished communicating, cutting a person off, or distracting others from the subject under discussion.
- Scapegoating or unnecessarily condemning others.
- Lying or deceiving that causes intentional or unintentional harm.
- Verbally “hitting below the belt” by taking advantage of another's vulnerability.
- Violating Health Insurance Portability and Accountability Act rules

concerning protection of personal health information.

Frequently the nurse may wish to set goals that the individual does not want to reach; the nurse must remember that the problem belongs to the person, as does the choice of care alternatives. The nurse assists the individual in decision-making, with the decision based on the individual's value system. However, the nurse should not take a laissez-faire approach and avoid assisting the person. The nurse's responsibility is to help the individual to examine values, identify conflicts, and prioritize goals and desired health care outcomes. Action follows from understanding values and the best available information. Both the individual and the nurse must bring interpreted facts and personally clarified values to the interaction to establish goals. Recognizing this interplay, the nurse must clarify personal values, subsequently respect the individual's rights, and act to support and protect the integrity of the person, family, group, or community.

Ethical communication also involves safeguarding protected health information. The individual's right to privacy motivated the passage of the Health Insurance Portability and Accountability Act in 1996. Individually identifiable health information is defined as (US Department of Health and Human Services, 2003):

Information protected by law and includes demographic data, that relates to: the individual's past, present or future physical or mental health or condition, the provision of health care to the individual, or the past, present, or future payment for the provision of health care to the individual, and that identifies the individual or for which there is a reasonable basis to believe can be used to identify the individual. Individually identifiable health information includes many common identifiers (e.g., name, address, birth date, Social Security Number).

Sharing personal health information (PIH) can be understood on the basis of "need to know" so as to care for the person. Stuart's (2012) concept of the circle of confidentiality provides a helpful guideline to nurses. "Within the circle, patient information may be shared. Those

outside the circle require the patient's permission to receive information. Within the circle are treatment team members, staff supervisors, health care students and their faculty (only if they are working with the patient), and consultants who actually see the patient." Adhering to the rules concerning protection of identifiable health information is both an ethical and a legal requirement for the nurse.

Therapeutic Techniques

Occasionally, clinicians who are novices in establishing helping relationships assume that they are bound to "say the wrong thing" and cause terrible damage to the person, or that they will learn some magical phrases and questions to create instant rapport. No nurse or other professional is so powerful that a "wrong word" will destroy the individual's self-concept or self-esteem. Even people with physical and emotional problems are resilient and have coped, at least to some degree, with a lifetime of stresses. Alternatively, no magical saying exists that the nurse can always plug into an interaction to communicate successfully. Although some techniques are often useful, they must be applied with purpose, skill, and attention to the individuality of each person and to the context of the interaction. The following techniques therefore should be viewed as guidelines, rather than prescriptions, for effective shaping of the therapeutic relationship.

Focus on the Individual

The first step to therapeutic communication is focusing on the individual and the reason that the interaction is occurring. The nurse is not the focus; the person is. Although an overly business-like style fails to communicate concern and support, delving into one's own personal life to the extent that it diverts attention from the other person's concern is also problematic. Avoiding nurse-directed conversation can be difficult; a useful rule of thumb is to answer or respond to obvious questions and to switch the focus back to clinical

concerns when other questions are asked. For example:

Individual (looks at female nurse's wedding ring): "Are you married?"

Nurse: "Yes, I am."

Individual: "What does your husband do for a living?"

Nurse: "Rather than get distracted by a discussion about me, let's get back to planning how you will manage at work."

Keeping focus on the person's concerns includes identifying the portion of the message that is clear and relevant to the purpose of the interaction, seeking validation, and helping the individual to clarify the rest of the message.

Help the Individual to Describe and Clarify Content and Meaning

Too often the nurse rushes to offer an interpretation of the nature of the problem and quickly follows up by suggesting a solution. Solving problems efficiently makes the nurse feel effective, important, and powerful; however, the person's needs may not be met. A crucial step in using the therapeutic relationship effectively is to assist the individual to describe a particular experience or concern. Description is enhanced when the nurse prompts the person to clarify the description and interpret its meaning.

Use of who, what, where, and when questions helps the person to clarify and expand the content and meaning of what is communicated. Phrases such as "tell me," "go on," "describe to me," "explain it to me," and "give me an example" are also likely to elicit description of important content and to diminish distracting generalizations and abstractions. By seeking feedback, the nurse helps the individual to explain the meaning further. In clarifying the meaning, the nurse should avoid threatening, detective-like questions. Questions that begin with "why" often increase the person's anxiety because they

demand reasons, conclusions, analysis, or causes (Peplau, 1964). Reformulating questions to obtain descriptive data first and then helping the individual to analyze links among events, thoughts, feelings, actions, and outcomes is generally a more helpful approach.

A problem-solving approach by the nurse assists the person to describe and clarify the content and meaning of experience. Sequential steps help the individual to explain events, to change circumstances and responses that interfere with health, and to solve problems (D'Antonio et al., 2014; O'Toole & Welt, 1989; Peplau, 1963). This problem-solving approach can be adapted for use in health promotion to assist the person in problem-solving by working through the steps outlined in Box 4-12: Quality and Safety Scenario. These steps are a useful guideline for keeping the focus of concern on the individual and his or her definition of the problem. Rather than telling the person what is wrong and how to fix it, the nurse's primary goal is helping the person to describe the problem and formulate solutions in partnership. The cyclic nature of the process is illustrated in Figure 4-2.

Box 4-12

Quality and Safety Scenario

Steps in Promoting Problem-Solving

Describe the Experience or Event of Concern

Helpful Verbal Nursing Strategies

"Tell me what happened."

"Describe the experience to me."

Analyze the Parts of the Experience and See the Relationships to Other Events

Helpful Verbal Nursing Strategies

"What meaning does this have for you?"

"What pattern is there?"

Formulate the Problem

Helpful Verbal Nursing Strategies

"In what way is this problematic?"

"What do you want to see changed?"

Validate the Formulation

Helpful Verbal Nursing Strategies

"Do you mean…?"

"Let me tell you what I understand you to be saying."

Use the Formulation to Identify Ways to Solve or Manage the Difficulty

Helpful Verbal Nursing Strategies

"What would you do the next time?"

"In what way has your view changed?"

"What actions are needed to solve the problem that you've identified?"

Try Out the Solutions, Judge the Outcomes, and Adjust the Plan Accordingly

Helpful Nursing Strategies

Encourage application in new situations through role playing or through practice in appropriate settings; help the individual cycle through the preceding sequence as needed to evaluate the outcome and make adjustments to the plan.

Source Peplau, H. E. (1963). Process and concept of learning. In S. Burd, & M. Marshall (Eds.), *Some clinical approaches to psychiatric nursing* (pp. 333-336). New York: Macmillan.

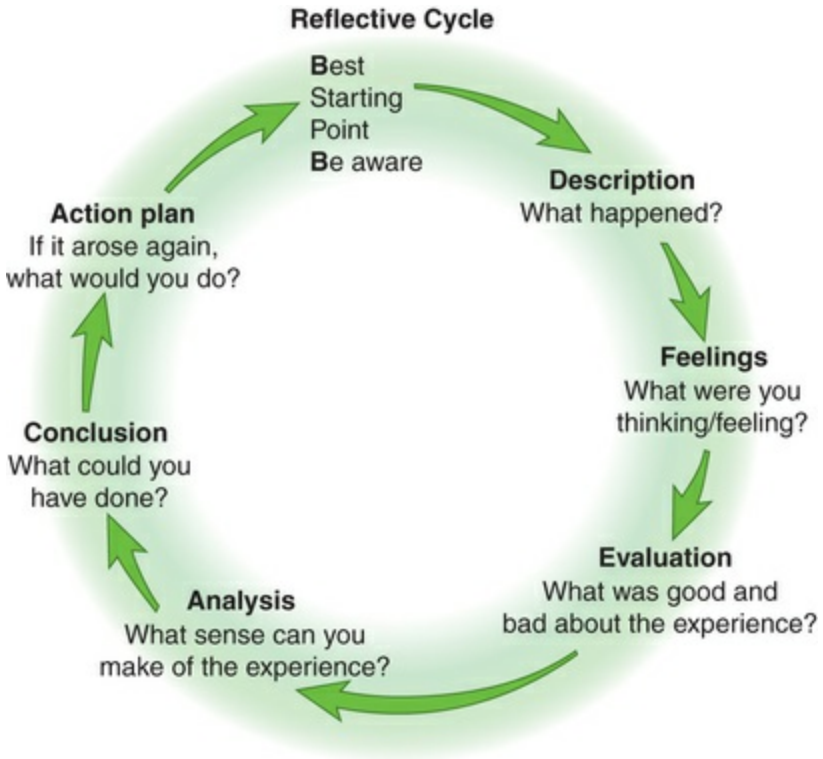

FIGURE 4-2 The process of reflection. The reflective process is illustrated here with entry at any point to examine events, associated thoughts and feelings, and analysis with a goal of understanding the events and one's reactions/actions as well as formulating a plan for responding effectively to similar events in the future.

Use Reflection

Reflection is the restatement of what the individual has said in the same or different words. This technique can involve paraphrasing or summarizing the person's main point to indicate interest and to focus the discussion. Effective use of this approach does not include frequent, parrot-like repetition of the individual's statements. Instead, reflection is the selective paraphrasing or literal repetition of the person's words to underscore the importance of what has been said, to summarize a main concern or theme, or to elicit elaborated information. In addition, to verify understanding of health information, the nurse can ask the person to restate what has been communicated. Failure to confirm understanding interferes with desired clinical care outcomes. For example, Bolster and Manias (2010) identified failures in communication, including lack of comprehension of information from providers, as a barrier to consumers' participation in their care.

Use Constructive Confrontation

Confronting an individual means that the nurse points out a specific behavior and then helps the person to examine the meaning or consequences of the behavior. For example:

Nurse: "You missed your appointment for the consultation we had scheduled."

Individual: "Oh, I didn't notice the date."

Nurse: "You are usually very aware of time and appointments. What do you think was going on with you that you didn't notice the date this time?"

This type of confrontation is not an angry exchange but a purposeful way of helping the person examine personal actions and their meaning.

Use Nouns and Pronouns Correctly

Some individuals have difficulty separating themselves from others or specifying the object or subject in their language. These individuals misuse pronouns by referring to we, us, they, she, he, him, and her, without clearly identifying the referent, and by making vague statements such as "They don't like me. They told me I was useless." Others may use general nouns, such as everyone, people, doctors, and nurses, to avoid clear communication about specific persons. The nurse can clarify the meaning by asking, "Who are they?" or "Who is the person?" Additionally, the nurse must be careful to use separate pronouns when speaking of herself or himself and the individual, particularly when the person has disordered thinking. For example, when communicating with an individual who is confused or exhibits disordered or psychotic thinking, the nurse should say "you" and "I," rather than "us" or "we," to promote clear thinking and communication and to assist the individual to maintain personal boundaries (Peplau, 1963).

Use Silence

Allowing a thoughtful silence at intervals helps the individual to talk at his or her own pace without pressure to perform for the nurse. Silence also permits time for reflection. Particularly helpful to the depressed or physically ill person, silence can reduce pressure and conserve energy. After several moments, the nurse can ask the person to share some thoughts. For example, "Try putting your thoughts into words," "Tell me what are you thinking or feeling now," or "I'll be here when you feel ready to talk."

Motivational Interviewing

Motivational interviewing (MI) is a person-centered communication approach used widely in health care and life coaching to assist individuals to make behavioral changes regarding a wide variety of lifestyle and health issues (Barrett & Chang, 2016; Ostland et al., 2015). Key components of MI are:

- Engaging—involving the individual in talking about issues, worries,

and desires, and to establish the basis for a trusting relationship.

- Focusing—narrowing the focus to habits or patterns that individuals wish to change.
- Evoking—eliciting motivation for change by increasing the sense of the importance of change, confidence, and readiness to change.
- Planning—developing practical steps that the individual wants to use to create the desired changes.

Nurses can seek training and use many available self-help and life coaching resources for health promotion (e.g., Hall, 2012). For example, *The Life Coach Workbook* (Raymond, 2014) is an example of a self-help book with useful tools that align nicely with MI that could be tailored to specific health care concerns. Such resources have high acceptability and can serve as helpful adjuncts to formal education and treatment/health-promotion guidance from nurses.

Current evidence supports the use of MI as an effective technique that can be taught to health professionals without advanced mental health training to promote desired behavioral change across health problems and settings. For training, use, and evaluation of MI implementation, nurses and other clinicians can use the Motivational Interviewing Skills in Health Care Encounters instrument, a reliable validated assessment tool to evaluate acquisition and use of specific MI skills and principles (Petrova et al., 2015).

Barriers to Effective Communication

Barriers to effective communication can originate with the nurse, the individual, or both. The most obvious barrier is the nurse's failure to use the types of therapeutic techniques just described. Lack of knowledge or experience can limit the nurse's ability to assess the individual's needs and repertoire of skills. Supervision and study can help the nurse apply the steps of the nursing process by using effective intervention approaches.

Communication is also ineffective when some part of the communication-feedback loop breaks down. Failure to send a clear message, receive and interpret the message correctly, or provide

useful feedback can interfere with communication. Diagnosing the source of the communication breakdown, taking steps to correct it, and using knowledge of the communication process and appropriate therapeutic techniques are the nurse's responsibility.

Anxiety

When the nurse or individual is highly anxious during an interaction, perception is altered and the ability to communicate effectively is curtailed sharply. Defense mechanisms, such as denial, projection, and displacement, reduce anxiety but block understanding of the true meaning of an interaction. Severe anxiety and defense mechanisms distort reality and lead to disordered communication. To enhance interpersonal communication, the nurse identifies the feeling of anxiety and its source and uses anxiety-reducing interventions.

Attitudes

Biases and stereotypes can limit the nurse's and the individual's ability to relate. When the difficulty is the individual's problem, the nurse can assist by examining those views that interfere with the person's relationships. When the problem is the nurse's, openness in the supervisory relationship to examine personal behavior is crucial. When the nurse fails to examine his or her attitudes toward the person, negativity may be communicated and perceptions of the interaction may be distorted.

Gaps Between the Nurse and the Individual

Related to attitudinal barriers, differences in gender, age, socioeconomic background, ethnicity, race, religion, or language can block functional communication between the nurse and the individual. These factors can cause differences in perception and block mutual understanding. Newly licensed nurses have attributed communication problems to differences in language proficiency among nurses, including English as a second language, as well as to

problems in understanding non–English-speaking individuals (Smith-Miller et al., 2010). To reduce such gaps, nurses can question unclear verbal or written communications, seek clarification or assistance from translators, and explore the ways in which perceptions may differ and meanings can be clarified (Box 4-13: Diversity Awareness and Chapter 2).

Box 4-13

Diversity Awareness

Multicultural Context of Communication

As health care providers, nurses might believe that they have expert knowledge about health promotion and the treatment of illness that will be beneficial to others. Therefore, it seems logical that nurses would select appropriate information to share with individuals to help them maintain health and manage illness or alterations in health status. However, consider the possible influences of cultural differences between the nurse and individual.

Much of the knowledge generated from nursing-related disciplines and the sciences is rooted in a Western perspective. Particularly in the United States, knowledge is developed and interpreted from the perspective of the dominant cultural group, a white, Anglo-Saxon, Christian point of view. When this perspective remains unexamined, alternative perspectives are ignored and invisible. Nurses who are members of the dominant cultural group may be well-intentioned, but ineffective, when they attempt to engage a person of a different cultural group in a relationship without questioning how culture influences interactions, interpretations of events and information, and beliefs and values concerning health and health care practices. Preconceived ideas about people based on some characteristic or group affiliation, such as racial or ethnic identity, religion, country of origin, gender, or sexual orientation, can interfere with nurses' abilities to relate to people as individuals. At the same time, a lack of knowledge of other cultural groups hampers nurses' understanding

of the individual's point of view.

Guidelines for recognizing the multicultural context of communication in therapeutic relationships include the following:

- Make ethnocultural assessment a critical component of every clinical evaluation.
- Allow other people to define themselves.
- Ask the person, and the family as appropriate, about cultural health care practices and traditions.
- Respect cultural practices and traditions while providing opportunity for the person to voice preferences and make choices.
- Respect the language of others and do not assume superiority in language.
- Collaborate with trained translators and health promoters (people with the same ethnic or racial background as the individuals).
- Create intercultural open dialogue based on security and mutual respect.
- Avoid use of racist, sexist, ageist, and other forms of denigrating language.
- Do not perpetuate stereotypes in communication.
- Adapt communication to the uniqueness of the individual.
- Reject humor that degrades members on the basis of gender, race, ethnicity, religion, sexual orientation, country of origin, and so forth.
- Respect the rights of others to have different practices and customs.
- Do not allow injustice to continue through silence.

- Present information clearly to all people to help them make informed choices.

- Do not judge values, traditions, and practices on the basis of their similarity to or difference from personal values, traditions, and practices, but judge them on the basis of whether they facilitate human potential.

The following are some issues for the nurse to consider:

- When the nurse works with a person from a different cultural background, what are common barriers to establishing a therapeutic relationship?

- In learning about different cultural groups, is there a risk of creating new stereotypes that interfere with the ability to treat people as unique individuals?

- If the nurse has little or no knowledge about a person's culture, how can the nurse provide meaningful nursing care?

- Are the two previous questions contradictory? How can the nurse meet the different challenges that they imply?

- Research measurements typically are developed from the perspective of the dominant culture. If the nurse wishes to use a standardized instrument to measure clinical or research variables among members of different cultural groups, then what questions about the instrument should the nurse ask, and what problems might the nurse encounter? What would need to be done to determine whether or not an instrument truly measures the same phenomenon across different populations?

- Consider the possible influences of cultural differences between the nurse and the individual. Think of an example of two people from diverse cultural groups who developed a relationship. Examine how they got to know each other and what differences and

similarities they uncovered. Did barriers to understanding each other exist? If so, how did they bridge these barriers? What did they learn about themselves? What did they learn about the ways that culture shapes perspective and interactions? Think about how a nurses can apply these insights to their relationships with people from cultural groups that differ from their own.

- How would a multicultural perspective change the practice?

Moreover, generation gaps between faculty and student nurses can interfere with effective development of the interpersonal skills required for therapeutic nurse-person relationships (Bhana, 2014). Generation Y students, born from the early 1980s to the late 1990s, constitute a large cohort of current undergraduate/pre-licensure and graduate nursing students. Evidence from the literature demonstrates that this generation benefits from deconstruction pedagogies or interactive teaching strategies such as debates, case studies, role playing, storytelling, journaling, simulations and webpage links to audio and video page links, rather than more traditional didactic approaches (Bhana, 2014). As younger generations (e.g., millennials), who have been raised with technology at their fingertips, enter nursing, teaching approaches will require ongoing change with use of more technology and interactive approaches. Nonetheless, our students also need to learn how to adapt their technology-mediated modes of communication to the styles and skills of older generation persons and those who may not have had the same access to technology when communicating with persons in the health care system and in professional situations. So although faculty members need to be adept at engaging students with a variety of effective strategies, students also need to be coached to use appropriate communication approaches across situations and populations. For example, evidence supports the effectiveness of video feedback, another technological teaching/learning strategy, to enhance the quality of communication, clinical competence, and MI skills of practicing nurses (Noordman et al., 2014). Thus ongoing faculty

development and testing of various teaching approaches to help students develop competence in therapeutic communication and relationships is crucial to nursing's future.

Resistance

Resistance comprises all phenomena that inhibit the flow of thoughts, feelings, and memories in an interpersonal encounter and behaviors that interfere with therapeutic goals. Resistance arises from anxiety when a person feels threatened. To reduce this anxiety, the person implements resistant behavior to divert the focus, most often in the form of avoidance, such as being late, changing the subject, forgetting, blocking, or becoming angry.

Initially, the nurse should identify the behavior, whether it is the nurse's or the individual's behavior, and then attempt to interpret it in the context of the interaction. Exploration of possible threats in the relationship, goals, context, or a particular topic can lead to understanding the source of the resistance and finding the ability to handle these difficulties. Anxiety reduction is often a necessary step in dealing with resistant behavior.

Transference and Countertransference or Distorting

Transference is reacting to another person in an exchange as though that person were someone from the past. Another term for this process is **distorting**. Transference, although a concept from the psychoanalytic/psychodynamic tradition in psychiatry and psychiatric nursing, retains relevance today. It is best understood as a process that distorts a current relationship or interaction on the basis of past learning, expectations, and/or relationships. Transference or distorting may involve a host of feelings that generally are classified as positive (love, affection, or regard) or negative (anger, dislike, or frustration). Typical transference reactions involve an important figure from the past such as a mother or father; however, at times transference may be more general to include all authority figures. Something about

another person's characteristics, behavior, or position, in combination with individual dynamics and context, triggers this response. People in a therapeutic relationship often develop strong transference feelings toward the helping professional, arising from the interaction's intensity and the care provider's authoritative or nurturing role. When transference or distorting reactions interfere with the current relationship (i.e., when reactions are out of proportion to the actual situation such as excessive anger in response to a nurse's suggestion), they require gentle probing by pointing out the reaction and asking about the associated thoughts and feelings, and possible past reactions in similar circumstances (e.g., responses to authority figures). To work with a person's transference reactions effectively, the nurse first helps the person to examine feelings and thoughts about the nurse with a nondefensive or reactive stance. Then the nurse assists the person to compare and contrast the nurse with people from the person's past to reduce distortions and comprehend the present reality to move forward effectively.

Countertransference is basically the same phenomenon and involves distorting, but it is experienced by the health care professional rather than the person. The nurse experiences many feelings toward the person; these feelings are not problematic, unless they remain unanalyzed and block the nurse's ability to work effectively with the individual. For example, if a nurse has strong feelings about the person and thinks that the person cannot possibly function after discharge without the nurse's aid, the nurse is likely to distort the person's abilities, encourage a childlike dependency, and interfere with the person's progress. This nurse needs to examine such personal feelings to understand their source. Once understood, countertransference reactions generally cease to interfere with the relationship. Consultation for supervision with an advanced practice psychiatric nurse or other mental health expert is recommended whenever transference or countertransference (i.e., distorting) reactions are persistent and problematic.

Sensory Barriers

When the individual has sensory limitations, the nurse may need to use extra skill in communicating. Use of the other senses to send or receive messages should be attempted. Special help is often available from trained therapists and teachers; for example, many agencies have access to interpreters for deaf people, and visual aids may be useful. Nurses must be as creative as possible, learn from others who are skilled in alternative forms of communication, and make referrals as necessary. As technology evolves, new communication methods will continue to decrease these barriers. For example, voice recognition software programs assist persons with visual and motor challenges to communicate via text.

Failure to Address Concerns or Needs

Failure to meet the individual's needs or to recognize the individual's concerns is the most serious barrier to effective interaction. This failure can arise from inadequate assessment, lack of knowledge, inability to separate the nurse's needs from the individual's needs, and confusion between friendship and a helping relationship, including unrecognized or unresolved sexual issues. To correct this problem, the nurse should recognize that a barrier to relating to the person exists. Using the supervisory process to determine the problem's source, the nurse should then take corrective action, such as obtaining more information or knowledge, performing a self-assessment with values clarification, and examining reactions, biases, and expectations. Nurses, particularly novice nurses and those transitioning to a new role (e.g., from staff nurse to nurse practitioner after graduate school), need to *demand* mentorship/clinical supervision that is not tied to performance evaluation. In other words, a supportive mentoring/supervisory relationship with a more senior nurse is a necessary ingredient in helping nurses to be effective. Cost-cutting efforts in today's health care system often neglect such needs. Yet consider the cost of a failed hire or ineffective relationships with care recipients. An argument for having professional support can be strong. Additionally, nurses can create their own cost-effective professional support systems by creating peer groups and/or

engaging their own consultants with a peer group outside the work setting.

Setting

The setting of a therapeutic interaction can affect the goals and the nature of the communication. The most important aspect of any setting is that the nurse and the individual are able to attend to each other. The nurse's attention to the person helps create this atmosphere. The nurse assesses the influence of factors such as lighting, noise, temperature, comfort, physical distance, and privacy; potentially disturbing factors can be altered or controlled within the limits of the setting. Occasionally the nurse has only minimal control over the setting, as in a busy clinic, health center, inpatient unit, emergency department, or the individual's home. Although far from the ideal of a quiet, pleasant, well-lit private office, these typical clinical settings can be used effectively by creating a sense of private space. Curtains can be drawn, doors shut, and two chairs pulled to a corner to shape an environment for interaction. When possible, however, nurses seek offices or rooms to establish privacy during significant communication or when imparting important or complex health information. Home settings can also be more comfortable for individuals than for nurses, yet also can provide invaluable context when used. The nurse can also acknowledge verbally that some aspect of the environment, such as an interruption or noise, is bothersome. This strategy shows people that the nurse recognizes possible concentration difficulties and is sharing the environment with them.

Stages

Therapeutic relationships follow sequential phases, which may overlap, differ in length, or involve issues that appear over time rather than in a set sequence. Orientation (introductory), working, and termination phases have been identified by researchers and clinicians (Canabrava, 2011; Stuart, 2012).

Originally these **relationship stages** were identified from clinical

interactions that developed over a prolonged period. However, they can be observed in brief encounters that are effective; that is, interactions that meet individuals' needs rather than therapeutic interactions that have been reduced to little more than quick question-and-answer sessions. Whether the nurse is engaged in a long-term or short-term relationship with an individual, attention to the relationship stages is important. Brief therapeutic relationships will telescope the stages; therefore it is particularly important that the nurse focus on meeting the key demands of each relationship phase. It is important to note that individuals may move in and out of direct care episodes, while a therapeutic relationship can be maintained over a longer period. A relationship exists even when the nurse and the individual do not see each other for an extended period, and each encounter occurs within the trajectory of the relationship stages.

Orientation or Introductory Phase

The orientation or introductory phase begins when the nurse and the individual meet. This meeting typically involves some feeling of anxiety; neither party knows what to expect. When the therapeutic relationship is primarily a counseling type of relationship, part of the nurse's role is to help structure the interaction by discussing several topics during the initial meeting and sometimes during the first few meetings. Box 4-14 lists topics appropriate to this phase. Discussion of these issues establishes a contract or pact and involves a mutual understanding of the parameters of the relationship and an agreement to work together.

Box 4-14

Key Topics of Discussion During the Orientation or Introductory Phase of the Therapeutic Relationship

- What to call each other

- Purpose of meeting
- Location, time, and length of meetings
- Termination date or time for review of progress through follow-up
- Confidentiality (with whom clinical data will be shared)
- Any other limits related to the particular setting

The orientation stage is a critical juncture in any therapeutic relationship. Without successful transition through the orientation phase, no working alliance will exist and the treatment goals will remain unmet. Consistency, sensitive pacing of communication, active listening, conveying concern and warmth, and paying attention to comfort and control help to establish a connection during the orientation phase. In contrast, inconsistency, unavailability, individual factors associated with trust, nurses' feelings about the other person, confrontation of delusions or strongly held views, and unrealistic expectations hamper relationships.

When the therapeutic relationship is not structured primarily as counseling with a specific number of sessions, the orientation phase may appear less distinct and the topics noted may seem irrelevant. In this case, the nurse can adapt the suggested topics to meet the specific situation. However, except in true emergencies, initial encounters should always include introductions by name, discussion of the purpose, and presentation of a plan for ongoing care or specific follow-up.

Working Phase

The working phase of the therapeutic relationship emerges when the nurse and the individual collaborate as partners in promoting the person's health. The working phase may last for only a brief time to establish a treatment plan, may last for an established number of sessions, as in brief psychotherapy, or may extend over a longer

period if the nurse is the primary care provider, care manager, or long-term caregiver in any setting or context for an individual or family. During the working phase, the relationship is the context through which change occur. Goals are set, and the nurse and the individual work mutually toward their accomplishment. Interventions are tailored to the specific situation and health needs of the person and the family. Solving problems, coping with stressors, and gaining insight are all part of the working phase. The nurse and the individual recognize each other's uniqueness and establish trust as the first step in establishing a working relationship.

Resistant behaviors may be observed during this phase while the nurse and the individual become closer and work on potentially anxiety-producing problems. The person may pull away through the use of defense mechanisms because change can be difficult. Overcoming the resistance becomes an important nursing task.

Termination Phase

Termination marks the end of the relationship established in the therapeutic contract or negotiated in accordance with the limits of the contract. Ending a relationship can cause anxiety for both the individual and the nurse. Termination represents a loss; therefore it can trigger feelings of sadness, frustration, and anger. Termination in this case is the loss of a relationship and the loss of future involvement, with its attendant realistic expectations or fantasies. Termination also reawakens feelings of previously unresolved losses, such as a death or divorce.

Working through any feelings related to termination is an important part of clinical care. Some individuals require the nurse's assistance to experience the feelings of loss and to connect present reactions to past real or symbolic losses. Box 4-15 lists additional interventions for use during the termination phase.

Box 4-15

Interventions for Use During the

Termination Phase of the Therapeutic Relationship

- Let the person know why the relationship is to be terminated.
- Remind the person of the date and how many meetings or appointments are left.
- Collaborate with other staff so that they are aware of how the person is reacting and any special needs that the person may have.
- Help the person to identify sources of support and other people with whom a relationship is possible.
- Review the gains and the remaining goals.
- Discuss the pros and cons experienced during the relationship to help the person develop a realistic appraisal.
- Make referrals for follow-up care as needed.

Both the nurse and the individual can learn much during termination; the process directs both participants to examine problems and progress in the relationship, feelings, and reactions. The experience also helps the nurse and the individual gain practice in ending relationships and in exploring reactions, which can be most helpful when future losses occur. Nonetheless, major gains can be accomplished with the deadline of termination. Options for follow-up or future treatment as the need determines also require exploration and planning.

Brief Interactions

Time constraints in practice are unavoidable. Although challenging, brief therapeutic encounters can be meaningful and useful. Limited time is not a valid reason to avoid interviewing or interacting with

individuals. Rather, nurses purposefully can structure brief interactions to achieve specific clinical outcomes (Wright & Leahey, 2013). Box 4-16 delineates key ingredients for a **15-minute** (or shorter) **interview** with a family.

Box 4-16

Key Ingredients for a 15-Minute (or Shorter) Family Interview

- Use manners to engage or reengage family members. Make an introduction by offering your name and role. Orient family members to the purpose of a brief family interview.
- Assess significant areas of internal and external structure and function (obtain information from a genogram concerning basic family composition and external support data).
- Ask family members three key questions.
- Commend the family on one or two strengths.
- Evaluate usefulness and conclude.

Source Wright, L. M., & Leahey, M. (2013). *Nurses and families: A guide to family assessment and intervention* (6th ed.). Philadelphia: F.A. Davis.

These guidelines for brief interactions with families can be adapted for interviews with individuals. An effective 15-minute (or shorter) interview is feasible if nurses plan to introduce themselves, state the purpose of meeting, validate understanding with the person or the family, clarify parameters such as time, focus and listen, and elicit significant individual and family data. Most important, the goal of the interaction must be realistic and clearly defined. For example, the purpose may be to elicit a family's view of the problem for which the person has sought care or to prioritize problems to be treated. Even

when time is limited, the interview is structured to provide an opportunity for the person or the family to engage in dialogue as an active participant in care, and the nurse's attention is completely focused on the individual.

Circumstances also can dictate the need for immediate and instructive communications that command specific actions. For example, during a crisis, directive, clear communication is paramount. Miller and McCurley (2011) demonstrated the importance of preparedness and communication strategies during disaster-related events. Planning in anticipation of human-caused and natural disasters is critical so as to have functional communications systems in place. Such systems increasingly will use various methods of telecommunication. After tragic events have occurred, including shootings on college campuses, efforts to communicate more effectively are paramount. Universities, for example, have responded by instituting systems to communicate rapidly with a large campus community. Widely deployed strategies feature instant text messaging and e-mailing (see Box 4-6: Innovative Practice).

The following case study presents a detailed scenario of a home visit and questions related to how the nurse can develop a therapeutic relationship with the person. The care plan presents a plan of care for the person, including communication interventions.

Case Study

A Health-Promotion Visit: Maria Sanchez-Smith

As part of a health-promotion visit for Maria Sanchez-Smith and Thomas, her 2-week-old infant, Jessica Wong, a registered nurse, planned to conduct an infant assessment, provide breastfeeding support, teach about normal infant development and care activities, and assess Mrs. Sanchez-Smith's adaptation to motherhood and her postpartum recovery status. Before the visit, Ms. Wong reviewed the clinical information she obtained during Mrs. Sanchez-Smith's hospitalization. Mrs. Sanchez-Smith is a 34-year-old Hispanic

primiparous woman who delivered a 7-pound, 10-ounce healthy boy (Thomas) after a 12-hour labor. The labor had progressed well without complications. Mrs. Sanchez-Smith received epidural anesthesia at 6-cm dilatation, and the baby was delivered vaginally. Her husband, Mark Smith, provided labor support and was present for the delivery. After a 2-day hospital stay, Mrs. Sanchez-Smith was discharged. At discharge, the infant was breastfeeding, had normal newborn examination findings, and weighed 7 pounds, 5 ounces. Ms. Wong had been impressed by both parents' preparation for the birth. They had attended childbirth classes and read several books about infant development and parenting. Ms. Sanchez-Smith planned to take an 8-week maternity leave from her position as a lawyer in a large practice and had arranged for a child care provider to come to the family's home to take care of the infant beginning 2 weeks before the end of her maternity leave. Mr. Smith had not planned to take time off from his job because he had recently been promoted to a high-level managerial position in his company that required increased travel and time at work. He was able to postpone a business trip to be present at the delivery and had sent a plane ticket to his mother-in-law so she could come and stay at their home during the first week after Mrs. Sanchez-Smith and Thomas were discharged from the hospital.

During the visit, Ms. Wong first assessed the infant. She incorporated teaching concerning normal infant development and concluded that Thomas was a healthy 2-week-old infant who was feeding well. Thomas's circumcision was healing without complications and he had regained his birth weight.

When Ms. Wong asked how Ms. Sanchez-Smith was doing, Ms. Sanchez-Smith hesitated and then responded, “I'm not sure. I'm very glad that Thomas is doing well… but I worry sometimes that I'm not going to be able to do everything right for him. It's funny, but I've spent so many years getting an education and establishing my law career. It was hard work, but I managed to do well. Now a little infant overwhelms me. I don't know how I'll manage this.” When Ms. Wong asked Ms. Sanchez-Smith to talk more about her concerns, Ms.

Sanchez-Smith described how incompetent she felt while her mother was staying with her. “My mother could do everything so easily. I fumbled with every diaper. It felt like she criticized how I did things. When she told me about what she did when she had children, I felt pushed to do things ‘her way’ and not the way that I had planned. She even wanted to give him a bottle when I was trying so hard to get breastfeeding going. At least the doctor said Thomas had gained enough weight. Thomas' weight gain made me feel like I wasn't a total failure. I couldn't wait for her to go, but I fell apart after she left. I was alone. Mark is out of town until the weekend, and I couldn't get Thomas to stop crying yesterday. I thought I would scream, so I put him down in his crib and I just sat there crying. What's wrong with me? I've never felt so out of control before. I want to be a good mother, but I feel like I can't give any more right now.”

In response to Ms. Wong's follow-up questions about mental status, Mrs. Sanchez-Smith described frequently feeling irritated and sad, crying a few times over the previous several days, having difficulty sleeping even when the baby was asleep, feeling fatigued, and being worried about how she would be able to go back to work in only a few weeks. Ms. Wong also inquired about the family's cultural, ethnic, and religious backgrounds. Mrs. Sanchez-Smith responded, “Interesting that you should ask. That's actually another issue right now. I'm from New Mexico and my family is Hispanic and Catholic, but I'm not a practicing Catholic now. You might guess that I'm Latina from my hyphenated name. I added my maiden name to Smith when I got married to honor my family. Mark is Protestant, but not really religious. His family comes from New Jersey. They are very nice and were supportive when we got married. We were lucky that our families accepted us together. I have to admit, though, that we didn't really figure out what we would do about raising the baby. Mark thinks that we'd be hypocrites to have a Catholic christening. Plus, my mother told me that I'd be selfish to go back to work so soon. Can you help me? I feel like I'm going out of my mind and I don't know what to do.”

This case study raises a variety of clinical concerns. As the nurse in

this encounter, Ms. Wong could begin by considering the following questions.

Reflective Questions:

- What are my feelings as I listen to her story and her distress? Am I aware of how my values and expectations affect my interaction with this person? How can I establish a therapeutic relationship to support Ms. Sanchez-Smith during this stressful period?

- What is the significance of the distress symptoms that Ms. Sanchez-Smith reported? Given that the period during which many women experience postpartum blues has passed, what is the most appropriate action for referral to obtain a thorough mental status examination for postpartum depression?

- Who is the most appropriate health care provider to evaluate her for postpartum depression, and treat her if it is confirmed? How can I facilitate getting her the care she needs, and can I remain available to her? How can I assist Ms. Sanchez-Smith to meet the infant's developmental needs during this stressful period?

- In what ways do family dynamics, values, and expectations related to differing cultural and religious heritages contribute to the problems described? What can I do to explore these issues further? What strengths can be harnessed? Are there clergy who could be engaged for pastoral counseling? How can I engage support systems to ameliorate rather than exacerbate the difficulties? What can be done to engage both Mr. Smith and Ms. Sanchez-Smith in a therapeutic relationship to focus on the couple and parenting concerns, and to involve both partners in treatment strategies?

Care Plan

Transition to Parenthood: Maria Sanchez-Smith

***NURSING DIAGNOSIS: Risk of impaired parenting related to stress involved in transition to parenthood**

Defining Characteristics

- Feeling overwhelmed with responsibilities of new parenthood
- Insecurity about tasks of infant care
- Crying
- Sadness
- Feeling out of control
- Difficulty sleeping even when the baby is asleep
- Worry about going back to work soon

Related Factors

- Transition from high career achievement to new role as mother.
- Differing religious, ethnic, and cultural backgrounds of the two parents and extended families.
- Confusion and lack of decisions about religious and cultural traditions to follow for their infant.
- Conflicting expectations of extended families, particularly from Ms. Sanchez-Smith's mother.
- Job pressures on Mr. Smith to travel and be away from home.
- Unanticipated social isolation for Ms. Sanchez-Smith during this postpartum period.
- Limited social support (particularly from the husband because of

work-associated travel).

Expected Outcomes

- Competent mothering and infant care are displayed.
- Ms. Sanchez-Smith describes her feelings, concerns, and needs.
- Indicators of postpartum depression are evaluated, and referral for follow-up is made for positive findings.
- Social supports are engaged.
- Ms. Sanchez-Smith and Mr. Smith successfully negotiate immediate decisions about religious and cultural practice concerning their baby and agree to use counseling services to work out decisions concerning their child's upbringing and involvement of the extended family.

Interventions

- Health information is provided about normal newborn and postpartum adjustment.
- Infant care information is provided on the basis of Ms. Sanchez-Smith's needs.
- Expectations about postpartum adjustment and parenthood are elicited.
- Health information about postpartum depression is provided regarding prevalence and common symptoms.
- Personal and family histories are obtained, with a focus on mental health.
- Postpartum depression is evaluated with use of interview questions

and an assessment measure, such as the Edinburgh Postnatal Depression Scale (Cox et al., 1987) or the Postpartum Depression Screening Scale (Beck & Gable, 2001).

- If symptom levels suggest postpartum depression, a referral for mental health evaluation is made. If there are any signs of safety risk to self or others, immediate protective action (e.g., emergency mental health evaluation) is taken.
- Sources of social support are solicited, and specific plans are made to use available support, such as the husband, friends, and hired infant care providers.
- Conflicts and areas of shared values, plans, goals for raising the baby are explored.
- Pros and cons of options for raising the baby are examined in relation to religious, ethnic, and cultural considerations.
- A follow-up plan is made to reassess symptoms of postpartum depression and to discuss ongoing concerns about how to raise the baby with Mrs. Sanchez-Smith and Mr. Smith.
- Referral is made to local support and psychoeducational programs for interfaith couples.

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses - Definitions and Classification 2015-2017. Copyright © 2014, 1994-2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Relating to persons has many challenges and rewards for nurses. Although some aspects of this work are predictable, each person and family is unique and provides a chance for the nurse to learn, grow, and help in new ways. This chapter has provided guidelines for developing therapeutic relationships, but these guidelines do not guarantee success or an easy job. The desire and skill of the individual nurse bring this information to life. The blend of the nurse's artistry, humanity, knowledge, skill, and ethics sparks concern and the ability to help another human being communicate effectively; essential components of the nurse-person relationship.

The therapeutic relationship is the primary arena for health promotion. Values clarification, communication, and the helping relationship are its core components. For nurses, applying this knowledge to their varied roles is essential to promoting health and providing quality care.

Rising use of technology and mounting pressures for cost-effective care are here to stay. In this climate, the importance of the therapeutic relationship is underscored (see Box 4-6: Innovative Practice). Without a relational context, the care dimension in health care is lost, and health promotion is reduced to standardized, recipe-like prescriptions. Effective health promotion directed to the needs of individuals, families, and communities requires reflection on the value of caring, effective communication, and a helping relationship.

Ethical Issues Related to Health Promotion

Christine Sorrell Dinkins

OBJECTIVES

After completing this chapter, the reader will be able to:

- Discuss health promotion as a moral endeavor.
- Describe the relationship of health care ethics to health promotion.
- Analyze the relationship of various ethical theories to the nursing role in health promotion.
- Discuss the historical development and importance to nursing of the codes of ethics.
- Describe contemporary ethical issues in health promotion (e.g., issues related to genetics, genomics, culture, end-of-life decision-making).
- Analyze problems related to health promotion using an ethical decision-making framework.

Think About It

Assisted Suicide or Emotional Support?

A nurse in a clinic is accountable for ongoing assessments of pain management. One of the long-term clients, Ana, has required increasing amounts of narcotics for her pain management over the last year. The nurse has known for more than a year that Ana's husband, Victor, has amyotrophic lateral sclerosis, or Lou Gehrig disease. Victor's disease adds a great deal of stress to both their lives, which has had a negative effect on Ana's physical health. The nurse assesses the emotional toll of Victor's illness as part of Ana's pain assessment. During one of these discussions, Ana asks the nurse how much of her narcotic medication her husband would need to take to end his life.

- What are the implications of providing someone, indirectly, with the means to commit suicide?
- What questions would you have for Ana at this point of the conversation?
- Imagine how she might respond. What would you say or do in response to her answers?
- Do you have any obligations to Victor?

- Do you think you should collaborate with Victor's physician?
- What is in Ana's best interests?
- Who or what are your resources?
- Do national nursing organizations have written guidelines about assisted suicide?
- What is the law in your state?
- What should you do?

Health Promotion as a Moral Endeavor

The American Nurses Association (ANA) designated the year 2015 as "The Year of Ethics." A highlight of the year was a revision of the *Code of Ethics for Nurses with Interpretive Statements*, which was the first revision since 2001. The revised code provides a succinct statement of ethical values, obligations, and duties of nurses and describes nursing's understanding of its commitment to society. The code frames how nurses provide service to society through health-promotion interventions; this care can be seen as a moral endeavor. Nurses confront moral issues in the process of attempting to enhance the well-being of a society overall, as well as promoting and protecting health for individual members of a society. Health is considered a human good because it helps people to have a desirable quality of life and achieve life goals. At the level of the individual, health promotion involves providing services that help people achieve their potential.

To set a higher standard of health for all people, it is important to understand the contexts of people's lives. This understanding entails consideration of a variety of factors that can affect a person's health status, such as mental, physical, spiritual, environmental, cultural, social, and genetic factors. Viewing health promotion as a moral endeavor is consistent with the intent and goals of the US government's prevention agenda for the nation as presented in *Healthy People 2020* (see https://www.healthypeople.gov).

The following are the four overarching goals of *Healthy People 2020*:

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors

across all life stages.

The purpose of health-promotion efforts, as discussed throughout this book, is to ensure that people have access to the tools and strategies to live at the highest level of well-being possible. Health-promotion efforts address environmental obstacles to human health, such as pollution, marketing of harmful products, and economic disparities. Thus health promotion is not the province of a single discipline but requires collaboration of patients, health care providers, and institutions working together to create a nurturing environment for achieving health goals.

This chapter focuses on understanding the health professional's moral responsibilities toward individuals and society with regard to facilitating health and well-being, or the relief of suffering. Professional responsibilities are obligations incurred by disciplines that provide a service to society. For example, the *Code of Ethics for Nurses with Interpretive Statements* (ANA, 2015) states that nursing addresses the "protection, promotion, and restoration of health and well-being; the prevention of illness and injury; and the alleviation of suffering, in the care of individuals, families, groups, communities, and populations." This document, along with the ANA's "Nursing's Social Policy Statement" (ANA, 2010), describes the ethical responsibilities of US nurses (Boxes 5-1 and 5-2). The weblinks for this chapter include a link to the ANA's *Code of Ethics for Nurses with Interpretive Statements*. The International Council of Nurses (2012) also has a code of ethics, revised in 2012, which serves as a standard for nurses worldwide and is easily accessible via the Internet.

Box 5-1

Code of Ethics for Nurses

- The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every person.
- The nurse's primary commitment is to the patient, whether an individual, family, group, community, or population.

- The nurse promotes, advocates, and protects the rights, health, and safety of the patient.
- The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and to provide optimal care.
- The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.
- The nurse, through individual and collective effort, establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality health care.
- The nurse, in all roles and settings, advances the profession through research and scholarly inquiry, professional standards development, and the generation of both nursing and health policy.
- The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.
- The profession of nursing, collectively through its professional organizations, must articulate nursing values, maintain the integrity of the profession, and integrate principles of social justice into nursing and health policy.

Box 5-2

Nursing's Social Policy Statement

Excerpt: Knowledge Base for Nursing Practice

The knowledge base for nursing practice includes nursing science, philosophy, and ethics.

Nurses partner with individuals, families, communities, and populations to address such issues as:

- Promotion of health and safety
- Care and self-care processes
- Physical, emotional, and spiritual comfort, discomfort, and pain
- Adaptation to physiological and pathophysiological processes
- Emotions related to experiences of birth, growth and development, health, illness, disease, and death
- Meanings ascribed to health and illness
- Decision-making and ability to make choices
- Relationships, role performance, and change processes within relationships
- Social policies and their effects on the health of individuals, families, and communities
- Health care systems and their relationships with access to and quality of health care
- The environment and the prevention of disease

Source American Nurses Association. (2010). *Nursing's social policy statement. The essence of the profession* (3rd ed.). Silver Spring, MD: American Nurses Association.

Ethical issues focused on health promotion are best viewed as a subset of health care ethics that, in turn, has its roots in moral

philosophy and value theory. This chapter discusses factors that can affect health promotion across the life span in diverse health care settings. The development, scope, and limits of ethical theories and perspectives are explored in relation to problems in health promotion. A basic assumption in this chapter is that the anticipation and prevention of ethical problems is a critical component of ethical professional action. A variety of real and hypothetical cases are presented to illustrate how ethical issues relate to health promotion. Strategies to aid nurses in identifying, anticipating, and addressing ethical issues are provided throughout.

The terms *ethical* and *moral* are used interchangeably throughout the chapter. Even though the two concepts are sometimes characterized differently, they have the same root meanings. The term *ethics* is derived from the Greek word *ethos*, meaning customs, conduct, or character. The term ***moral*** is derived from the Latin word *mores* and originally referred to doing something from a custom or habit (Sproul, 2015).

Health Care Ethics

Origins of Applied Ethics in Moral Philosophy

The discipline underlying ethical practice, or **applied ethics,** is moral philosophy. **Moral philosophy** is concerned with discovering or proposing what is right or wrong, or good or bad, in human action toward other humans and other entities such as animals and the environment. Singer (1993) described the crucial questions of moral philosophy as "What ought I to do? How ought I to live?" Among the tasks of moral philosophy is that of formulating theories or frameworks to guide action. Using a moral theory to propose and implement appropriate actions in troubling situations guides the decision maker toward good actions and the avoidance of harmful actions.

The theories that emerge as a result of philosophical inquiry about good action are called **value theories**; they are concerned with either discovering what humans seem to value (descriptive theories) or proposing what they ought to value (normative theories) to achieve predetermined goals. Value theories are based on observations of human behavior over time and in a variety of settings. **Descriptive theories** do not tell us what actions we ought to take. They are not directives; they merely tell us how people act toward each other and their environments and what they seem to believe are good or moral actions. **Normative theories,** in contrast, are concerned with ensuring good actions.

Types of Normative Ethical Theories

Normative ethical theories are reasoned explanations of the moral purpose of human interactions, or they are believed to be objective truths about good action (divinely given in the case of religious ethics). Actions that are in accord with the foundational principles of the theory are the type of right or good actions we should take given that we believe the principles (e.g., fairness and trust) are valid. What

is often called the golden rule is a classic example of a normative principle. The golden rule commits us to treating other people in the manner that we would wish to be treated, given similar circumstances. Normative theories permit judgments about the value of actions on the basis of the extent to which these actions are consistent with the assumptions of the theory. They are key to decision-making and relevant for health promotion but may be overlooked by policymakers.

Consequentialist Theories

The foundational principle of John Stuart Mill's (2002/1861) theory of utilitarianism proposes that actions are good insofar as they aim at yielding the greatest amount of happiness or pleasure or causing the least amount of harm or pain to individuals and overall society. This theory is often formulated as the greatest good for the greatest number. Mill viewed pleasure as a complex concept, with qualitative as well as quantitative aspects. This perspective is **consequentialist:** it holds that the consequences or intended consequences of actions matter for determining moral worth. Therefore from the consequentialist perspective, any decision about intended actions or interventions must take into account all knowable potential consequences. Among the implications of this type of theory for nurses is the imperative that data gathering must be thorough and complete. Additionally, the professional is accountable for possessing the appropriate skills and knowledge to undertake actions that will promote good. The professional's decision can be evaluated as bad or good to the extent that actions are in accord with the theory: in the case of utilitarianism, “right actions” would be those that are directed toward promoting the greatest good or causing the least harm. The propositions of the theory direct what is needed for moral action or, stated another way, for doing the right thing.

Duty-Based Theories

Other normative value theories are not as heavily weighted toward

producing good consequences. For example, **duty-based theories,** such as the theory of Immanuel Kant (1724–1804) and those of various religions (Judaism, Christianity, Islam), depend more on adherence to duties than on good consequences. Individuals are viewed as having certain duties that cannot be circumvented, even if deliberately avoiding the duty would result in good outcomes. For religions, these rules are imparted in some way by a divine being.

For Kant, our capacity to reason is what guides moral action. Moral reasoning has been proposed as a model for health promotion (Buchanan, 2006). Kant based his theory on the idea that what separates us from other life forms is our ability to make rules for ourselves using reason. His main rule, whereby each of us can determine for ourselves a moral course of action, is the categorical imperative. It is called the categorical imperative because it applies in all situations (categorical) and is a binding command (imperative). The categorical imperative was framed in several different ways by Kant. One major formulation is as follows: "Act only according to that maxim whereby you can at the same time will that it should become a universal law" (Kant, 1993/1785).

Kant's theory is easier to understand through examples. Kant argued that making a false promise is always wrong even if on some occasions it might produce a good outcome. It is wrong because it is irrational and the promise breaker is making a moral exception for himself or herself. If everyone made a false promise when the immediate outcomes were likely to be positive, humans would lose their ability to trust promises, and this would make promises pointless and ineffective. Thus making a false promise is irrational (and therefore unethical) because one is making a promise while counting on everyone else to act differently so that promises do not cease to exist. This formulation could thus be stated alternatively as a question to ask oneself before acting: "If I do this act, am I making a moral exception for myself? Am I counting on others to act differently than I am right now?" If a person asked this question before sneaking onto a bus without paying the fare, the answer would be "yes I am making a moral exception for myself (and therefore should not do

this),” because if everyone rode without paying the fare, the bus service could not run anymore!

Another formulation of Kant's categorical imperative is “Act in such a way that you treat humanity, whether in your own person or in the person of another, always at the same time as an end and never simply as a means” (Kant, 1993/1785). Kant calls us all to recognize every human being as a full human being with his or her own ends (i.e., life and goals). To treat someone merely as a means would be to use or ignore that person for one's own purposes. For example, it would be wrong to pretend to be friends with someone just so that person could help us study for a test. The various formulations of the categorical imperative will always lead to the same decision, so when we are deciding on an action, we can choose whichever formulation is easier (or more relevant) to apply in the situation.

Character-Based Theories

Also referred to as **virtue ethics**, character-based approaches to ethics center on the individual agent making the decision. Aristotle (384–322 BCE) argued that being moral was a matter of habits and desires. If a person can learn to desire the right things, then he or she will do the right things. For Aristotle (1985/350 BCE), doing the right thing is all about who you are. If you are a moral person with good ethical thinking skills, you will do the right thing. So, in any given situation, I might ask myself, “What would a good person do in this situation?” or “If I do this, will I be the kind of person I would consider to be a good person?”

Aristotle says that habits help us be moral in two ways: First, they help us put our desires in order. By always acting honestly, for instance, one will begin to form a desire for honest acts, so the habit of acting honestly makes one develop a desire to be honest. Second, habits help us learn how to be moral. The more one acts courageously, for instance, the better one become at it. By forming a habit of acting courageous, one is more likely to be able to know what the courageous thing to do is in any given situation, and will be more able to make oneself do it.

The advantage of Aristotle's character ethics is that instead of hard and fast rules to follow, he offers general advice, and thus his ethics is easily applicable to all situations. The drawback comes from the same source though: without any hard and fast rules to follow, it can be hard to look to virtue ethics to determine the right thing to do. Habits can help us learn, in general, how to be courageous, honest, temperate, kind, etc. Also necessary, though, is **practical wisdom** (*phronesis* in the original Greek). Aristotle's writings on ethics do not try to tell us what the right thing to do is in any situation. Instead, he describes the skills needed to figure out what to do in any situation. He takes this approach because he believes there is no one right way to act at all times. Any moral decision depends on the situation and the person making the decision.

Limitations of Moral Theory

Keep in mind that moral theories arise out of a particular perspective or philosophy about the world. They are conceptualized as a result of this perspective and within a historical and political context. The philosophical approach that evaluates value theories or ethical perspectives for their congruence and usefulness in human decision-making across environments is **metaethics.** Philosophers interested in metaethical questions investigate where our ethical principles come from and what they mean. Are they merely social inventions? Do they involve more than expressions of our individual emotions? Metaethics allows us to critique the adequacy of ethical approaches for application across a variety of practice settings and cultural environments. Other sorts of metaethical questions posed by moral philosophers include the following: Are there such things as absolute ethical truths? If so, how do we go about discovering these? If not, what foundations should we use to guide our actions? What is a valid moral theory? Should human values be congruent across settings and cultures?

Religiously based moral theories depend on the idea that good actions are those that obey the laws of a supreme being. However, because the foundational tenets of religions do not consistently mirror

each other, what constitutes a moral or morally neutral action from a Jewish perspective may well be morally prohibited from a Roman Catholic perspective. Moreover, even within a religion, the tenets of its different sects or branches may not always lead to the same conclusions about good actions. Nurses and other health care professionals need to recognize the influence of religion in persons' lives because their duty to provide safe, competent, compassionate, and ethical care extends to an accommodation of religious and cultural values and practices.

As a result of diverse religious and cultural values, there are divergent but strongly held views on what is the good for humans. Many contemporary philosophers have argued that there can be no single approach that permits the identification or resolution of all moral problems (Rachels & Rachels, 2011; Weston, 2010). Even the golden rule can be problematic from a cross-cultural perspective. For example, I might want to be treated as an autonomous being capable of making my own decisions, but a person from Thailand might be more used to family-centered decision-making. Treating my Thai friend as I would wish to be treated would be a mistake. An understanding of cultural beliefs is necessary for good action in such cases (Box 5-3: Diversity Awareness). Health care professionals wishing to engage in ethics respectful of diversity may be well served by "listening to the stories of those who are different, who may be unseen, marginalized, and excluded in our healthcare systems" (Sorrell & Dinkins, 2006). If we fail to listen to these stories, we are likely to be oblivious to the harm being done in health care through unwitting oppression of minorities or people from other cultures.

Box 5-3

Diversity Awareness

Self-Reflection

The increasingly multicultural society, multiple languages spoken, and diverse set of values presents health care providers with complex

assessment and planning problems. Nurses and other health professionals are charged with practicing "with compassion and respect for the inherent dignity, worth, and unique attributes of every person" (ANA, 2015, Provision 1). It is not possible to know details about every culture as well as the unique differences of each individual, family community, and group within each culture. There are strategies, however, that a health professional can use to ensure that an individual's unique values and particular needs are the focus of health-promotion interventions.

When a particular culture is part of your population base, opportunities should be pursued for learning individual differences in beliefs, values, and needs related to that culture. To facilitate your assessment, perhaps the most important undertaking is self-reflection. The following are self-reflection and other considerations for providing culturally sensitive care:

- Commitment to increasing knowledge and skill in sensitivity to cultural differences.
- Self-awareness and awareness of one's own biases, beliefs, and values. Ask yourself:
- what values and biases you bring to the relationship
- how your background has influenced your beliefs
- what knowledge and experience you have to draw on
- what values you think you share with the client (validate with the client)
- how comfortable you are with who you are

- what further information you need to facilitate culturally competent care
- who or what is the best resource for further information
- Awareness of the validity of different beliefs and values.
- Attempts to understand the meaning behind client behavior.
- Increased knowledge of the beliefs and values of other cultures.
- Developing cultural skills through encounters with people from other cultures.

Source American Nurses Association. (2015). *Code of ethics for nurses with interpretive statements.* Washington, DC: American Nurses Association.

Additionally, **utilitarian theories** emerged out of a particular era and as a result of perceived injustices in societal arrangements in England during the turmoil of the industrial revolution. Utilitarians such as Jeremy Bentham (1748–1832) and John Stuart Mill (1806–1873) sought frameworks that would permit the rectification of unjust policy decisions and the vast economic inequities within their society. For this reason, such theories have a tendency to privilege the good of the group over the needs of individuals. In health promotion, seeking a balance between good for the group or community and good for the individual can be a particular challenge. Utilitarian theories, in particular, are in danger of favoring the group (the majority) over those who are in fewer numbers (the minority).

The most famous illustration of how our ethical decision-making might be determined by our culture and context comes from Plato (~427 to ~347 BCE). In Plato's *Republic* (1992/360 BCE), the character of Socrates describes a cave where prisoners have been shackled since birth, and thus the cave is the only reality they know. The prisoners

face a cave wall on which they see shadows cast by the fire behind them, but they cannot turn their heads to see the fire and do not even know it is there. When one prisoner is freed, he journeys upward, first seeing the fire and eventually making it out into the wider world, lit by the light of the sun. Socrates says this prisoner's journey is the moral journey each of us must take. We must recognize that the morals we are taught may just be shadows of the true moral good (represented by the sun in the story).

Health practitioners today should be aware that they are likely most familiar and comfortable with the ideals and morals they have been raised with, and it is not always good to be limited by this perspective. As our society becomes increasingly complex, there are new and emergent ethical issues, such as protection of the environment, use of technology, allocation of scarce resources, and health care reform. Normative ethical theories give each of us means to think for ourselves and reflect on what we believe is right. It is not prudent to adopt one theory to guide actions in every situation related to health promotion. If a moral theory is applied unreflectively, it can lead to actions that are problematic for an individual or group. Health-promotion activities mandate not only a general understanding of the nature of the problem or potential problem but also knowledge of the values, beliefs, needs, and desires of the person or population being served. In addition, it is advisable that individuals look for an action or decision supported by more than one ethical theory—such confluence means that the action or decision will be morally right from multiple perspectives or contexts.

Specific principles derived from ethical theories have proved useful because they highlight salient aspects of complex problems and help to examine implications of different proposed courses of action. Selection of pertinent principles, however, depends both on the context of the problem and on the beliefs and values of the individual or group for which action is needed. For example, imagine a woman who seeks assistance in deciding whether to undergo genetic testing for the breast cancer gene *BRCA2* because several members of her immediate and antecedent families have received diagnoses of breast

or associated cancers. She tells her nurse practitioner that she is not sure whether it would be beneficial to be tested. The nurse practitioner, in facilitating the woman's health-promotion efforts, understands that she must use clinical judgment to facilitate the woman's autonomous choice. Understanding the requirements of the principle of autonomy is important in helping the woman make her decision. It is not sufficient, however, to understand the meaning of autonomy and its limits; the nurse practitioner must also know something about the woman's life, values, beliefs, and relationships to provide her with the information and resources necessary for her decision. If the woman is screened and the results are positive for the gene, the woman not only must decide her next actions but also must consider the implications of the results (e.g., how the results affect her children or her decision to have children). Box 5-4: Genomics presents information on **genetic counseling.** Individual principles of importance to decision-making in health care settings are explored in this chapter. They, along with associated ethical considerations such as professional, feminist, and virtue ethics, underpin a framework of moral decision-making for health promotion that is presented at the end of this chapter.

Box 5-4

Genomics

Nurses as Genetic Educators, Researchers, and Counselors

Nurses have always been important advocates for health care literacy and education. Since the International Human Genome Sequencing Consortium completed the Human Genome Project in 2003, nurses have stepped forward to gain new competencies and assume new roles related to genetics and genomics. In assuming these roles, nurses face ethical, legal, and social implications with patients and community members. These ethical, legal, and social implications

require a basic genomic health literacy, as well as an understanding of the expectations of the public. Research strongly suggests that people want to have their genetic sequencing results to better understand their health profile.

The rapidly increasing discoveries in genetic research challenge nurses to gain new competencies so as to be knowledgeable about the often difficult ethical situations related to these discoveries. **Genetics** involves the study of a single gene's function. **Genomics** represents a wider view to include all genes in a person, including interactions of the genes with themselves and also the environment (Huddleston, 2013; Lyon et al., 2011). Two other terms sound similar but have different meanings. **Genotype** refers to a set of genes in our DNA that is responsible for a particular trait. **Phenotype** is the physical expression of that trait, and is determined by interaction between the genotype and the environment. Genotype is an inherited trait; the entire genetic information about an organism is contained in a genotype. Examples of genotype are the genes responsible for eye and hair color and the sound of one's voice. Phenotype is what you see; it is the visible expression of the results of the genes combined with the environmental influence on one's appearance or behavior. Examples of phenotypes are the *visible* or *observable* characteristic of eye and hair color and the sound of one's voice.

These terms help nurses to understand how the integration of genomic and genetic factors into areas such as biobehavioral research provides new opportunities to understand problems that are difficult to define. For example, Lyon and colleagues (2011) noted that attempts to study fatigue have "been stymied by the lack of phenotypic clarity." These nurse researchers have studied genetic-genomic approaches that may increase the precision and clarity of the study of fatigue, thus enhancing understanding of mechanisms by which fatigue occurs in various health conditions as a patient symptom. Nurses are making important contributions through integration of genetic-genomic measures into biobehavioral research. This research may lead to better prediction of risk for medical problems, as well as identification of biological markers of symptom

onset, progression, and resolution. More research is also needed in examining the relationship between individual genetic/genomic variations and outcomes of nursing interventions so that nurses can use genetic/genomic information to plan nursing interventions. There are potentially many nursing interventions that would be more effective if they were individually tailored to a person's genetic/genomic profile, rather than a "one size fits all" approach (Munro, 2015).

The ever-expanding discoveries in genomics challenge the nurse to be competent in genomic applications to nursing care and knowledgeable in the often difficult ethical issues that arise with these discoveries. There is a need for nurses to position themselves so as to attain advanced knowledge and skills related to their serving as specialized genetic counselors. For example, behavioral phenotypes have emerged as an area of specialist practice for nurses in the field of intellectual disability (Higgins & Duffy, 2006). Although many health care professionals have the skills to counsel individuals about genetic testing issues, especially in their fields of expertise, genetic counselors are an increasingly important resource and are aware of ethical issues to consider in genetic screening.

Genetic counselors are specially trained master's-prepared individuals. These professionals can obtain certification through the American Board of Genetic Counselors. Their professional society is the National Society of Genetic Counselors. Genetic counselors enter the field from a range of backgrounds including biology, genetics, nursing, psychology, public health, and social work.

The goals of the discipline are outlined in the society's *Code of Ethics* (National Society of Genetic Counselors, 2006). Genetic counselors provide counseling services that are nondirective to avoid coercion or persuasion. Although there is controversy about how directive or nondirective advice should be based on the ethical ideals of autonomy, counselors strive to be nondirective while at the same time tailoring information to fit the specific needs of persons. Because advances in embryo preimplantation genetic testing, as well as in utero fetal testing, permit screening of individuals for certain superior

characteristics or the screening out of certain genetic diseases, the perceived need to distance the profession from this issue is understandable.

Ethical issues related to genetic counseling for screening purposes that apply both for genetic counselors and for other health care providers include the following:

- Understanding the wider context of genetic testing implications (privacy, discrimination, economics, health insurance denials, implications for family members, anxiety and apprehension, and eugenics [striving for perfection] and its associated implications for individuals and society).
- Assisting people to determine the risks and benefits of screening.
- Assisting people to prepare for their future needs.
- Assisting people with their procreative planning.
- Understanding how cultural differences impact counseling needs.
- Addressing societal issues related to genetic advances, including determining research priorities, justice issues, and discrimination of the genetically disadvantaged.

Feminist Ethics and Caring

Feminist Ethics

Feminist perspectives on ethics derive from the feminist movement's efforts to expose and rectify injustices to women and raise awareness of the dominance of patriarchy in many ethical approaches. The feminist movement perspectives also often include problems common to all oppressed groups. **Feminist ethics,** emerging as it has out of feminist thought and feminist philosophy, is not another ethical theory as such; rather it presents a viewpoint on moral problems in health care and other areas of life that have been historically neglected.

Feminist scholars have noted that traditional moral theories, and the principles derived from them, have been unable to adequately capture the nature and origins of health care problems. Feminist critics assert that moral decision-making must include an investigation of both hidden and overt power relationships implicit in ethical problems. Additionally, understand the contexts of situations and the interrelationships of those involved because human beings are not isolated individuals who may be viewed as totally independent of others. Thus hidden power imbalances in various relationships and situations are an important element in moral decision-making. Feminist ethics, then, contributes a perspective that is often missing from traditional ethical approaches and aims to change the way ethical problems are perceived and explored.

The characteristics of feminist ethics include (Green, 2012):

- An understanding that human beings are inseparable from their relationships with others; relationships are the core variable of care.
- A focus on care and responsibility within relationships, rather than rights, rules, and an abstract system of thought.
- A concern with the development of character and attitudes within the context of relationships.
- A concern for the rights and equality of all persons.

Thus feminist ethics allows a critique of the treatment of individuals in the contexts in which they live. This approach to ethics often focuses on imbalances of power along with oppression attributable to sex, sexual orientation, ethnicity, socioeconomics, politics, and other

characteristics. For example, a feminist ethicist might point out that a punitive approach to perinatal substance abuse is not associated with improved outcomes for the fetus; in fact, the fetus may be at greater risk because the possibility of such punishment makes women fearful of accessing health services.

The Ethics of Care

The feminist ethic of care is an important concept for health promotion because it focuses on the nature of nurse-person relationships and on the context of people's lives. This approach to care has found increasing acceptance in nursing as both a virtue of the nurse and a responsibility of practice in which treatment is offered on a common ground basis that will support people within their relationships. Carol Gilligan's (1982, 2013) research, among that of others, has been instrumental in the acceptance of the concept of care as informing ethics in nursing practice. Gilligan was a graduate student and then colleague of Lawrence Kohlberg, a developmental psychologist. The main focus of Kohlberg's (1981, 1984) body of work was the nature of moral character development, which was informed by Piaget's work on the stages of cognitive development in children. Kohlberg's stages of moral development were derived from longitudinal studies of young men. These moral reasoning studies were designed around the idea that an ability to apply conceptions of justice, rules, and principles to difficult situations denoted the highest achievable level of moral development. Gilligan challenged the reliance on only males in the study of moral reasoning and implemented studies of women's experiences, discovering that women had a moral orientation based on the caring and nurturing of others. In this framework used by women, interrelationships and contexts are critically important in understanding the complexities of a given situation (Paulsen, 2011).

The ethic of care calls for a knowledgeable and skillful health professional to assume responsibility for unique needs of an individual in all of his or her complexities. Benner and colleagues (2009) define care as "the alleviation of vulnerability; the promotion of

growth and health; the facilitation of comfort, dignity or a good and peaceful death," noting that care is "the dominant ethic found in [nurses'] stories of everyday practice."

Limits of the Ethic of Care

One problem with using care as an ethic of health-promotion practice has to do with the concern of moral predictability or certainty (Nelson, 1992), much like with Aristotle's virtue ethics. If the emphasis in ethics of care is on relationships and there are no criteria for right and wrong actions, how can one be assured of the morally correct action in a given situation? An answer to this question could be that a morally correct action emerges as a result of judgment based on prior knowledge, experience, and an engaged relationship with the person. Thus the process of the interaction, coupled with the character, knowledge, experience, and intent of the moral agent, is the crucial factor that achieves the moral good for an individual. A person's control of his or her own care is important. In a nursing setting the action is right if the nurse incorporates this person control into meeting the complex needs of the person being cared for.

When the solution to one person's problems affects others, however, the rightness of the action depends on more than the one-on-one caring relationship. The problem remains one of choosing between this person's needs and the needs of others who might be affected by the actions chosen. This problem is resistant to resolution via an ethic of care alone. The problem analysis framework described later combines the ethic of care with other considerations. Both an ethic of care and the principles derived from traditional moral theory may be needed for health promotion.

The purpose of ethical inquiry in health promotion is to gain clarity on actual or potential moral issues arising in the context of health-promotion endeavors and to understand what is expected of the health-promotion agent viewed as a moral agent. Ethical inquiry will not permit the resolution of all problems, because the environments in which health-promotion efforts are conceptualized are incredibly complex. It is impossible to foresee all possible consequences of

action, but ethical reasoning can facilitate appropriate and in-depth data gathering, permit the uncovering of hidden agendas and interests, and focus on the most salient aspects of a particular problem, thus enhancing professional judgment.

Professional Responsibility

Professional judgment and ensuing actions are integral to the goal of providing a good for the population of concern. Thus health promotion is a moral endeavor requiring morally sensitive and knowledgeable agents. But what are the scopes and limits of a nurse's obligations to anticipate, identify, and address morally problematic issues related to the promotion and protection of health for individuals, groups, and society? How do nurses balance their duties to individuals with a duty to the society? How are individuals' freedoms (autonomy) balanced with the collective responsibilities owed to society and future generations?

Accountability to Individuals and Society

Professions

Although this section focuses on the nursing discipline's mandate to promote health, the discussion can also be applied to the responsibilities of other health professionals who assume health-promotion responsibilities. Nursing is a profession insofar as it provides a service to society and is self-governing, and its members are accountable for their actions (Grace, 2001). A significant consequence of professional status is that members can be held accountable for their practice formally by professional licensure boards. More importantly, they are morally accountable for practicing according to their discipline's implicit or explicit code of ethics. One important characteristic of professions, especially those that provide crucial services to society, is that they have codes of ethics that provide essential elements of their promises of service to society. Codes of ethics provide a normative framework for professional actions. A professional implicitly accepts these codes on acquiring membership in the discipline. Thus each professional should establish a personal perspective on ethical practice within the broad framework of professional codes (Corey et al., 2014).

Trust

Service professions such as nursing, medicine, and teaching are in part defined by their relationships to those in need of services. This relationship is one of **trust.** The professional has the knowledge and skills to meet an individual's needs or the needs of a group. The potential recipients of services lack the knowledge or ability to anticipate or meet their own needs but trust that the professional will keep their best interests as the primary goal and will strive to meet their needs. For example, in the current health care environment in the United States, people may have trouble accessing a specialist provider because of their particular insurance coverage or the inability to afford health care insurance or to pay on their own.

Nurses are responsible not only for promoting health and healing but also for recognizing and addressing barriers to health-promotion activities. "Nursing's Social Policy Statement" (ANA, 2010) provides a detailed account of the nursing discipline's responsibilities, which describes the social contract between society and the nursing profession and emphasizes the nurse's responsibility to advocate changes when health care services are threatened.

Codes of Ethics

Codes of ethics are examples of normative ethics in that they prescribe how members of a profession ought to act, given the goals and purposes of the profession related to individuals and society. The provisions of codes of ethics for nurses provide direction and expectations of ethical behavior. They represent the profession's promises to society. Although the public is not directly involved in the formulation of such codes and, indeed, is for the most part not even aware of their existence, the profession is responsive to the evolving needs of a given society. It can be said that codes of ethics are the tentative end results of a discipline's political process in that they are not static but result from debate and discussion over time among the profession's scholars, leaders, and members.

The current *Code of Ethics for Nurses with Interpretive Statements*

presents a central foundation to guide nurses in their decisions and conduct (Epstein & Turnerm, 2015). The code establishes an ethical standard that is nonnegotiable; that is, the goals and intent of the code may not be ignored, diluted, or downplayed by individuals or institutions employing nurses in the United States (ANA, 1994). The 2015 code "addresses individual as well as collective nursing intentions and actions; it requires each nurse to demonstrate ethical competence in professional life" (ANA, 2015).

Codes of ethics tend to offer guidelines not only about responsibilities for ensuring good care but also about responsibilities for recognizing and addressing barriers to service. The ANA's *Code of Ethics for Nurses with Interpretive Statements* proposes that "the nurse promotes, advocates for, and protects the rights, health, and safety of the patient" (ANA, 2015, Provision 3). These actions would require a nurse to anticipate future health needs and political activity when necessary to ensure health promotion.

Advocacy

Advocacy, as an expectation of nurses, is strongly reinforced both in the *Code of Ethics for Nurses with Interpretive Statements* and in innumerable scholarly articles. However, advocacy is a controversial concept. The meaning of the term *advocacy* is derived from its use in law. In legal jurisprudence, advocacy is aggressive action taken on behalf of an individual, or perhaps a group viewed as an individual entity, to protect or secure that individual's or group's rights. The individual lawyer does not have an opposing obligation to attend to social justice issues. This attention to broader questions of justice is the responsibility of other areas of the justice system.

Nurses and other health care professionals have a responsibility to speak up on behalf of people whose rights have been compromised or endangered. This is part of the nurse's role because people may not recognize either what is needed to meet their needs or when the care they are receiving is substandard. However, that is not the end of their responsibilities. They must also consider that specific actions they undertake in the name of advocacy may pose problems for other

people who are relying on them for health care services.

For example, Juanita Rimmer, a nurse case manager, is assisting Jim Bailey to apply for services in a rehabilitation facility because he has residual hemiparesis secondary to a cerebrovascular accident. There is a waiting list at the facility, but Juanita believes it is a priority for Jim to be treated there because he lives with his frail, elderly mother, who will not be able to assist him with his activities of daily living. Because Juanita represents other people who will also benefit from rehabilitation, her decision to be an advocate for Jim must be weighed against the needs of these other people. A moral responsibility associated with advocacy in health care settings is that the effect of actions on others is considered. When one is advocating extra attention or specialized care for a given person, an injustice may be rendered simultaneously to other people in the nurse's care. Thus professional advocacy requires a balancing of the health needs of the individual with the health needs of the population (Grace, 2001).

Advocacy is an ideal of health care professions that requires attention to vulnerable individuals and groups and to broader societal concerns. **Moral agency** on the part of the nurse requires action and motivation directed to some moral end that is enacted through relationships. Being aware of one's self in relation to others helps to establish the moral choice required to be an advocate for them. Understanding the interdependent nature of individual and social needs facilitates preventive and health-promotion actions on the part of nurses both locally and globally.

In the last decade there has been a shift in global consciousness in both ethics and nursing, in which nursing views ethics in a much broader sense than just direct care provided to individuals (Tschudin, 2010). It may encompass such issues as unequal care in communities composed of a large minority population or for undocumented patients. Advocacy may include political activity to address populations of concern. Preemptive and sociopolitical advocacy identifies and challenges the source of the ongoing problems. Nurses have moral obligations related to sociopolitical advocacy on behalf of their populations of concern. Juanita Rimmer's obligations include

recognizing the problems caused by a chronic shortage of rehabilitation services. Her concerns include discovering the source of this problem and joining with others in an attempt to address it at this level. Strategies for solving seemingly intractable problems of health care include collaboration with specialty nursing, medical, or client advocacy groups, and communication of the issues in both professional and popular media.

Advocacy for health promotion is a concept with broad implications. It includes activities that are directed toward remedying socially based inequities or inadequacies in the health care delivery system. Advocacy can be viewed as an ethic of practice that includes all activities directed toward the person's good. Advocacy carries risks, in that addressing or facilitating the good for individuals or groups may pit nurses against their peers or against potential adversaries who do not share the same professional goals.

The nurse's role of advocacy requires that professional knowledge and judgment be applied to a variety of situations, from the relatively simple to the complex. The 2010 Institute of Medicine report “The Future of Nursing: Leading Change, Advancing Health” emphasized the need for advocacy in nurses through practicing to the fullest extent of their education and training and as full partners with physicians and other health care professionals in redesigning health in the United States (Institute of Medicine, 2010). This process requires several steps. First, potential or real problems need to be identified and analyzed, often in collaboration with others. Second, appropriate actions need to be formulated and their likely consequences considered. Third, obstacles to action should be recognized and addressed. Finally, actions are performed and evaluated. These basic steps are evident whether the object of health care or health promotion is an individual, a group, or society.

Problem-Solving: Issues, Dilemmas, Risks, and Moral Distress

The nature of health care environments makes it inevitable that

difficult decisions will have to be made. However, many of the ethical problems encountered in health-promotion settings are issues rather than dilemmas. Daniel Chambliss (1996), a sociologist who studied nurses in acute care institutional settings, asserts that organizations such as hospitals often give rise to "practical problems, not individual dilemmas." These practical problems are nonetheless moral problems because they interfere with the goals of promoting health, well-being, or the relief of suffering. In both institutional and noninstitutional health care settings, obstacles to good care may be caused by health care system arrangements, interprofessional conflicts, and/or lack of resources. Dilemmas are **ethical issues** of a special sort. **Ethical dilemmas** are those situations in which a choice must be made between two undesirable options. Weston (2010) claims that true dilemmas are actually quite rare and that often additional, better options can be found by one changing the way the situation is examined.

The goals of health promotion require that both issues and dilemmas be recognized and addressed. Neglected issues can become dilemmas. Because nurses are at the front line of providing health care, they are often the first to observe an issue with quality of care or safety. Sometimes this concern may lead the nurse to assume the whistle-blower role—bringing the concern into the open in the hope of effecting change. Various studies have identified whistle-blowing as key in highlighting a need for health reform (Jackson et al., 2014). There is considerable evidence, however, that the whistle-blower may experience significant negative and harmful consequences, such as being victimized or ostracized by colleagues and administrators or losing employment (Jackson et al., 2014).

When a nurse is in danger of losing his or her position as a result of advocating better conditions, a balancing of foreseeable risks and benefits to the individual or group is required. The process of decision-making in this situation can lead to moral distress. **Moral distress** occurs when a nurse knows the ethically correct action to take but feels powerless to take that action (Epstein & Delgado, 2010). Nurses who are faced with ethical issues that seem to be irresolvable

may experience guilt, frustration, and a sense of powerlessness, sometimes because they do not believe that they can adhere to their personal values. Moral distress can occur when the nurse's values and perceived obligations conflict with the needs and prevailing views of the work environment. The framework for making ethical decisions that is discussed later in this chapter includes considerations related to personal security along with preserving integrity.

Preventive Ethics

Just as preventive health care activities aim to forestall health problems, the practice of **preventive ethics** aims to forestall ethical problems before they develop. Preventive ethics is an important requirement of health-promotion endeavors that includes individual action by the nurse, as well as social and political activism with other nurses or professional nursing organizations. Preventive ethics requires the health promoter to envision potential problems and institute actions that halt their development. For example, it is possible to extend a dying person's life for a very long time with use of available technology and medications. Although a competent person has the right to refuse treatment and this right is legally recognized as a result of the Patient Self-Determination Act (PSDA) of 1991, many people become incapacitated before they are able to make their wishes known. All states recognize and honor advance directives, but the legally recognized form differs from state to state (Box 5-5). It is important to think about the nurse's role in supporting individuals and their families in end-of-life decision-making. Much more work needs to be done engaging people in discussion and helping them plan for such eventualities while they are still well. Preventive ethics in this situation entails initiating communication with persons and families before a problem arises. This communication is often missing both in institutional and in primary care settings.

Box 5-5

Preventive Ethics: Patient Self-Determination Act and Advance Directives

Advance care planning is a process in which patients, their families, and their health care providers discuss the patient's goals, values, and beliefs and document how these should be reflected in future health care choices. It often cannot be predicted whether and when individuals will lose the ability to make their wishes for treatment and care known. Advance care planning is a health-promotion endeavor that can enhance an individual's quality of life, especially while having chronic illness.

In the last 2 to 3 decades, great technological and therapeutic advances have been made, with the resulting ability to save the lives of people experiencing catastrophic illnesses and trauma. One effect of these advances, unfortunately, is that sometimes we are successful only in prolonging the dying process. Although it is now recognized that people have a right to refuse treatment to prolong life, critically ill people may lose their ability to articulate their wishes for treatment. Advance directives are a way for people to help ensure that when they become incapacitated, the care and treatment they receive matches their predetermined wishes. At their best, advance directives have the potential to ease the strain felt by loved ones as they strive to make the “right” treatment choices for a friend or relative. Advance directives also guide health professionals in their decision-making regarding the person in question.

Types of Advance Directives

There are various forms of advance directives but the types typically recognized by state law in the United States are the living will and the durable power of attorney for health care. Living wills document patient preferences for life-sustaining treatments and resuscitation, whereas a durable power of attorney documents one's choice of a surrogate decision maker. A major limitation of the living will is that it may not be applicable to every decisional dilemma the patient will actually face. Therefore it is important to also designate a surrogate decision maker who can provide guidance to health care

professionals in cases where patients are incapacitated and the living will does not apply.

The Patient Self-Determination Act (PSDA) of 1991, which was formulated in response to 2 decades of ambiguity and litigation involving right-to-die cases, represented an attempt to ensure that people's rights were honored. The PSDA required changes in public policy, public and professional education, institutional policy, and social awareness. The PSDA was intended to improve communication related to end-of-life care issues and preferences among individuals, health care providers, and proxy decision makers. It requires institutions that receive Medicare and Medicaid funds to:

- give written information on admission to all (not just the Medicare and Medicaid) persons about their rights under the law to make their own treatment decisions;
- inform people of their rights to complete state-allowed advance directives and provide written policies about those rights;
- document when a person has an advance directive;
- not discriminate or make care conditional on the presence or absence of an advance directive;
- provide staff education about advance directives and personal rights.

Although the PSDA has great potential, it serves its purpose only to the extent that it is taken seriously as a responsibility of a given institution. Institutions may fail to ensure that a qualified person is available to impart the information or to request personal preferences. It is important for those involved in health promotion to understand and address why people may be reluctant to make an advance directive and why institutions are not diligent in providing information and education. Recent studies suggest that the

percentage of older Americans who complete advance directives before their death has increased dramatically from 20% to approximately 70% over slightly more than the past decade but it is important to explore why, even in the presence of the PSDA, some people do not have advance directives.

Impediments to the Use of Advance Directives

- Discussions with health care providers about the implications of desired choices have been inadequate.
- People do not want to talk about future incapacity or death. They may have cultural prohibitions about discussing the possibility of serious illness or death.
- Past encounters with the health care system have led to distrust.
- People cannot predict accurately their future preferences and they know too little about what constitutes life support.
- People may change their minds about what they will accept.
- The health care proxy may turn out to be a poor choice or may cause conflicts among other family members or loved ones. The person or family may ask for something that is morally unacceptable.
- Treatments may be specified to which the provider has conscientious objections.
- Documentation may be lost, misplaced, or not accessible in an emergency.
- Written instructions are too vague and open to divergent interpretation to be useful guides.
- Even the most diligent proxy cannot always know what the person would have wanted in the absence of a detailed treatment directive.

- The proxy may make a treatment choice contrary to the person's directive.
- The proxy may make a decision with which the institution or physician disagrees.

Positive Outcomes of Use of Advance Directives

In spite of impediments, research has shown that advanced care planning has resulted in the following positive outcomes:

- Higher rates of completion of advance directives.
- Increased likelihood that clinicians and families understand and comply with a patient's wishes.
- A reduction in hospitalization and intrusive treatments at the end of life.
- Increased utilization of hospice services.
- Increased likelihood that patients will die in their preferred place.

Preventive ethics using a feminist ethics perspective would encourage the addressing of institutional practices to provide more humanistic care and underlying social issues that lead people to overeat, smoke, or be inclined toward violence. For example, preventive ethics would require the investigation of why as a society we have trouble discussing death and dying, and why we find it so hard to have a peaceful or good death. Weston (2010) notes that much of the energy used on the polarized abortion debate could be more profitably put to use in determining why people who do not want to be pregnant nevertheless become pregnant. Weston suggests that it

would be useful to reframe the question to ask "why pregnancy, or pregnancy at the wrong time, is so unacceptably burdensome for many women." We need to ask questions about lack of support, lack of education, poor or difficult-to-use birth control methods, resistance from spouses and lovers, lack of child care, and so on. One strategy for identifying potential ethical problems before they occur or worsen is to examine problematic cases for their antecedents. We should ask fundamental questions about societal arrangements and influences on health trends.

On a local level, nurses and other health promoters need to use clinical judgment in anticipating and forecasting problems before they arise. For example, unrecognized health illiteracy may affect an individual's understanding of his or her rights and entitlements. When a nurse observes that a person and that person's family do not understand either the information that has been given to them or the implications of following a given course of action, the nurse engages in preventive ethics by supplying that information and ensuring that the information is understood. The nurse acts to prevent negative consequences that can arise as a result of poorly understood information. Other examples of opportunities to use preventive ethics include focusing on smoking or childhood obesity. Many problems in health care occur as a result of poor communication or because information has been provided too late for reasoned decision-making (Box 5-6: Quality and Safety Scenario).

Quality and Safety Scenario

Patient-Centered Care

Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for the patient's preferences, values, and needs (http://qsen.org).

How Is Health Literacy Related to Ensuring Autonomy in Decision-Making for Individuals?

Autonomy is an important ethical principle for health-promotion activities. To ensure autonomy in individual decision-making, it is important to assess the individual's health literacy skills. These skills relate to a person's ability to obtain, process, and act on basic health information. Think how difficult it would be for a person with low literacy skills to navigate today's complex health care system. Adequate health literacy is essential for accessing necessary health care services and for fostering effective decision-making.

In the process of implementing health-promotion activities, the nurse should first determine whether the person has adequate health literacy skills. This can be assessed with tools such as the Rapid Estimate of Adult Literacy in Medicine-Short Form (REALM-SF) or the Test of Functional Health Literacy in Adults (TOFHLA). It is important however, not to base an approach to health promotion solely on the results of one of these tools, which may not reveal the extent to which health recommendations may be misunderstood. The nurse should take the time to establish a rapport with the individual that includes fostering a sense of trust and openness for the person to ask important questions.

Unrecognized health literacy may interfere with individuals' rights to autonomy in decision-making because they may make a decision based on inaccurate information or may automatically accept the decision of the health care provider without deciding for themselves whether or not the decision is appropriate for their individual situation. Thus it is an ethical obligation of the nurse to make sure that effective communication is implemented. A public health approach founded on health promotion principles can provide a useful scaffold for assessing the health literacy of persons in the community. This can help to ensure that the person is in control and a full partner in health-promotion decisions that respect his or her preferences, values, and needs.

population health literacy assessment. *BMC Public Health, 15*, 215.

Ethical Principles in Health Promotion

Although the tenets of nursing's codes of ethics and standards of practice provide some guidance about the nature of practice and the manner in which services will be provided, they often leave some ambiguity about the best course of action in morally troubling situations. The use of principles derived from a variety of ethical theories, along with feminist insights or an ethic of care, helps to provide further guidance in decision-making in morally problematic health situations. Beauchamp and colleagues (2007) noted that ethical principles provide an important starting point for moral judgment and policy evaluation, but that principles alone are not enough. In other words, principles such as autonomy, beneficence, and justice often serve as helpful starting points in teasing out the tangled elements of complex issues, but taken alone they are usually insufficient for moral problem-solving in health care environments. One must decide which principles are important to consider in a given case or situation, and this requires an exploration of the case as discussed in the decision-making framework provided later in the chapter.

Additionally, tenets of the *Code of Ethics for Nurses with Interpretive Statements* and other ANA position statements provide guidance regarding what a nurse's moral responsibilities are in a particular type of situation. Certain tenets address the responsibilities of the nurse in improving the larger health care environment. These obligations include collaborating with others to "protect human rights, promote health diplomacy, and reduce health disparities" (ANA, 2015).

Autonomy as Civil Liberty

In health-promotion settings and endeavors the concept of **autonomy** can be understood from two different perspectives. From the vantage point of public health, the extent of individual autonomy, or freedom of action, may be limited by the duty of protecting the health and

safety of the society. From this perspective there is an age-old struggle between civil rights and public safety. Moral questions ask to what degree society is justified in regulating the health and safety of society at large. There is an inevitable tension associated with curtailing **civil liberties** in the name of safety or health. This tension arises from perceptions that, in most Western contexts, freedom of action is a prerequisite of human flourishing.

Currently there are many indirect threats to the health and safety of our society including, but by no means limited to, bioterrorism and the spread of HIV/AIDS and drug-resistant tuberculosis. Actions to resolve any of these threats have the potential to impinge on civil liberties; such actions might include, for instance, surveilling citizens or requiring disclosure of disease status. Advances in genetic knowledge present the possibility of discrimination from a variety of sources. It will be difficult to maintain individual privacy, and discrimination based on class or gene profile will be made easier.

The current managed care environment, although having a stronger focus on inculcating healthy behaviors, can impinge on civil liberties. The behavior-change approach has been criticized as too paternalistic, without sufficient regard for the individual's or the group's own perceptions of what is important; this may increase the risk of failed interventions. Prioritizing behavior change in health-promotion endeavors over the need to address underlying social concerns, such as poverty and other forms of disadvantage, may obscure a focus on the social determinants of health. Rather than focusing on behavior change, a focus on empowerment may help a person gain control over social and economic factors that contribute to health problems (Tengland, 2016).

Autonomy as Self-Determination

A second, related, sense of autonomy has to do with individual choice. Autonomy is the moral principle that underlies the concept of informed consent to treatment, interventions, and health-promotion efforts. In Western societies it is probably the most powerful moral principle underlying the treatment of individuals. This principle

asserts that people have the ability to reason, and a consequence of the ability to reason is the capacity to make choices. These choices concern both one's own behavior and how one should act toward others. Although the idea that our ability to reason constitutes the essence of being human originated with Aristotle, Kant (1993/1785) developed this idea in meticulous detail in his work *Grounding for the Metaphysics of Morals*. According to Kant, people are capable of conscious desires and goals and are free agents capable of making decisions and setting goals as guided by their own reason. This principle is a salient consideration in health care settings: it underpins the health provider and promoter-person relationship and the issue of informed consent. However, there is limited agreement about the scope, limits, and strength of this principle (Beauchamp & Childress, 2008). When describing autonomy in the context of health or treatment choices, we should delineate what we mean by autonomy in the context of the problem under discussion. Feminist criticisms of an emphasis on autonomy highlight the problem that our choices necessarily affect others because we are contextual beings inseparable from our relationships with one another.

Respect for human autonomy guides us to permit individuals to make and learn from their own mistakes. Generally, respecting autonomy requires that we permit individuals to make their own decisions, even when these decisions seem to others to be ill-informed. There are exceptions to this rule. Exceptions include those situations in which there is a high risk of serious injury or death and when it cannot be determined whether the person's judgment is impaired. Thus we make exceptions to the rule of autonomy when we suspect that an individual is not able to reason adequately. A person's reasoning ability may be impaired by psychological or physical conditions, or it may be impaired as a result of incorrect or incomplete information.

In health-promotion activities, respect for autonomy requires that individuals be given the information they need to make choices. Choices can be considered autonomous only if certain criteria are met. The criteria that determine whether or not a person is actually capable

of autonomous (voluntary) choice include cognitive maturity, possession of appropriate information to permit decision-making, intact mental capacities (the ability to reason logically), the absence of internal or external coercive influences, and the ability to appreciate the risks and benefits of alternative choices. Assessing all such criteria is quite a tall order. And in one sense it may be that nobody acts totally autonomously at any given time because of the influences of entrenched beliefs and values that are derived, for the most part, from our cultural and environmental backgrounds. We are never entirely escaped from Plato's cave. Some of these influences are under conscious control in the sense that we can recognize what values we hold and even revise them if they are dissonant with other values. However, some of these influences are not readily recognizable: they lie beneath the surface of consciousness and are hard to access even if we are willing to try. We all have blind spots; autonomy viewed as informed, uncoerced, and reasoned action is therefore an ideal. Many of us fall short of the ideal.

Informed Consent

Informed consent to research, treatments, or health-promotion endeavors is a process of ensuring that a person has all of the appropriate information necessary to reach a decision about participation that facilitates autonomous action. Beauchamp and Childress (2008) note that informed consent occurs when a person with substantial understanding, and without substantial control by others, intentionally authorizes a professional to intervene on his or her behalf. The key phrase is “with substantial understanding.” It is important to understand that even after a consent form has been signed, a person has the right to rescind consent in light of additional information and/or changed consequences.

The components of the **consent** process include determining the person's competency to consent. There must be no physical or mental impairments that hinder the person in question from understanding and processing information. For example, a person with pneumonia who is febrile and confused is probably not capable of making an

informed decision until the fever has been reduced and the confusion has cleared. To be substantially informed, a person must be made aware of important details of the proposed intervention, including its nature, purpose, probability of success, and important risks, and must also understand what alternatives (if any) are available. Because this information must be tailored to meet the specific needs of an individual and such a task requires knowledge of the person, an ethic of care is important to understanding a person's unique needs. We can check understanding to a certain extent by asking the individual to articulate how the proposed intervention will facilitate his or her own values and goals. There must be no subtle or overt coercion by professionals or others. Finally, appropriate supports must be available to complete the proposed intervention.

Obtaining consent for any interventions, or for involvement in research, is best viewed as a process that entails ongoing assessment of the person's status and evaluation of needs for further information or support. People may not understand information well when they are in stressful situations or when the information is complex. Thus we should assess people for and validate understanding on an ongoing basis.

Ensure that all individuals, regardless of age, make informed choices. Although the life span increases in society, nurses must be aware of strategies for ensuring that older adults, who may be less able to advocate their own health needs, participate in the making of informed decisions. More research is needed on ethical problems that confront nurses in caring for older adults in the community.

Adolescence is a period of transition between the dependence and vulnerability of childhood and the autonomy of adulthood. Adolescents are generally considered capable of making decisions related to health-promotion activities, and health professionals have a duty to respect those decisions, provided that doing so does not produce harm to adolescents or others (Larcher, 2012). Most health-promotion activities do not require formal informed consent. However, it is important to integrate the underlying principles and supporting research related to informed consent to be sure that the

selected health-promotion strategies fit individuals' beliefs and values. It is also important to recognize that complex social factors may contribute to adolescents' inability to make well-thought-out decisions (Box 5-7: Evidence-Based Practice).

Box 5-7

Evidence-Based Practice

Influences on Sexual Decision-Making of Late Adolescents

Violence has been identified by the World Health Organization as a major risk to the health and well-being of all young women. Sexual activity without clear consent is one aspect of violence against adolescents, who are still developing their values and beliefs about sexual activity and sexual norms. In a qualitative research study, Fantasia (2011) used a narrative inquiry approach to explore what influenced adolescents' decision-making related to sexual activity. The research question was: What are late adolescents' perceptions of factors that influenced their sexual decision-making? Ten female adolescents aged 18 years or older were interviewed. They were asked to respond to the question "Please tell me, in your own words, the story of your decisions to have sex." Each participant constructed her own story without influence from the researcher.

The findings showed that in the most of the sexual encounters of these adolescents, sexual consent was implied, with no consent clearly stated. The participants discussed how sexual activity eventually occurred, even when they did not want it, because of partners who used "pressure to always say yes." Inability to communicate readily with partners and the influence of alcohol were identified as contributing factors to the lack of clear consent. None of the participants expressed emotion or anger over what had occurred, and they did not label it as rape. There appeared to be an acceptance of this type of nonconsensual sexual activity.

The findings from the study provide evidence that adolescent decisions involving consent for sexual activity are complex and are influenced by a myriad of social factors. All individuals have a right to clearly refuse or consent to sexual activity; this is imperative for the promotion of physical, emotional, and sexual health and safety. Nurses and other health care professionals who work with adolescents need to carefully assess sexual behaviors and recognize that these young women are at risk of nonconsensual sexual activity. Sexual violence education should include information on negotiation and communication skills that will help adolescents mediate complicated interpersonal situations. Appropriate educational programs can help to empower young women through opportunities for increased knowledge and self-confidence.

Exceptions to Autonomous Decision-Making

In some cases, proxy decision-making on behalf of the individual is required (Box 5-8). Proxy decision-making must take into account what is known about the person and must follow a path of action that is most likely to respect that individual's goals and values. Researchers have found that surrogate family members who need to serve as proxies in making decisions for loved ones, often at the end of life, find the decision-making overwhelming and extremely stressful (Sorrell, 2014). Most surrogate decision makers have had little preparation for making these choices and worry that they are not making the right decision. Nurses should support these surrogate decision makers as they struggle with making a decision. Iverson and colleagues (2014) described what helps and hampers surrogate decision-making (Box 5-9: Innovative Practice).

Box 5-8

Proxy Decision-Making

Autonomy based: person's previously articulated desires

- Written

- Living will, advance directive

- Document details to various degrees what the person will or will not accept

- Substituted judgment

- Individual appoints a proxy who is expected to honor previously expressed preferences

- Informal (nonappointed significant other)

Best interests

- Surrogate chooses the actions that will give the highest overall benefit—may or may not be based on a person's previously expressed desires; a quality of life determination based when possible on knowledge about the person (Beauchamp & Childress, 2008)

- Best interests may trump the proxy's choice; doubt about the proxy's motives possible

Reasonable person standard

- Based on the answer to "What would a reasonable person want?"

Innovative Practice

Surrogate Decision-Making

Most end-of-life health care decisions are made by surrogate decision makers who are under a great deal of stress over their seriously ill family member. Both surrogates and clinicians have various degrees of preparation, knowledge, abilities, or comfort in working effectively with another in making very difficult decisions for someone else.

Iverson and colleagues (2014) explored surrogate decision makers' challenges in making decisions related to the care of patients in critical care. They interviewed 34 designated surrogates of critically ill patients receiving care in two tertiary care institutions. Surrogates were asked to describe and reflect on their experiences of making health care decisions for others. They identified factors that added to the difficulty in decision-making:

- Stress associated with assuming a decision-making role for which they felt unprepared
- Uncertainty of patient outcomes
- Difficulty in communicating with multiple health care providers who would provide different information
- Insufficient knowledge of patients' wishes
- Conflict within the family
- Fatigue resulting from near constant vigilance in the intensive care unit

Social networks that provided access to family and/or friends were helpful in the decision-making process, as they provided surrogate decision makers with emotional and informational support. Nurses were the preferred resource for day-to-day communication and information gathering except when major decisions needed to be made. Most participants perceived that nurses offered compassionate

communication and were able to disentangle information that was difficult to understand.

The findings of the study suggest areas where clinicians can intervene to facilitate the processes of surrogate decision-making. Stress can be minimized by improving communication between surrogate decision makers and health care providers. Nurses are uniquely poised to intervene to improve communication and reduce surrogates' decision-making anxiety.

Certain populations are considered less than fully autonomous for a variety of reasons. People with Alzheimer disease or other physical or psychological disruptions or deficits that prevent adequate comprehension may require proxy decision makers. It is important not to assume, however, that all persons with Alzheimer disease are incapable of providing informed consent, because many persons in the early stages of the disease are capable of making decisions related to their care (Sorrell & Cangelosi, 2009). Incarcerated people are restricted in their choices and may be subject to subtle or not-so-subtle coercion. Children are considered less than fully autonomous because they are not developmentally mature. Additionally, in people with certain mental illnesses, such as psychoses or bipolar disorders, the capacity for decision-making may fluctuate. The President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research (1982) was formed to study health care decision-making and noted that the minimal capacities needed for competent decision-making are "(1) Possession of a set of values and goals; (2) the ability to communicate and to understand information, and (3) the ability to reason and deliberate about one's choice." These criteria are generally accepted as a basic minimum (Beauchamp & Childress, 2008). It can be seen from these criteria that some children would be able to understand the implications of a given course of treatment, and adults with cognitive impairments may be

deemed competent to make certain decisions. Competency to make autonomous choices is not an all-or-nothing capacity. Competency determinations are, as a rule, made for a given decision or task. Thus a person may vacillate between competency and noncompetency, depending on either the task at hand (degree of difficulty) or the physical or psychological status during the period when a decision must be made.

When advocating decision-making for a cognitively impaired person, consider the risks and benefits of allowing the individual to make his or her own decision. The benefits in terms of self-esteem may well outweigh the risks of many choices. However, if the risk of injury is high and it is obvious that the person is not able to reason effectively, autonomous decision-making may not be feasible. In this case, nurses can collaborate with the individual, family members, and other health professionals to arrive at a decision that is best for the individual.

When children are involved, it is often the parent or guardian to whom we turn for permission to treat the child. Nevertheless, in pediatric settings it is incumbent on people involved in health-promotion endeavors or in research with minors to gain assent from the child in addition to consent from the parent or guardian (Driessnack & Gallo, 2011; Lambert & Glacken, 2011). The example of 5-year-old Julianna Snow illustrates how difficult these decisions can be. Julianna had an incurable neurodegenerative illness and decided that she would rather die at home instead of returning to the hospital for treatment that would likely lead to death or being sedated on a respirator with little quality of life. Julianna's parents honored this decision and Julianna died. Ethical questions were raised about whether a child of this age could/should be allowed to make an irreversible decision without the maturity to understand the consequences (Cohen, 2015).

For a child's assent to be meaningful, an assessment of the level of maturity and comprehension is required, and information must be provided in language and terms that are appropriate for the developmental level. Conversely, when there is conflict between the

decision of the parent and that of the child, the health care provider has a duty to ensure that the parental choice is in the child's best interest. Where there is serious doubt, it may be necessary to involve the courts.

Confidentiality

Autonomy is also the principle underlying **confidentiality:** One expression of autonomy is the ability to maintain privacy in one's life (Burkhardt & Nathaniel, 2013). People have the right to decide who can have access to information about them, thus limiting the negative use of personal information by others. In certain situations, the status of confidentiality between a person and others, such as clergy, is considered a privilege and as such is shielded from exposure by the legal system. In health care, confidentiality does not carry as strong a status as clergy-supplicant or lawyer-client privilege (Grace, 2004). There may be occasions when health care providers have a duty to warn others who are unknowingly endangered. This duty was highlighted by the landmark Tarasoff case. On October 27, 1969, Prosenjit Poddar killed Tatiana Tarasoff. Poddar was receiving psychiatric care during this period. He had informed his therapist 2 weeks earlier that he was going to kill a certain girl, easily identifiable as Tarasoff, on her return from Brazil. At the time his therapist tried to have him committed. The police detained Poddar briefly but decided he was rational, so they released him. No one warned Tatiana of the danger. The courts concluded that "once a therapist does in fact determine, or under applicable professional standards reasonably should have determined, that a person poses a serious danger of violence to others, he bears a duty to exercise reasonable care to protect the foreseeable victim of that danger" (Tarasoff v. Regents of University of California, 1976). The court recognized the difficulty of predicting the degree of danger and the importance of maintaining confidentiality but determined that when the risk is high, confidentiality should be breached.

Nurses must strive to keep the person's personal information confidential so as to enhance trust within the nurse-person

relationship. Therefore in health care settings there are strong penalties against breaching confidentiality. In theory, the principle of confidentiality may be overridden only in situations in which extreme harm to self or others is imminent. In practice, this is difficult to enforce, because in medical settings many people have access to the person's information. Insurance companies demand access to information before payment for services is made. In outpatient settings, challenges for privacy may occur when personnel are personally acquainted with the individual. When health professionals are members of the community in which they practice, there may be confidentiality issues associated with the intimate nature of small communities. Nurses and other health-promotion professionals may find themselves being asked by friends and relatives of the person for details about that person's health status. It can be very difficult to respond diplomatically while maintaining the person's privacy. The ethical implications of these threats to confidentiality are many. Thus it is important for nurses to be aware of potential breeches of confidentiality and to advocate confidential treatment of information for those they serve.

The Privacy Rule

The **Privacy Rule** (45 Code of Federal Regulations Part 160, 164 subparts A & E) was developed as a result of the Health Insurance Portability and Accountability Act (HIPAA). Its intent was to ensure that individuals' health information is properly protected, while allowing the flow of information needed to provide and promote high-quality care (including use of information about the person receiving care for research) and to protect the public's health and well-being. HIPAA was meant to protect the privacy of individually identifiable health information in the face of advances in electronic technology and to limit the ways in which “health plans, pharmacies, hospitals, clinics, nursing homes and other covered entities (any provider that conducts or conveys information in electronic form, e.g., physicians, nurse practitioners)” can use medical information (US Department of Health and Human Services [USDHHS], n.d.).

“Covered entities” means those covered by the Privacy Rule. The limitations on the use of medical information extend to any identifiable information, written, oral, or computerized. Although there are some legal guidelines about disclosure, nurses and others are responsible for using clinical judgment in deciding what level of detail to share. It is important to understand that the purpose of the rule is to protect individual rights while still facilitating important public health and epidemiological research. Health-promotion activities include empowering people to exercise these rights. The Privacy Rule ensures that individuals are given a copy of the privacy practices at a given institution. Additionally, under the rule individuals have the following rights:

- To access their own information.
- To limit who may receive their information.
- To request corrections for errors.
- To receive an accounting of how their information has been used.
- To request special confidential reporting of their information to them at a location of their choosing (this may be especially important for individuals at risk for intimate partner violence).
- To pursue complaints with the Department of Health and Human Services Office for Civil Rights.

A rule of thumb for health professionals related to sharing information with others is to disclose only as much information as is pertinent to the situation and is necessary to provide optimal care. A decision about disclosure of a person's information requires balancing of the risks of information sharing with the benefits of treatment. Although the Privacy Rule was meant to help safeguard people's rights, some commentators and researchers are finding the rule overly restrictive and worry that it might discourage important research, especially genetic research, with its far-reaching implications for individual privacy.

Adolescents: Special Considerations of

Confidentiality

Adolescents often present health professionals with very tricky confidentiality issues. As Bandman and Bandman (2001) note, "the adolescent is torn between wanting to challenge authority and to assert independence while still needing the help and support of effective parents. Normal developmental needs, along with the results of risk-taking behavior such as drug and alcohol experimentation and risky sexual activity, mean that teenagers can pose a health-promotion challenge. The task of health promotion is to maintain and facilitate the adolescent's emerging autonomy and confidentiality needs, while mediating between the peer and parental figures who feel that they have a right to information about the adolescent. It is easy to become caught in the tension between the anger and perceived duties of the parent and the defensiveness and vulnerability of the adolescent" (Bandman & Bandman, 2001).

Although federal and state laws, as well as ethical considerations, generally serve to protect the privacy and autonomy of adolescents, health promotion involves more than mere protection. It involves facilitating the adolescent's health. Thus the responsibilities include helping an adolescent to grasp his or her authentic options and rights, facilitating interaction between the adolescent and parents or guardians, maintaining trust, and preserving confidentiality.

On the other hand, clinical judgment (which includes ethical judgment) is important in determining risk. If the risk of preserving the adolescent's privacy is high, on the basis of all pertinent and available evidence such as the presence of sexual or physical abuse, then it may be necessary to report this information to appropriate authorities. Mandatory reporting laws exist. Such laws are important for the general protection of a society's citizens. However, there may be rare occasions when a judgment must be made about whether upholding the legal obligation would cause more harm than good. In such circumstances there are two separate considerations. First, one must decide whether the risk to professional standing and licensure of not following the legally required path is something that the professional is willing to assume. The second consideration involves

assessing the potential benefits and risks to the person resulting from failure to report. There is no easy resolution for these types of problems. If the situation is not an emergency, it is prudent to solicit appropriate advice from a peer, a counselor, or an ethics expert or resource. In any case, it remains the professional's ethical responsibility to handle the given situation in a manner that preserves trust and provides ongoing support.

Veracity

Veracity, or devotion to the truth, is another principle that supports health-promotion activities. People whose health is in question are to various degrees reliant on the person who possesses the knowledge and skills to bring these to bear on their behalf. The contemporary bioethics literature favors characteristics of "veracity, …candor, honesty and truthfulness" (Beauchamp & Childress, 2008) as virtues to be nurtured in the development of health professionals. This represents a change from the paternalistic (the physician knows what is best) attitudes that prevailed early in the 20th century and up to the late 1960s.

Veracity in giving people information about their health care needs facilitates autonomous choice and enhances personal decision-making. Nurses may be tempted to withhold certain details when this is seen as serving the person's best interests or when family members demand it. It is sometimes difficult to determine how much and what types of information will best serve a person's needs. Knowledge of the person's beliefs, values, and lifestyle preferences is essential to the process of supplying adequate information to support autonomous decision-making. Withholding information or providing information that is misleading or incomprehensible in an attempt to influence someone to agree to a treatment or intervention conflicts with veracity. It may be tempting to avoid the longer route to resolving such problems (e.g., education, understanding people's motives).

Veracity has some cross-cultural implications, in that some cultures have not traditionally valued truth-telling in the case of terminal illness. Decision-making about whether or not to honor veracity in

such cases must take into consideration what is known about the culture, the particular person, the strength of his or her personal and cultural beliefs, and whether there is evidence about what sorts of things the person would like to know. The absence of veracity may interfere with autonomous action. In the case of terminal illness, it may deprive the person of the ability to plan the remainder of his or her life.

At first glance, veracity appears an easy concept to incorporate into health-promotion interventions. It may sometimes be difficult, however, in health education endeavors aimed at changing patterns of behavior in society. Should health professionals just present the facts or should they attempt to persuade people? What are the limits of veracity? Is it permissible to exaggerate the dangers of certain behavior in the interests of the health of society? These questions cannot be answered within the confines of this chapter but are important to keep in mind when one is assessing the merits of proposed population-based interventions.

Nonmaleficence

Related to autonomy is the principle of **nonmaleficence,** which enjoins people not to harm other people. In general society, this principle constrains people from autonomous actions that are likely to harm others. For instance, a 25-year-old is allowed to drink alcohol but not to drink and drive because the latter may harm others. In health care settings, this principle prohibits clinicians from harming those for whom they provide services. For health promotion, it means that when activities are being planned on an individual or societal level, possible harms must be minimized. It is often impossible to foresee all the risks of a given course of action, but professionals who engage in health-promotion endeavors are responsible for foreseeing predictable adverse consequences and taking these potential consequences into consideration. The responsibilities include addressing social or health care policies that are discovered to have unintended effects.

Carter and colleagues (2011) illustrate how a policy designed to

address obesity through use of a mass-media program can have unintended negative health effects. They describe how the program *How Do You Measure Up?* can carry the message to people to trim waistlines and "turn their lives around." Although mass-media campaigns such as this one are targeted at the population level, they may also have a deeply personal and emotional effect on individuals, stigmatizing individuals who feel incapable of making changes in their lives to lose weight.

Teaching about self-esteem and fitness may help people live with obesity more healthfully. Employer incentive programs that differentiate among individuals on the basis of their success in changing behaviors such as smoking or weight loss also carry the possibility of discrimination when they provide financial benefits to the most successful individuals, in that some individuals face significantly greater difficulty than others in achieving desired outcomes (Madison et al., 2011). Well-designed employer incentive programs, however, can help individuals overcome barriers they face in trying to avoid disease and disability. Systematic evaluation of incentive programs will enhance understanding of how to design programs to prevent discrimination and maximize equity (Sorrell, 2015).

Unintentional harm is a possibility for actions designed to promote health. Risks can be minimized by anticipation of potential negative effects and implementation of measures to control them. Professionals are responsible for understanding the limits of their knowledge or the data to which they have access. A synthesis of reflection, critical thinking, and knowledge, along with an understanding of the details and context of a situation, is required before one embarks on a course of action aimed at facilitating a person's health or well-being. The overall discomfort encountered by the individual must be the minimum possible to achieve the primary good intended. In other words, the health care provider is accountable for his or her judgment and for providing interventions most likely to bring about the desired result. Thus more than just the intention not to do harm is required.

Nurses and other health professionals can do harm inadvertently

through such behaviors as ignorance or incompetence, referral to a provider who is incompetent or inappropriate, or inadequate supervision or training of those under their supervision. However, the duty of nonmaleficence does not mean that nurses are always accountable for foreseeing the consequences of their actions. For example, a course of exercise may be designed for a person who has had a thorough physical examination, but during an exercise session the person faints and fractures his arm. Further testing reveals a previously undetected cardiac anomaly that is subsequently surgically corrected. This is not **maleficence;** the main objective of the agent was therapeutic, and the event was, if not totally unforeseeable, not identified on routine preexercise testing. In this kind of case, we tend to look at the principle behind the action rather than the consequences. The clinician's duty was upheld, even though initially bad consequences were the unintended result. Thus both deliberate harm and harm caused by indifferent or incompetent decision-making should be considered maleficent, but when a competent practitioner evaluates a problem thoroughly in its appropriate context and intervenes with therapeutic intent, and nonetheless there is a partially negative outcome, such action does not violate the concept of nonmaleficence.

Beneficence

Beneficence is the quality or state of doing or producing good. As a moral principle, beneficence presents us with the duty to maximize the benefits of actions while minimizing harms. There are two related aspects of the moral principle of beneficence in health-promotion settings: actions taken to further the overall health or well-being of the society in general and actions taken to promote the good of a particular individual.

When society formulates rules designed to protect people against the negative effects of their own actions, these rules are considered beneficent. It is important to emphasize, however, that beneficence should be performed in accordance with the person's will or values, and with respect for the person's autonomy (Kangasniemi, 2010;

Keane, 2010). Sometimes rules designed to protect people are described as paternalistic because they override a person's autonomy to disobey them. For example, motorcycle helmet laws are paternalistic, as are rules governing the use of therapeutic or so-called recreational drugs. **Paternalism** is often justified by the assertion that the persons affected will be better off or protected from harm.

The principle of beneficence, when it overrides an individual's autonomous choice so as to serve that individual's interests, is appropriate when a person lacks the capacity to make personal decisions. Thus any of the factors discussed earlier that interfere with rational decision-making may require the health care provider to beneficently override the individual's decisions. Generally, though, beneficence permits interference only when the risks of the individual's proposed actions are high. This is because autonomy is such a powerful principle in Western societies that a decision to override an autonomous choice is not taken lightly. One may be justified in preventing a person from taking an overdose of sleeping pills or jumping off a cliff because the risks of not doing so are high and, importantly, if the person succeeds there is no possibility of future autonomous actions.

Beneficence, unlike nonmaleficence, is not necessarily a moral requirement of action on the part of societal members toward each other (Grace, 2004). Whether beneficence is viewed as a moral requirement of societal members in everyday life very much depends on philosophical beliefs and the ethical theory or perspective (if any) recognized by the person. Kant (1993/1785), for instance, distinguishes between perfect duties and imperfect duties. Perfect duties must be followed and tend to be defined in negative terms (e.g., “do not lie,” “do not steal”); imperfect duties are ones we are called but not bound to follow (e.g., stopping to help someone who is looking for something lost on the sidewalk). An individual is not necessarily morally required to go out of his or her way to help someone unless the person is endangered and assistance would mitigate the danger. In that case, failing to offer assistance could be seen as violating the principle of nonmaleficence. Also, when an individual has

responsibility for vulnerable others, such as when parents must use beneficence on behalf of their children, beneficence is required.

In contrast to ordinary members of society, nurses have duties of beneficence because their professional goals involve meeting health care needs and thus are aimed at providing good. For such reasons, beneficence is a moral expectation of nurses. Beneficence is often a difficult principle to use in health-promotion settings, however, because of the dual nature of health-promotion goals—health for individuals and health for communities. As noted earlier, there is often a tension between the two.

A paradox exists when we try to change unhealthy behaviors but do not address the underlying causes of those behaviors. For example, although smoking cessation programs assist some people to stop smoking, and restricting areas where people may smoke tends to persuade some people that it is becoming too inconvenient to continue, we also should address problems such as advertising campaigns that aim to gather new smoking recruits from among adolescents. Some advertising campaigns encourage adolescents to try flavored cigarettes through offering a variety of flavors and attractive packaging. But these tobacco cigarettes are addictive and dangerous. Education-based health-promotion programs without underlying societal changes are often doomed to fail. Thus following beneficence, health professionals have obligations to address deep-rooted social problems that jeopardize health or are associated with health disparities.

Beneficence: Conflict With Autonomy

The principles of beneficence and autonomy sometimes conflict. For example, seat belt rules are ostensibly created to protect people from injury, but they take away autonomous choice. Beneficence may justify overriding the decision of a febrile, confused person who refuses to take her antibiotics for treatment of pneumonia. What is the clinician's responsibility? The duties of beneficence seem to mandate medicating her against her will, ensuring that the good of health is facilitated although violation of the principle of autonomy. The

justification for this must include an assessment of her status related to her capacity for autonomous decision-making. Preserving the person's life so he or she can make autonomous decisions in the future may be required by beneficence. However, it can be argued that beneficence takes precedence over autonomy only in those cases in which the choice cannot be considered autonomous. First, there has to be evidence that a choice has been made. In this case the choice was between accepting antibiotic treatment versus not accepting antibiotic treatment. Second, the reasonableness (or rationality) of the decision has to be discerned. It must be ascertained whether the person really has grasped the implications of refusing treatment. The reasons given for the treatment refusal, then, should illuminate gaps in information delivery or processing. Finally, it must be determined whether there are any external or internal coercion factors impinging on the decision. Perhaps the person feels she cannot afford the medicine (external), or perhaps she has a mistrust of antibiotics because of a previous experience (internal). When a decision cannot be said to be informed, the principle of beneficence directs us to decide on treatment on the basis of the person's best interests.

Justice

Justice is an ethical principle of major importance in health-promotion settings. There are various conceptions of justice, and the term is used in a variety of ways. For the purposes of this chapter the discussion is about social justice rather than criminal justice. **Social justice** includes formal or informal systems within a society that are concerned with disparities in socioeconomic conditions leading to poor health and fairness in the distribution of goods such as health, education, food, and shelter (Powers & Faden, 2008). Buchanan (2000) notes that the concept of justice has been central to human understandings of socially significant values for a long time. Justice in health care is a major commitment of nursing, and thus the discipline of nursing is becoming more focused on active engagement in social justice issues.

In democratic societies, the requirements of social justice generally include equitable distribution of the benefits and burdens of societal

life. “Justice as fairness” reflects the ideas behind Rawls's (1971, 1999) *A Theory of Justice*. Rawls identifies two rules that he argues will result in a fair and just society. “First: each person is to have an equal right to the most extensive liberty compatible with a similar liberty for others. Second: social and economic inequalities are to be arranged such that they are both (a) reasonably expected to be to everyone's advantage, and (b) attached to positions and offices open to all” (Rawls, 1971). Rawls formulates these rules as a result of his hypothetical method for deciding how a society's institutions should be arranged to provide fairness. Rawls proposes that these rules of justice would emerge as a result of an average person's reasoning about what social arrangements that person would prefer if that reasoning were done from behind a “veil of ignorance”; that is, if the person did not know what his or her personal impediments, assets, or characteristics were going to be, such as intelligence, socioeconomic status, race, gender, or (dis)ability. Rawls's two rules aim to balance overall good for society with respect for individual rights, in some ways a balance of Mill's utilitarianism and Kant's focus on respect for persons. That is why inequalities must be open to all and must be to everyone's advantage. It is arguably fair for a judge to be paid more than a janitor because the judge's higher salary is to the advantage of all because it leads to competition and motivates the brightest citizens to enter the profession. However, to truly be a fair situation, part (b) of the second rule would also have to hold true—the pathway to becoming a judge must be open to all. Meeting part (b) would presumably require, at least, quality public education and financial support for college and law school.

Rawls's theory, although respected by ethicists, is subject to criticism on a variety of fronts. One significant criticism is that justice as fairness does not provide much guidance for some common social problems, such as abortion, welfare, and the righting of previous wrongs (e.g., affirmative action, the rights of native people), and ignores the problems of those without legal rights such as undocumented workers (Buchanan, 2000; MacIntyre, 2007). Dinkins (2011), however, suggests that the “veil of ignorance” thought

experiment described by Rawls may increase empathy in daily practice because it helps us realize that when we step out from the veil into the workplace being envisioned, we could be anybody: a single mother without insurance unable to access health care for her children, an elderly woman with a hoarding disorder who lives surrounded by piles and piles of decaying garbage, or a person from any other vulnerable population in our society.

An emphasis on justice in health care settings is sometimes called the impartialist perspective in that it considers the needs of all who fall under its umbrella. For example, within the prison system, this view of justice would mandate access to care for prisoners in need. Thus it would not permit arbitrary obstacles to access (such as requiring good behavior or favors) that might be presented by prison officers or by other prisoners who wish to exert physical or psychological control. Justice would also require improved access to care for the poor and underprivileged, in terms of both receiving care and having access to transportation or local availability of services.

Although justice might require consideration of the special needs of a disadvantaged group, it does so impartially: that is, it does not distinguish among the particulars of individuals. Each member within the group has an equal right to whatever is proposed. In an economically and profit-driven health care system, injustices occur both at the local level and at the societal level. Because justice viewed as fairness is impartial about individual differences, that moral perspective considered alone is not a perfect tool with which to look at health care disparities and their causes.

Health disparities are a specific subset of health differences that are important for social justice because they evolve from intentional or unintentional discrimination or marginalization (Braveman et al., 2011). Nurses and other health professionals need to move beyond thinking about "doing no harm" to identifying and addressing adverse social influences on the health of underprivileged groups and the implications of their consequent poor health (Rogers & Kelly, 2011). The combination of justice, feminist concerns about power and oppression, and the acknowledged responsibilities of nurses to

promote health permit a comprehensive view of problems associated with health protection and promotion. This view incorporates an ethical approach to problems both for society and for individuals within the society. Buchanan (2000) captures this necessary synthesis of perspectives well, noting "the mutually reinforcing relationships among justice, caring and responsibility" which will help nurses to "enable people to live well."

Strategies for Ethical Decision-Making

Locating the Source and Levels of Ethical Problems

Most health-promotion problems are moral or ethical issues in the sense that obstacles exist that prevent an individual from living life well or achieving personal goals related to health. Throughout this chapter, discussions of both the larger (societal) and the narrower (individual) perspectives have been emphasized and their relationships highlighted. Sometimes tensions between the two require mediation and may force the health promoter to decide which problem must be addressed first. For example, a nurse at a family practice clinic cares for a teenager who is morbidly obese. At the level of the individual, the nurse is charged with discovering the underlying causes of the obesity (e.g., physical, psychological, contextual) and designing strategies with the individual to help resolve the problem. However, the nurse has responsibilities also to address the issue at the more political level with interested others.

To address health-promotion issues effectively, professionals need to possess not only their particular disciplinary expertise and an understanding of ethical language, principles, and perspectives, but also a willingness to understand their own values and preconceptions about health and people. Understanding personal philosophy, biases, and values permits one to control for these in the sense of being aware of the influences they have in our interactions with others.

Values Clarification and Reflection

Gaining confidence in moral decision-making is a slow process. The following are suggestions that will guide development related to recognizing and addressing ethical issues.

Examine Beliefs and Values

Cultivate the habit of examining how your personal values and **beliefs** relate to the human condition, justice, and responsibility. Be willing to revise your beliefs in line with your professional knowledge base, experiences, or current research findings. For example, how do beliefs that "people get what they deserve" correlate with what we know—for example, that those of lower socioeconomic status have lower levels of health and that poor health interferes with functioning and is associated with depression? How do our attitudes change when we try to place ourselves in the context of the other person's life?

This is not to say that maintaining personal integrity is not important—it is. Maintaining both personal and professional integrity is essential to good practice. Integrity has to do with a sense of wholeness of the self and consistency of actions with truly examined beliefs and values. "Nurses have both personal and professional identities that are integrated and that embrace the values of the profession, merging them with personal values" (ANA, 2015). The *Code of Ethics for Nurses with Interpretive Statements* validates the nurse's preservation of integrity in those situations in which he or she feels that personal integrity is compromised. It notes that "when a particular decision or action is morally objectionable to the nurse,… the nurse is justified in refusing to participate on moral grounds" (ANA, 2015). In contemplating refusal to provide care, however, the nurse should ensure that the decision is based on sound ethical principles, not simply on personal beliefs. When opting out of care involves risk to the individual, other arrangements must be made to safeguard individual care. Decisions not to participate in a situation cannot be made trivially because of the trust relationship and a nurse's moral accountability for actions. The threat to the nurse's integrity must be serious and the person's well-being must not be jeopardized by the nurse's absence. Other arrangements must be made for care of the person in such circumstances. The nurse who encounters repeated threats to integrity has a responsibility to consider changing the situation in some way. Change efforts may be directed toward institutional policy or may require that an alternative work environment be considered.

A true examination of beliefs and values requires a willingness to admit that they may not always be justifiable; they may be remnants from childhood indoctrination of various sorts. For example, one might believe that certain ethnic groups are inferior in some way, or that one should not question authority. An honest and ongoing examination of one's values and biases permits one to control for these beliefs when providing care to diverse persons. Being willing to examine one's beliefs and values—being willing to continue that upward journey out of Plato's cave—is thus a key part of personal and professional integrity.

The Influence of Personal Beliefs and Values

In addition to examining beliefs and values, we should also think about the influence that these characteristics have on our practice. An understanding of how personal beliefs and values either are congruent or are liable to interfere with the task at hand is crucial to ethical problem-solving. In any given situation, the health professional must ask himself or herself, "What are my beliefs and biases in this situation? How are these likely to influence my actions?" For example, if the home health nurse believes his below-poverty-level, depressed, obese, diabetic patient who smokes is responsible for the poor healing of her leg ulcer, he may be less inclined to work with the person to discover and address the person's goals.

Reflection on Practice

A third helpful strategy is to reflect on situations afterward to discover what worked, what did not work, and what could be done differently in the future. It is often helpful to interact with peers or other experts after particularly difficult situations to discover alternative perspectives or resources for the purposes of future problem-solving. You might ask a peer or mentor to ask you questions to help you think through why you made a particular decision. Or you might practice some reflective writing to help you think through your reasoning and consider whether you would act differently in the

future (Dinkins, 2015).

Decision-Making Considerations

Decision-making in health-promotion settings has inescapable moral components. As noted earlier, the nurse has a professional responsibility to further the good for individuals and society. Thus the careful exercise of experience, skill, and knowledge is warranted when one is trying to formulate the best course of action for a given individual or group, or in resolving societal health-promotion problems. This framework is offered as a way of ensuring clarity about a particular case or situation. Because of the diverse nature of health-promotion activities, no straightforward models of decision-making can realistically be applied in all situations. Additionally, decision-making is often an ongoing process, and revisions to plans may be required in light of new information. The following are important facets of decision-making but do not necessarily occur in the order given.

Identify the Main Problem or Issue

What level of problem is this: social, group, or individual? If the location of the problem is societal, it will also impact individuals and groups, and a decision has to be made about the order of interventions. Try to determine the main ethical principle involved or whether it is a problem of conflicting principles. For example, after identification of the problem, you may determine that to provide benefit to the person, the person's autonomy must be overridden. Is this a social justice issue? Is it an autonomy issue? What factors led to the problem? Is there coercion or other power imbalance? If so, who has an interest in maintaining the power imbalance and who gains the most from the imbalance? These are the questions feminist ethics would ask.

Determine on Whom the Resolution Will Have an

Impact

Who has a stake in the issue and in how it will be resolved? Answering this question will permit a determination of whose input is crucial to the decision-making process. Who and what are important considerations (e.g., institutions, individuals, businesses, social policy)? Does this issue result from a failure to predict the consequences of certain social policies?

Determine the Prevalent Values

What are the values held by all the different players? Are there value conflicts? The value conflicts might be individual versus social, as in the case of a person with tuberculosis who refuses to take his medicines, thus putting at risk members of his family or members of the community. Value conflicts might also be interpersonal among the health-promotion team or they might be personal versus professional. As a general rule, more weight is assigned to the values of the individual who is most likely to be affected by a decision. It is important to consider the influence of culture on values when the issue involves health promotion for culturally diverse groups. It is also important to involve people who can help explain the cultural beliefs, especially when language difficulties are present. A knowledgeable but neutral interpreter may be helpful when liaison between groups is needed.

Identify Information Gaps

Reflect on whether the decision makers are confident about what they know and do not know, and what they may be overlooking. This determination is not always an easy task. Information may exist that has not yet reached our awareness, or we might fail to ask a question that would reveal important information. How can we be confident about the scope and limits of our knowledge? Clinical judgment is a good tool but is not foolproof. When doubts exist or the decision is likely to have serious or risky consequences, we need to involve knowledgeable others or try to determine the best places to gain

missing information.

Formulate Possible Courses of Action and Probable Consequences

Courses of action may involve further information gathering, brainstorming, and possibly collaboration with other experts or specialists. Although further data may be needed to resolve problems at the level of individuals or small groups, it is especially necessary to enlist additional help when the issue is one that requires political action to effect policy changes. It may be necessary to recruit community members and leaders or to enlist the political power of specialty groups. Finally, a determination must be made about which proposed courses of action will be the least harmful and the most beneficial. Remember not to look just to likely consequences, however. Consider possible actions from the framework of duty and character as well.

Initiate the Selected Course of Action and Evaluate the Outcome

Does the actual outcome match the anticipated outcome? If not, what happened that was unexpected? Would this outcome have been foreseeable given more data? Would you do things differently in another similar situation given what you have learned? Does the problem need to be addressed at a different level (institutional or public policy)?

Engage in Self-Reflection and Peer or Expert Group Reflection

What could you have done differently? Would consulting with others have altered your conception of the problem or your course of action? What insights can you or your peers glean from this that could be appropriate for similar situations in the future? How might continuing education opportunities help you or your peers more

appropriately address similar problems in the future? Would an ethics resource (committee or consultant) be helpful in such situations? Could you use this case as a focused learning experience for your peers and collaborators?

Ethics of Health Promotion: Cases

Some cases of special relevance to health promotion are presented next. They are followed by questions that can be answered by individual readers, but they also provide a good starting point for group discussion. Try using the decision-making strategies suggested throughout the chapter as you explore these problems. It is anticipated that you will want more information than is provided. Deciding what extra information would be helpful is an important part of the exercise.

Case 1: Addressing Health Care System Problems—Elissa Needs Help

Elissa is 38 years old. She recently moved 200 miles from her home to a small town (population 6000) and separated from her abusive husband to escape his continuing threats and to be near her childhood friend. She suffers from chronic, sometimes incapacitating, depression, for which she has received antidepressant medications and counseling, with temporary relief. She has been unable to work and has no private health insurance. She is eligible for the state's Medicaid program, however, and has recently discovered that Medicaid will cover her health care needs. Her friend refers her to the only primary care center in the area, where she is seen by Jill, one of the two nurse practitioners. As part of her evaluation, Jill discovers that Elissa was abused as a child and has very poor self-esteem. Elissa affirms that her childhood friend is very supportive. Jill believes that longer-term psychological counseling would benefit Elissa and facilitate her well-being, but she also knows that none of the counseling services within a 50-mile radius accepts Medicaid payment. Elissa has no transportation.

- What are Jill's options? What are her responsibilities?
- What actions might Jill pursue both on a local level and on a political level? What are her resources?

- What is the responsibility of the health-promotion disciplines in cases such as this?

Case 2: She's My Client!—Lilly and “Jake” (a.k.a. Paul)

Shirley, a nurse practitioner, is at a conference when a physician colleague discusses a difficult case. One of his clients, “Jake,” is HIV positive but refuses any treatment. The physician explains that Jake fears that his wife will discover and recognize the names of the medications, because he knows “these drug names are discussed on television all the time.” Jake has not told his wife that he is HIV positive and has no intention of ever doing so. Jake firmly believes his condition is his private information and, for now, the couple use condoms for birth control. The physician is concerned that Jake will not tell his wife. The physician is presenting this case to colleagues to highlight the public awareness campaigns that, to some extent, have affected client privacy. He argues, “Listen to how they call out your name and the drugs at the pharmacy counter.”

Shirley recognizes bits and pieces of information and comes to the painful realization that Jake is really Paul, and Paul is the husband of one of her clients, Lilly. Lilly has begun to discuss with Shirley that she wants to get pregnant soon. The town is too small for Shirley to be mistaken. Or is it?

- Is it ethical for the nurse practitioner to ask the physician if Jake is Paul?
- Is it ethical for Shirley to tell Lilly she suspects Paul is HIV positive?
- Should this information change how Shirley counsels Lilly about a pregnancy?
- What is in Lilly's best interests? Is Shirley also obligated to consider Paul's interests?
- What resources are available?

Case 3: Don't Touch My Things! Ms. Smyth and

Autonomy

Ms. Smyth, 78 years old, had lived in the same home for 30 years. Never married, she cared for her disabled mother for 15 years. After her mother died, she lived alone on a small pension. She appeared to be well groomed and appropriately dressed when she left her house.

Ms. Smyth was hospitalized for a bowel obstruction, and Joe, a community health nurse, made a follow-up visit after discharge to her home. When Joe arrived at the house, he was overcome with the smell of rotting garbage, urine, and feces. Five small dogs ran back and forth among piles of garbage and magazines, overturned furniture, and discarded appliances. There was no running water, and the bathroom was not functional. Joe told Ms. Smyth that her living conditions were unhealthy and that he would contact a community agency to help her clean her house. Ms. Smyth became very angry and said no one had the right to take her things away.

- Is it ethical for Joe to overrule Ms. Smyth's autonomy in decision-making?
- What action is in Ms. Smyth's best interests?
- What action is in the community's best interests?
- What ethical issues are involved in caring for a client with a hoarding disorder, such as that seen in Ms. Smyth's situation?

Summary

Health promotion is a vast and complex practice area; consequently, the associated ethical challenges are diverse and multileveled. This chapter has outlined the nature and purpose of health care ethics and related this framework to the responsibilities of health care providers in health-promotion interventions. Health promotion should be viewed as a moral undertaking of health care providers. After reading this chapter, students will have knowledge of some of the tools and language needed to explore ethical issues, discuss these issues with others, and address problematic issues at both the individual level and the societal level. Perhaps the most important factor to consider is that ethical problems manifesting themselves at the level of the individual almost always have their origins in the broader societal environment.

Case Study

Genetic Screening Programs

A US company has been sequencing the DNA of 20 individuals. With the individuals' consent, the results will be made available to researchers. Each donor will be offered information about genetic variations that might indicate a higher-than-average likelihood of developing a life-threatening condition.

There are hopes that genetic screenings of large populations will change the practice of health care from a focus on treating diseases to preventing them. Some researchers predict the complete sequencing of each human genome will provide routine data to health care providers, much like the common measurements of blood pressure, pulse, temperature, and blood counts today. Other research data show, however, that better predictors of determining the risk of diabetes are asking people about their family history of diabetes, their weight, and their age rather than sequencing their DNA.

Reflective Questions:

Apply different concepts and theories of ethics in thinking about the following questions.

- What are some of the ethical issues of these DNA analyses?
- What are the responsibilities of health care professionals in the genetic screenings of a population?
- What additional components could a community health nurse add to the following plan of care for participants having their DNA sequenced?

Care Plan

Genetic Screening Programs

The use of developments in genetics research, including genetic counseling, testing, and screening, as well as advanced therapeutic and reproduction choices, influences the health of both present and future generations throughout the world.

As previously addressed, health care professionals have many complex ethical responsibilities in the applications of genetic developments with local, national, and international communities, as well as with individuals and families.

In the following care plan, the community health nurse from the preceding case study addresses aspects of the ineffective management of genetic screenings in a community.

***NURSING DIAGNOSIS: Ineffective community therapeutic regimen management**

Definition

Pattern in which a community experiences (or is at risk of experiencing) difficulty integrating a genetic screening program for the prevention/treatment of illness and reduction of risk

Defining Characteristics

Major: Community verbalizes desire to manage the genetic screenings and treatment of illness and prevention of sequelae; community verbalizes difficulty with regulation and integration of prescribed regimens for genetic screening and treatment of illness and its effects or prevention of complications.

Minor: Knowledge of risk factors for illness (expected or unexpected) is accelerated.

Related Factors

Treatment Related

- Complexity of genetic screening and therapeutic regimen
- Complexity of health care
- Financial costs
- Actual cost of procedure
- Potential cost (e.g., loss of health insurance)
- Side effects
- Expected (e.g., anxiety)
- Unexpected (e.g., despair)

Situation/Environment Related

- Health and health care needs, multiple and complex, especially for vulnerable population (e.g., unborn children)
- Presence of known and unknown environmental (including occupational) health hazards
- Availability of community resources for screening for risk factors of diseases
- Less expensive (e.g., family health histories and physical exams); more expensive (e.g., genetic screenings)
- Overall needs and financial resources

Expected Outcomes

With the community health nurses' guidance, community members will:

- Evaluate the actual and potential (e.g., significant increases in birth rates) health problems and resources of the community.
- Identify community resources that are needed to promote health and prevent illness, including genetic screenings.
- Participate in program development as needed to improve the effectiveness of the therapeutic regimen management of genetic screening programs.

Interventions

- Complete a community assessment including:

- Actual and potential health problems and needs
- Actual and potential resources for health
- Develop an overall program plan for genetic screenings
- Develop a specific program for the genetic screening of an individual, perhaps including the following components:
- Complete initial interview, individual and family histories, and physical examination with appropriate laboratory studies
- Generally, discuss the genetic screenings and informed consent, focusing on the concerns of the individual and/or family
- Assess barriers to learning:
- Physical condition
- Sensory status (e.g., vision, hearing)
- Intelligence, learning abilities/disabilities
- Emotional state(s) (e.g., fears, guilt)
- Stressors, concerns
- Provide information:

- Explain needed knowledge and perhaps changes (e.g., lifestyle behaviors)
- Discuss and add to individual's knowledge of the pros and cons of genetic screening
- Identify influencing factors to decision-making about individual's genetic screening
- Perform screenings (e.g., depression, financial resources).
- Give time to integrate new information, perhaps having a second appointment to:
- Readdress questions
- Develop informed consent, including policies on privacy
- Perform actual genetic screening procedure.
- Explain results with genetic and reproductive counseling.
- Repeat and follow up as necessary.
- Compare the diagnostic criteria for Ineffective Therapeutic Regimen Management with other differential diagnoses potentially present in the case study.

UNIT 2
Assessment for Health Promotion

OUTLINE

6 Health Promotion and the Individual
7 Health Promotion and the Family
8 Health Promotion and the Community

Health Promotion and the Individual

Anne Rath Rentfro

OBJECTIVES

After completing this chapter, the reader will be able to:

- Define the framework of functional health patterns as described by Gordon (2016).
- Describe the use of the functional health pattern framework to assess individuals throughout the life span.
- Illustrate health patterns of the functional, potentially dysfunctional, and actually dysfunctional categories of behavior.
- Identify risk factors or etiological aspects of actual or potential dysfunctional health patterns to consider with nursing diagnoses.
- Discuss the planning, implementation, and evaluation of nursing interventions to promote the health of individuals.
- Develop specific health-promotion plans based on an assessment of individuals.

KEY TERMS

Age-developmental focus

Culturally competent care

Cultural attunement

Risk factors

Think About It

Assessment of Alcohol Consumption

Women have different patterns of alcohol consumption and different thresholds for problem drinking than men. Instruments such as the CAGE questionnaire detect alcohol dependence and would not be a sensitive enough measure for some women, in particular pregnant women, who are less likely than men to be alcohol dependent. The T-ACE instrument provides a measure of alcohol intake patterns more appropriate for women than that derived from the CAGE test (considered Cutting *down on drinking, been* Annoyed *by criticism of drinking, feeling* Guilty *about drinking, and using alcohol as an* Eye-*opener). The T-ACE test, developed for use with women, was the first validated screening tool for assessing drinking risk in pregnant women and continues to provide a highly sensitive tool for identifying risk drinking (Bax et al., 2015). Screening is a useful strategy in health-promotion assessment and intervention (see Chapter 9). A pattern of drinking is established with use of the following questions:*

T—*How many drinks does it* Take *to make you feel high?*

A—*Have you ever been* Annoyed *by people criticizing your drinking?*

C—*Have you ever felt you ought to* Cut *down your drinking?*

E—*Have you ever had a drink first thing in the morning* (Eye-*opener) to steady your nerves or get rid of a hangover?*

Scores are calculated as follows:

- A reply of more than two drinks to question T is considered a positive response and scores 2 points, and an affirmative answer to question A, C, or E scores 1 point respectively.
- A total score of 2 or more points on the T-ACE indicates evidence of risk drinking.

Why would a nurse tailor the assessments to individual characteristics of a population? How effectively would this screening tool identify alcohol problems in women other than the pregnant women within the population? Why?

In health-promotion practice, nurses assess patterns and use their assessment to facilitate individuals' maintenance of well-being or their progression toward wellness. Health and illness within this context reflect changing patterns of the life process. For example, generally when disorganization or ineffective coping produce fluctuations in patterns that eventually result in illness, a treatment plan is designed to alleviate the symptoms or eliminate the illness altogether. The strategies used in this assessment process focus on identifying abnormalities. Conversely, health promotion aims to maintain effective coping strategies to prevent illness in the first place, therefore requiring different approaches to assessment and planning. One foundational concept in health promotion is strength or asset assessment. Using patterns of strength, according to Newman's theory of health as expanding consciousness, nurses should redirect the individual toward more harmonious patterns of health promotion (Bateman & Merryfeather, 2014). In practice the framework of holistic nursing is congruent with Newman's theory. Holistic nursing provides central unifying themes that connect pattern recognition to person-environment relationships for health promotion throughout

the lifespan. Holism emerges from each of the holistic nursing core values of philosophy, caring process, communication, attunement, healing, cultural diversity, education, research, self-reflection, and self-caring (Dossey et al., 2016).

In the United States, *Healthy People 2020*, the national health-promotion initiative, establishes national goals and provides a framework for prevention (US Department of Health and Human Services, 2015). *Healthy People 2020* publishes national health objectives that identify the most significant preventable threats to health. Communities use these objectives and associated indicators to evaluate progress toward the overall goals of attaining high-quality longer lives, decreasing health disparity, and creating environments that promote health and improve the quality of life for all (US Department of Health and Human Services, 2015). *Healthy People 2020* added the following topics that were not part of the *Healthy People 2010* initiative:

- Adolescent health
- Blood disorders and blood safety
- Dementias, including Alzheimer disease
- Early and middle childhood
- Genomics
- Global health
- Health care–associated infections
- Health-related quality of life and well-being
- Lesbian, gay, bisexual, and transgender health
- Older adults
- Preparedness
- Sleep health
- Social determinants of health

Most of these new topics concern primary prevention for individuals in some way. Selected examples of how the *Healthy People 2020* (USDHHS, 2015) objectives address these primary prevention

areas for individuals are presented in Box 6-1: *Healthy People 2020*. Furthermore, this initiative maintains current data to be used to evaluate regional efforts toward the national goals and for the nation to progress to a healthier status.

Box 6-1

Healthy People 2020

Selected Examples of National Health-Promotion and Disease-Prevention Objectives for Individuals From *Healthy People 2020*

- **H-1** Increase the proportion of adolescents who have had a wellness checkup in the past 12 months
- **AH-3.1** Increase the proportion of adolescents who have an adult in their lives with whom they can talk about serious problems
- **AOCBC-10** Reduce the proportion of adults with osteoporosis
- **EMC-2** Increase the proportion of parents who use positive parenting and communicate with their physicians or other health care professionals about positive parenting
- **SDOH-1** Increase the proportion of children aged 0 to 17 years living with at least one parent employed year-round, full-time
- **NWS-13** Reduce household food insecurity and in doing so reduce hunger
- **SH-2** Reduce the rate of vehicular crashes per 100 million miles traveled that are due to drowsy driving
- **SH-3** Increase the proportion of students in grades 9 through 12 who get sufficient sleep

- **SH-4** Increase the proportion of adults who get sufficient sleep
- **BDBS-1** (Developmental) Increase the proportion of persons with hemoglobinopathies who receive recommended vaccinations
- **BDBS-6** (Developmental) Increase the proportion of children with sickle cell disease who receive penicillin prophylaxis from 4 months to 5 years of age
- **G-1** Increase the proportion of women with a family history of breast and/or ovarian cancer who receive genetic counseling
- **G-2** (Developmental) Increase the proportion of persons with newly diagnosed colorectal cancer who receive genetic testing to identify Lynch syndrome (or familial colorectal cancer syndromes)
- **IID-1** Reduce, eliminate, or maintain elimination of cases of vaccine-preventable diseases
- **OA-2** Increase the proportion of older adults who are up to date on a core set of clinical preventive services
- **AHS-1** Increase the proportion of persons with health insurance

From US Department of Health and Human Services. (2015). *2020 topics and objectives.* http://www.healthypeople.gov/2020/topics-objectives.

Long before this current focus on health promotion with the *Healthy People* initiatives in the United States, nursing theorists, such as Newman, Rogers, and Pharris, posited that nurses care for well individuals, as well as those who are ill (Bateman & Merryfeather, 2014). The International Council of Nurses (2015) defines nursing as encompassing the "autonomous and collaborative care of individuals of all ages, families, groups and communities, sick or well and in all settings. Nursing includes the promotion of health, prevention of illness, and the care of ill, disabled and dying people. Advocacy, promotion of a safe environment, research, participation in shaping

health policy and in client centered care, health systems management, and education are also key nursing roles." This broad definition provides a foundation for nursing globally using the nursing process: assessment, diagnosis, outcome criteria, process criteria (including planned interventions), implementation, and evaluation. The nursing process, in turn, establishes a useful framework for the health-promotion assessment of the individual.

Nurses typically use assessment strategies including health promotion that address interactions among an individual's biophysical, psychosocial, and spiritual states and patterns with the environment. When assessing for primary prevention, the techniques also include generalized health promotion and specific protection from disease, both of which fall within the scope of nursing practice. The active process of promoting health involves protection (immunizations, occupational safety, and environmental control) along with lifestyle, value, and belief system behaviors that enhance health.

With health promotion serving as the underlying theme, this chapter addresses nursing assessment of individuals. In most areas of health care, tertiary care and prevention of further disease provide the assessment focus (Hopkins & Rippon, 2015). This tertiary care–focused assessment identifies deficits, thus excluding assessment of overall general health and wellness. Most nursing diagnoses approved by NANDA International (formerly the North American Nursing Diagnosis Association) are problem oriented. The NANDA International definition of **nursing diagnosis** includes life processes, as well as actual or potential health problems. One way to address nursing diagnoses in well individuals is to focus on human developmental or maturational tasks. Most approved nursing diagnoses reflect a focus on deficit assessment and problem-solving; however, these diagnoses include many life processes that provide the broad base needed for nursing to address strength-based healthy responses or potential for healthy responses (Paans et al., 2013). Furthermore, concentrating on strengths in the health-promotion setting provides a foundation to help individuals move toward

improved health. Nurses support and enhance the ability of healthy individuals to maintain or strengthen their health.

Current US health care systems continue to use deficit assessment rather than the asset-based approach that is more appropriate for health-promotion settings. Mental health, social work, and nursing, however, embrace an asset-based approach to assessment within the health-promotion context. From using infant competencies to plan care and person-centered approaches for care of people with mental health disorders, nurses incorporate asset-based assessment into their diagnostic process (de Moura Quintana et al., 2014; Hopkins & Rippon, 2015; Thomé et al., 2014). Although NANDA International has stated that there is a need for work in this area of asset-based assessment and wellness, published material for using wellness diagnoses appears infrequently. The NANDA International taxonomy, however, uses multiple dimensions of human response in the consideration of each diagnosis. These seven dimensions include the status of the diagnosis that considers whether the diagnosis is addressing wellness, risk, or an actual problem (Gordon, 2016). More work is necessary to develop and promote useful language for health-promotion and wellness diagnoses.

Gordon's (2016) framework, which uses a **functional health patterns** assessment, provides the foundation for the construction of the NANDA International nursing diagnosis nomenclature. As NANDA International continues to develop diagnoses for health promotion, Gordon's framework will most likely continue to provide the foundation for these diagnoses. This same framework is used throughout this chapter to demonstrate assessment approaches, as well as family and community assessment (see Chapters 7 and 8). In addition, this chapter presents components of the nursing process as they relate to health promotion of the individual.

Gordon's Functional Health Patterns: Assessment of the Individual

Nursing assessment determines the **health status** of individuals. Table 6-1 demonstrates aspects of a complete nursing assessment. Assessment, in this case, refers to collection of data that culminates in problem identification or a diagnostic statement. Effective health assessment considers not only physiological parameters but also how the human being interacts with the whole environment. Behavior patterns, beliefs, perceptions, and values form the essential components of health assessment when nurses consider the maximal health potential of the individual. Pattern recognition supports our understanding of health of individuals and is reflected in nursing theories such as those initially developed by nursing theorists such as Newman (Bateman & Merryfeather, 2014).

TABLE 6-1

Aspects of a Nursing Assessment

Definition	**Deliberate and Systematic Data Collection**
Components	Subjective data: Health history, including subjective reports and individual perceptions
	Objective data: Observations of nurse Physical examination findings Information from health record Results of clinical testing
Function	Description of person's health status
Structure	Organization of interdependent parts describing health, function, or patterns of behavior that reflect the whole individual and environment
Process	Interview, observation, and examination
Format	Systematic but flexible; individualized to each person, nurse, and situation
Goal	Nursing diagnosis or problem identification Identification of areas of strengths, limitations, alterations, responses to alterations and therapies, and risks

Historically, conceptual models in nursing have used Gordon's health-related behaviors particularly in regard to formulating a framework to guide assessment. The current expansion of electronic

documentation from acute care to ambulatory settings requires continued emphasis on the standardization of language. (Doenges et al., 2013). Gordon's 11 functional health patterns interact to depict an individual's lifestyle. Using this framework, nurses combine assessment skills with subjective and objective data to construct patterns reflective of lifestyles.

Functional Health Pattern Framework

Holism and the totality of the person's interactions with the environment form the philosophical foundations of Gordon's functional health patterns. This foundation provides a context for collecting data that provide information about the entire person and most life processes. By examining functional patterns and interactions among patterns, nurses accurately determine and diagnose actual or potential problems, intervene more effectively, and facilitate movement toward outcomes to promote health and well-being (Gordon, 2016). In addition to providing a framework to assess individuals, families, and communities holistically, functional health patterns provide a strong focus for more effective **nursing interventions** and outcomes. This stronger focus provides a solid position from which nurses participate as decision makers in health care systems at organizational, community, national, and international levels.

Definition

Functional health patterns view the individual as a whole being using interrelated behavioral areas. The typology of 11 patterns serves as a useful tool to collect and organize assessment data and to create a structure for validation and communication among health care providers. Each pattern described in Table 6-2 forms part of the biopsychosocial-spiritual expression of the whole person. Individual reports and nursing observations provide data to differentiate patterns. As a framework for assessment, functional health patterns provide an effective means for nurses to perceive and record complex

interactions of individuals' biophysical state, psychological makeup, and environmental relationships.

TABLE 6-2

Typology of 11 Functional Health Patterns

Pattern	Description
Health perception–health management pattern	Individual's perceived health and well-being and how health is managed
Nutritional-metabolic pattern	Food and fluid consumption relative to metabolic needs and indicators of local nutrient supply
Elimination pattern	Excretory function (bowel, bladder, and skin)
Activity-exercise pattern	Exercise, activity, leisure, and recreation
Sleep-rest pattern	Sleep, rest, and relaxation
Cognitive-perceptual pattern	Sensory, perceptual, and cognitive patterns
Self-perception–self-concept pattern	Self-concept pattern and perceptions of self (body comfort, body image, and feeling state); self-conception and self-esteem
Roles-relationships pattern	Role engagements and relationships
Sexuality-reproductive pattern	Person's satisfaction and dissatisfaction with sexuality and reproduction
Coping-stress tolerance pattern	General coping pattern and effectiveness in stress tolerance
Values-beliefs pattern	Values, beliefs (including spiritual), or goals that guide choices or decisions

Modified from Gordon, M. (2016). *Manual of nursing diagnosis* (13th ed.). Sudbury, MA: Jones & Bartlett.

Characteristics

Functional health patterns are characterized by their focus. Gordon (2016) uses five areas of focus: pattern, individual-environmental, age-developmental, functional, and cultural.

Pattern focus implies that the nurse explores patterns or sequences of behavior over time. Gordon's term *behavior* encompasses all forms of human behavior, including biophysical, psychological, and sociological elements. Pattern recognition, a cognitive process, occurs during information collection. Cues are identified and clustered while information is being gathered. Patterns emerge that represent historical and current behavior. Quantitative patterns such as blood pressure are readily identified, and pattern recognition is facilitated when baseline data are available. As the nurse incorporates a broader range of data, patterns imbedded within other patterns begin to

emerge. Blood pressure, for example, is a pattern within both the activity pattern and the exercise pattern. Individual baseline and subsequent readings may present a pattern within expected norms. Erratic blood pressure measurements indicate an absence of pattern. Functional health pattern categories provide structures to analyze factors within a category (blood pressure: activity pattern) and to search for causal explanations, usually outside the category (excessive sodium intake: nutritional pattern) (Gordon, 2016).

The **individual-environmental focus** of Gordon's framework (2016) refers to environmental influences occurring within many of the patterns. For example, environmental influences in the functional health pattern include role relationships, family values, and societal mores. Personal preference, knowledge of food preparation, and ability to consume and retain food govern the individual's intake. Cultural and family habits, financial ability to secure food, and crop availability also influence food intake. Additionally, the person who secures, prepares, and serves the food controls the nutritional intake for the family. Individuals' internal and external environments influence the health patterns in multiple ways.

Each pattern also reflects a human growth and **age-developmental focus** (Gordon, 2016). As individuals fulfill developmental tasks, complexity increases. These tasks, however, provide learning opportunities for individuals to maintain and improve their health. Erikson's framework, which organizes specific health tasks for individuals to accomplish at each developmental phase of the life cycle, continues to serve as a framework to assess and plan care (Kramp, 2014). Erikson's eight stages provide the traditional developmental assessment nurses generally use to plan care (Table 6-3). Each stage presents a central task or crisis that must be resolved before healthy growth can continue (Erikson, 1963). Individuals develop their sense of autonomy in early childhood and struggle with the sense of shame and doubt. When this developmental level is achieved or resolved, the child moves on to develop initiative during the next stage.

TABLE 6-3

Relationship Between Selected Developmental Tasks and Wellness Tasks for Each Stage of the Life Cycle

Erikson's Eight Life Stages	Havighurst's Developmental Tasks	Examples of Minimal Wellness Tasks for Each Developmental Stage
1. Infancy (trust vs. basic mistrust)	Learning to walk Learning to take solid foods Learning to talk Learning to control elimination of body waste	Acquiring ability to perform psychomotor skills Learning functional definition of health Learning social and emotional responsiveness to others and to the physical environment
2. Early childhood (autonomy vs. shame and doubt)	Learning gender difference and sexual modesty Achieving physiological stability Forming simple concepts of social-physical reality Learning to relate emotionally to parents, siblings, and others Learning to distinguish right from wrong and developing a conscience Learning physical skills necessary for ordinary games	Learning about proper foods, exercise, and sleep Learning dental hygiene Learning injury prevention (safety belts and helmets, sunscreen, smoke detectors, poisons, firearms, and swimming) Refining psychomotor and cognitive skills
3. Late childhood (initiative vs. guilt)	Building wholesome attitudes toward self as a growing organism Learning to get along with peers	Developing self-concept Learning attitudes of competition and cooperation with others Learning social, ethical, and moral differences and responsibilities
4. Early adolescence (industry vs. inferiority)	Learning appropriate gender identity: masculine or feminine role Developing fundamental skills in reading, writing, and calculating Developing concepts necessary for everyday living Developing conscience, morality, and scale of values Achieving personal independence Developing attitudes toward social groups and institutions	Learning that health is an important value Learning self-regulation of physiological needs—sleep, rest, food, drink, and exercise Learning risk taking and its consequences (injury prevention)
5. Adolescence	Achieving new and	Learning economic responsibility

(identity vs. role confusion)	maturer relations with peers and both genders Achieving gender identity Accepting physique and using body effectively Achieving emotional independence of parents and other adults Achieving assurance of economic independence Selecting and preparing for occupation Preparing for marriage and family life Developing intellectual skills and concepts necessary for civic competence Desiring and achieving socially responsible behavior	Learning social responsibility for self and others (preventing pregnancy and sexually transmitted diseases) Experiencing social, emotional, and ethical commitments to others Accepting self and physical development Reconciling discrepancies between personal health concepts and observed health behaviors of others (use of alcohol, drugs, tobacco, firearms, and violence) Learning to cope with life events and problems (suicide prevention) Considering life goals and career plans and acquiring necessary skills to reach goals Learning importance of time to self and world
6. Early adulthood (intimacy vs. isolation)	Selecting and learning to live with a mate Starting a family; managing a home Taking on civic responsibility	Committing to mate and family responsibilities Selecting a career Incorporating health habits into lifestyle
7. Middle adulthood (generativity vs. stagnation)	Accepting and adjusting to physiological changes Achieving adult social responsibility Maintaining economic standard of living Assisting adolescent children	Accepting aging of self and others Coping with societal pressures Recognizing importance of good health habits Reassessing life goals periodically
8. Maturity (ego integrity vs. despair)	Adjusting to decreasing physical strength and health Adjusting to retirement and reduced income Adjusting to death of spouse/life partner Establishing an explicit affiliation with own age group Establishing satisfactory physical living arrangements	Becoming aware of risks to health and adjusting lifestyle and habits to cope with risks Adjusting to loss of job, income, and family and friends through death Redefining self-concept Adjusting to changes in personal time and new physical environment Adjusting previous health habits to current physical and mental capabilities

Both age and developmental stage continue to provide the foundation for contemporary assessment of individuals' health status. Developmental tasks begin at birth and continue until death. By considering current epidemiological data and recommended health behaviors, Gordon's (2016) framework continues to be useful today for health promotion throughout the life span. Therefore in Unit 4 Gordon's framework is used to explore developmental tasks and their related health behaviors for health promotion.

Functional focus refers to an individual's performance level. Other disciplines plan care using functional patterns, but assessment data differ among disciplines (Stallinga et al., 2014). Physical therapists and occupational therapists, for example, focus on physical ability to perform activities of daily living and rely on assessments of independent ability to perform personal activities of daily living to develop their plans. For physicians, genitourinary function refers to frequency or voiding patterns and characteristics of urine, such as color, odor, and laboratory analysis results. In addition to these factors of genitourinary function, nurses assess how the particular voiding pattern affects lifestyle, particularly how urinary frequency affects sleep patterns and the ability to perform activities such as shopping or socializing. Additional concerns might include the individual's ability to walk or climb stairs to the bathroom or to manage these activities safely at night. It has been suggested that all health disciplines should use the *International Classification of Functioning, Disability and Health*. Relying on this classification could promote transdisciplinary communication about functional patterns when used along with the NANDA International taxonomy (Stallinga et al., 2014).

Culture, age, and developmental and gender norms, considered during assessment, influence development of health patterns. Leininger defines transcultural nursing concepts of cultural care,

health, well-being, and illness patterns in different environmental contexts and under different living conditions (Gordon, 2016). **Culturally competent care** is delivered with knowledge of and sensitivity to cultural factors influencing health behavior. Complex cultural patterns transmitted from former generations contribute to individuals' health behavior. Culturally competent care respects the underlying personal and cultural reality of individuals. Given that one may never be fully competent in cultures other than one's own culture, the term **cultural attunement** may be more descriptive of the aim. Nurses provide more culturally attuned care when they use cultural norms, values, communication, and time patterns in reflective practice (Andrews & Boyle, 2015). The nurse and the individual interact, and the nurse reflects on the interaction and resumes interaction, making changes on the basis of the self-reflection. For example, when one is tuning a piano, the pitch from the piano and that from the tuning fork must match. The tuning continues until the two sounds resonate. When individuals and nurses experience emotional and physiological resonance surrounding individuals' sociocultural contexts, such as race, ethnicity, religion, and sexual orientation, they resonate and achieve attunement (Pandit et al., 2014).

The concept of attunement is particularly valuable when nurses are caring for people of multiple cultures, such as in an urban setting (Niño et al., 2016). Even when the individual and the nurse share ethnic or racial backgrounds, their particular heritage may be quite different. For example, many different ethnic groups speak Spanish from different countries or provinces within a country (Spain, Mexico, Puerto Rico, Cuba, Columbia, etc.) but may have different colloquialisms within their speech and different cultural values and norms. A Spanish-speaking nurse of Mexican heritage may not be culturally competent in caring for a client from Spain. Asian clients will also have diverse languages and cultural values. Cultural attunement may be useful in these kinds of settings.

Functional health patterns form a framework that centers on health and can account for cultural factors. Most nursing assessments use functional pattern assessment as a foundation to their practice.

Although nursing theoretical and conceptual frameworks differ, the functional health pattern framework is relevant to most conceptual models. In fact, functional health patterns provide the structure used by NANDA International to support nursing diagnosis nomenclature. Nursing classification of interventions and outcome nomenclature also use Gordon's functional patterns as a foundation (Gordon, 2016). The advantages of a functional health pattern framework specific to the practice of nursing include the following:

- It provides consistent nursing language through collecting, organizing, presenting, and analyzing data to determine nursing diagnoses.
- It allows flexibility to tailor content for individuals and situations.
- It suits diverse practice areas (e.g., home, clinic, institution) for assessment of individuals (adult/children), families, or communities.
- It supports theoretical components of nursing service, education, and research by organizing clinical knowledge using nursing diagnoses, interventions, and outcomes.
- It incorporates medical science data while retaining the focus on nursing knowledge and practice.

The Patterns

Each pattern reflects a biopsychosocial spiritual expression of the individual's lifestyle or life processes from the perspective of both the individual and the nurse. This expression reveals the following elements: a pattern or sequencing of behaviors; the role of the environment (physical surroundings, family, societal, and cultural influences); and developmental influences. The assessment of each pattern includes its status as functional (strengths/wellness), dysfunctional (actual), or potentially dysfunctional (risk), as well as an indication of the individual's level of satisfaction with the pattern (Gordon, 2016). Nurses continue assessing in more depth to generate an explanation for the problem, to determine remedial actions to take, and to understand the perceived effect of these actions from the individual's perspective. An important goal when assessing each

pattern is to determine the individual's knowledge of health promotion, the ability of the individual to manage health-promoting activities, and the value that the individual ascribes to health promotion with use of an asset-based approach to identify wellness diagnoses. Each pattern is presented in this chapter, with details for nurses to use to assess individuals and determine health-promotion diagnoses using a functional health pattern framework along with a discussion of nursing implications for use of the patterns in health-promotion practice.

Health Perception–Health Management Pattern

The health perception–health management pattern involves individuals' health status and health practices used to reach the current level of health or wellness with a focus on perceived health status and meaning of health (Gordon, 2016). When eliciting this information, nurses discover areas for further exploration under other functional health patterns. For example, if the individual reports shortness of breath when mowing the lawn, the nurse stores this information for later retrieval when he or she is assessing activity and exercise patterns or cognitive-perceptual patterns.

Health perception–health management patterns affect lifestyle and ability to function even when individuals do not perceive actual health problems, are unaware of necessary health promotion in the absence of problems, do not feel capable of managing their health, or believe activity on their part is useless to promote health. Health-promoting activities (e.g., adequate nutrition, activity and exercise, sleep and rest), routine professional examinations, self-examinations, immunizations, and safety precautions (e.g., auto safety restraints and locked medicine cabinets) provide this pattern's clues to maintain optimal quality of life.

Assessment objectives for health perception–health management consist in obtaining data about perceptions, management, and preventive health practices (Gordon, 2016). Exploring values identifies potential health hazards, such as lack of adherence to a prescribed medical or nursing regimen or ability to manage health effectively. In

addition to these kinds of assessment cues, nurses identify unrealistic health and illness perceptions and expectations. The transtheoretical model consists of five stages that can be useful in assessing an individual's readiness to change (see Chapter 10). These stages—precontemplation, contemplation, planning/preparation, action, and maintenance—have been used widely in health-promotion programs for diverse populations and multiple age groups with topics ranging from prevention of injury to nutrition-education programs (Doenges et al., 2013).

Assessment includes the following parameters:

- Health and safety practices of the individual
- Previous patterns of adherence or compliance
- Use of the health care system
- Knowledge of health service availability
- Health-seeking behavior patterns
- Means to access health care (e.g., financial resources, health insurance, and transportation)

In addition to methods of health management, nurses explore health perceptions as individuals describe their current health status, past problems, and anticipation of future problems associated with health or health care. These findings reveal beliefs about health, perceived susceptibility, self-efficacy, and level of knowledge of health status, taking into account the influence of culture (Andrews & Boyle, 2015) (Box 6-2: Diversity Awareness). Health and illness perceptions significantly influence overall direction for care planning. Health beliefs, also discussed in the section Values-Beliefs Pattern, directly impact participation in care. Partnership with providers and attunement is also more likely to yield better attention to self-care, particularly in cultures that value collective responsibility. In addition, individuals from cultures valuing collectivism are more likely to engage in self-care measures when their cultural patterns and social support within families are considered (Paek et al., 2014).

Box 6-2

Diversity Awareness

Health Perspectives for Emerging Majority Groups in the United States

Group	TRADITIONAL DEFINITIONS		TRADITIONAL METHODS	
	Health	**Illness**	**Maintain/Protect Health**	**Restore Health**
American Indian and Alaska Native population	Total harmony with nature Survive extremely challenging situations	Price paid for past/future Details specific to nations Results from presence of evil spirits Contagious/generalized symptoms Human body considered as whole, with harmony between origins and superficial structures Integration within context of environment	Maintain positive relationship with nature Treat body with respect Purification acts using water/herbal remedies and rituals	Removal of external causative factor by traditional healer after special ceremony to determine cause Drumming
Asian population	Total physical and spiritual harmony with universe For the majority, religious traditions pose variations on cultural values. Examples include respect for life moderation; basic relationships balance between evil and good	Human body considered as whole with harmony between organs and superficial structures Integration of human body within context of environment Imbalance of yin and yang	Body is gift from parents/ancestors; must be protected Dietary practices Formal daily exercise (tai chi) Amulets (Chinese)	Acupuncture applying poultices Cupping Bleeding Massage Herbal remedies Other products Use physicians Women treat women Use of immunizations Important to keep body intact (Chinese) Amulets
African population	Process/energy force rather than a state Consists of body/mind/spirit harmony with nature Older adults held in high esteem	Harmony; illness attributed to demons and evil spirits Pain as sign of illness; if no pain, then illness is gone	Dietary practices Rest; clean environment Laxatives/cod liver oil taken internally; sulfur and molasses on back Protective material of various substances (copper/silver/dried flesh); prayer	Voodoo and magic Care for the entire community Prayer Use of healers Pictures—Catholic saints/relics Sugar and turpentine

				herbs, minerals, oral preparations, including hot water and lemon garlic, flannel with camphorated oil
Hispanic population	Gift from God	Imbalance in body; punishment for wrongdoing Imbalance between hot and cold/wet and dry (definitions differ) Dislocation of body parts Magic or supernatural causes such as evil	Maintain equilibrium in universe through behavior, diet, and work	Prayer, dietary practices of hot/cold magic/religious rituals, artifacts Frequently in Catholic and Pentecostal traditions such as offerings, confession, candles, laying on of hands Folk holistic healers using herbs, prayer, massage, social rapport, spiritual healing

There is wide diversity among racial and ethnic groups. Cultural beliefs and language may be quite different from one group to another within the same race or ethnicity. For more information about these concepts see Richeson, J. A., & Sommers, S. R. (2016). Toward a social psychology of race and race relations for the twenty-first century. *Annual Review of Psychology*, *67*, 439–463.

It is also important to assess health management practices. In a study about the influence of past health management practices on future health management in posttraumatic brain injury patients, Ulfarsson and colleagues (2014) demonstrated that past health management practices such as use of sick time and employment status influenced their posttraumatic brain injury health management. This study provides some support for the belief that if adherence to a prescribed regimen has not occurred in the past, future adherence is also unlikely. Nurses aim to identify and remedy the causes of the discrepancies between provider recommendations and the individual's implementation of those recommendations. For example,

an individual with high blood pressure who has failed to keep follow-up appointments, not taken medication as prescribed, and eaten foods with high sodium content should be assessed to determine whether this evident nonadherence results from a conflict within the value system of the individual (health beliefs); inaccurate information; misunderstanding; inadequate ability to learn, retain, or retrieve information (knowledge deficit); denial of illness (health perception); or inability to access care and/or resources. Variables such as financial resources, transportation difficulties, nutritional preferences, daily activities (individual and family patterns), ability to read written instructions (literacy or visual acuity), and ability to manipulate numbers (numeracy) may affect the individual's behaviors.

Nutritional-Metabolic Pattern

Nutritional-metabolic patterns center on nutrient intake relative to metabolic need (Gordon, 2016). These patterns include individuals' descriptions of food and fluid consumption (history), as well as evidence of adequate nutrition (physical examination). Nurses explore individuals' satisfaction with current eating and drinking patterns, including restrictions, and their perceptions of problems associated with eating and drinking, growth and development, skin condition, and attunement and healing processes.

Intake and supply of nutrients to tissues and organs influence bodily functions and interact with lifestyle. Sufficient food and fluid intake provides energy for performance, which includes both internal physiological functioning and external body movements. Interruption in acquisition or retention of food or fluids offsets balance and significantly alters lifestyle. In addition to individuals' nutrition and metabolism, genetic variation, specific genetic abnormalities, environmental influences, and prenatal nutrition also govern growth rates (Levitsky, 2016).

Assessment within this pattern includes data about typical patterns of food and fluid consumption and adequacy of consumption patterns, along with perceived problems associated with nutritional intake. Nurses attend to cues to conditions of overweight,

underweight, overhydration, dehydration, or difficulties in skin integrity, such as breakdown or delayed healing. Individuals may also be at risk of developing these problems. Conversely, this pattern may exhibit assets or strengths that can be used to support the health-promotion plan.

The parameters for assessment for this pattern fall into two broad categories of evaluation: nutrient intake and metabolic demand. Intake may be assessed with a 24-hour recall of food and fluid consumption; a listing of dietary restrictions, food allergies, vitamin supplements, and caffeine and alcohol ingestion (when not included in the medication history); and a schedule of eating and drinking patterns. Assessment includes screening individuals for problems associated with swallowing or chewing.

With identified problems, focused assessments include food preferences, feelings about present weight, and eating habits. Intake may be affected when individuals eat alone. Frequent dining out may indicate the need for further exploration within the nutrition area or other functional patterns. Fast food consumption may be the predominant source of nutrients. Consumption patterns may be deficient in essential vitamins or minerals. Food security may also be explored. Who purchases food? Is shopping preplanned with a grocery list? Are financial resources and food budgets adequate? Is food stored properly? Who prepares food? How is food prepared (fried, broiled, steamed, boiled, or baked)?

Metabolic demands differ from individual to individual and vary within the same individual during times of illness, stress, growth, high- or low-activity levels, healing, or recovery. Developmental and environmental conditions alter metabolic demands. Appetite and reported changes in weight, skin integrity, attunement, and general healing ability are explored during the interview or health history. Individuals may also report decreased tolerances for hot or cold weather.

Nurses' observations and perceptions play a vital role when they are assessing nutritional and metabolic patterns. Physical examination allows assessment of both the nutrient supply to the tissues and the

metabolic needs of the individual. Objective findings serve as indicators to validate subjective reports concerning nutrient intake. Gross metabolic indicators include temperature, height, and weight. Physical examination focuses on skin, bony prominences, dentition, hair, and mucous membranes. Skin and mucous membranes, in particular, use nutrients rapidly and provide excellent indices of nutritional adequacy. Skin assessment includes assessment of color, temperature, and turgor, and evaluation of any skin lesions, areas of dryness, scaliness, rashes, pruritus, or edema. Mucous membranes are examined for color, integrity, moisture, and lesions. Dentition is evaluated for structure. Are teeth erupted at normal stages of development? Are teeth firmly implanted? Do dentures fit properly? Additionally, decay and evidence of oral hygiene are evaluated. Healing is assessed when there is evidence of injury. The assessment may also include laboratory information such as levels of fasting glucose, lipids, blood urea nitrogen, creatinine, calcium, and vitamin D.

Although problem identification occurs after assessment of all 11 functional health patterns, a problem in any one area serves as a clue to dysfunction in others. Assessment of one pattern facilitates synthesis and analysis of data collected in other functional health patterns. Nutrition and metabolism influence patterns of health management, elimination, activity, sleep, cognition, roles, and stress tolerance. The values-beliefs pattern may significantly alter all other functional patterns. Sociocultural values and ethnic backgrounds play a major role in the determination of eating patterns. Other areas to consider include eating habits, food preferences, and patterns of nutrient supply and demand across the life span. Raw fruits and vegetables may be fun “finger food” for the toddler, but the older adult, especially one with loose dentures or arthritis of the temporomandibular joint, may find these foods intolerable. Older adults may also find gastrointestinal intolerances that develop over time and were not present in their youth.

A nutritional pattern focus emphasizes educational needs. Assessment aims to demonstrate strengths in functional patterns

along with disclosing dysfunctional or potentially dysfunctional patterns. Nutritional health-promotion activities present a strength that provides impetus for similar activities in the other patterns. For example, if balanced nutritional intake improves functional level, individuals may extend their health-promoting behaviors to stress reduction or other behaviors. Understanding food/fluid intake and balance of body requirements helps individuals adjust caloric intake as growth slows to prevent overweight problems during the adult years.

Elimination Pattern

Elimination patterns include those related to bowel, bladder, and skin function. Nurses determine regularity, quality, and quantity of stool through subjective reports about methods used to achieve regularity or control and any pattern changes or perceived problems. Perspiration quantity and quality determine excretory skin function (Gordon, 2016).

Elimination pattern significance differs from individual to individual. Many people view elimination patterns as a measure of health and as a sensitive indicator of proper nutrition and stress level. Individuals' perceptions determine whether patterns become problematic or dysfunctional. Misconceptions about regularity exist, particularly of bowel function, and self-treatment commonly occurs to correct perceived problems.

Elimination pattern dysfunction affects interpersonal interactions (Brito-Brito et al., 2014). Lack of control affects body image (self-perception), activity level, socialization, and sleep patterns. Age, developmental levels, and cultural considerations direct the interview. Pediatric assessment includes toilet training methods, whereas adult assessment may focus on regularity and patterns of dysfunction. In addition to constipation, older adults may begin to develop urinary control problems. Women past childbearing years often develop urinary stress incontinence.

Assessment includes data about regularity and control of excreta (Gordon, 2016). Nurses investigate cues suggesting constipation

patterns, diarrhea, or incontinence through focused assessment. Elimination pattern changes, pain, discomfort, and perceived problems receive attention. Data collection includes exploration of the individual's explanation of the problem, methods of self-treatment, and perceived results (Gordon, 2016).

The quantity, quality (color, odor, and consistency), frequency, and regularity of stool, urine, and perspiration determine the direction of further exploration. Nurses assess excretory mode, time patterns, and control. Encouraging discussion aims to reveal more detailed information about pattern changes, perceived problems, and elimination habits. Examination includes gross screening of specimens, noting the amount, consistency, color, and odor. Skin assessment includes careful observation and description of wound/fistula drainage.

Transition from nutrition to elimination pattern assessment can occur seamlessly. Fluid intake affects elimination. Dietary fiber affects bowel elimination patterns. Skin integrity heralds concerns about urinary incontinence, leading to additional discussion of elimination patterns. Direct questions about laxatives may be necessary because of the availability of over-the-counter treatments for constipation (Bardsley, 2015). Discrepancies between dietary intake and reported bowel regularity indicate the need for further questioning (Lee, 2015). Laxative dependency in the form of oral supplements, suppositories, or enemas may indicate knowledge deficits in the area of bowel elimination. Health education about normal bowel function, nutritional guidelines to assist the individual in elimination, or implementation of an exercise program may significantly reduce elimination pattern dysfunction. Although overuse of laxatives is generally considered a solution older adults use to cope with constipation, young adults with bulimia and anorexia should also be assessed for laxative overuse, abuse, and dependency (Elran-Barak et al., 2014). Furthermore, nurses should explore this issue with parents of children who struggle with constipation. These parents may rely on excess use of stimulant laxatives for the effected child, resulting in chronic laxative use.

Urinary frequency and urinary tract infection (UTI) require health education as well. Several approaches to prevention of UTIs in women have some evidence to support their use (Harvard Women's Health Watch, 2015). Drinking 8 ounces of cranberry juice a day for 6 months to a year, low-dose prophylactic antibiotics, vaginally administered estrogen to promote growth of lactobacilli in postmenopausal women, and probiotic vaginal suppositories containing lactobacilli for premenopausal women have each been shown to be effective in preventing UTI in some women. Presenting symptoms of UTI in both men and women include urinary urgency, urinary frequency, and nocturnal polyuria. Research indicates that prolonged time between urinations is linked to UTIs (Harvard Women's Health Watch, 2015; Nazarko, 2015). Evidence-based practice guides the nurse in establishing a more suitable elimination routine for the individual.

Activity-Exercise Pattern

The activity-exercise pattern centers on activity level, exercise program, and leisure activities. Parameters to explore include movement capability, activity tolerance, self-care abilities, use of assistive devices, changes in pattern, satisfaction with activity and exercise patterns, and any perceived problems (Gordon, 2016). Limitations in movement capabilities or ability to perform activities of daily living significantly alter lifestyle and may affect every other functional health pattern. Mobility and independent functioning in self-care are almost universally valued. Childrearing practices demonstrate this value: parents boast about their infant who walks early, their toilet-trained toddler, and their preschooler who dresses without assistance.

Activity-exercise patterns provide effective indicators for commitment to health promotion and prevention (Figure 6-1). Exercise's impact on health status has been extensively documented with increased public awareness. Overweight and obesity, linked to sedentary lifestyle, has reached epidemic proportions worldwide. More than 1.9 billion adults (39%) are overweight, with 13% of the world's population designated as obese (World Health Organization,

2015). The World Health Organization also regards 42 million children younger than 5 years as either overweight or obese. The obesity epidemic extends from developing countries with undernourished populations to industrialized nations. Worldwide obesity prevalence has doubled since 1980 (World Health Organization, 2015). Modifiable habits such as tobacco use, poor nutrition, and sedentary lifestyle contribute to half of preventable deaths globally (National Research Council & Institute of Medicine, 2015). Assessments, plans, and interventions to prevent obesity have a major impact on global health and health promotion in the United States.

FIGURE 6-1 Activity-exercise patterns provide effective indicators for commitment to health promotion and prevention.

Activity-exercise patterns also indicate energy expenditure and activity tolerance levels. Movement directly affects activities of daily living, along with control of the immediate environment. The environment contributes to mobility as well. For example, individuals living alone in high-crime areas may limit their activity for fear of harm. Factors such as inclement weather, distance from public transportation, lack of outdoor spaces, and negotiating stairways with a cane can also influence decisions about activity (Gebel, 2015; Oreskovic et al., 2015). Environmental barriers significantly impair exercise activity patterns for individuals with neuromuscular or perceptual disturbances. Moreover, leisure activities provide clues to individuals' value systems (Sahlqvist et al., 2015). For example, work ethic, socioeconomic status, competitiveness, stage in career, and age influence how individuals perceive leisure and recreational activities.

The objective of assessment within the activity-exercise pattern is to determine the pattern of activities that require energy expenditure. The components reviewed are exercise, activity, leisure, and recreation (Gordon, 2016). The nurse seeks clues to discover strengths and weaknesses within the pattern. Decreased energy levels, perceived problems, coping strategies, changes within the patterns, and associated explanations for these changes are all important clues that require further exploration. Generally, individuals with respiratory or cardiac disease warrant in-depth assessment, and focused assessment is indicated for individuals with neuromuscular, perceptual, or circulatory impairments.

The dimensions to be described and assessed within the activity-exercise pattern include daily activities, leisure activities, and exercise. Daily activities include occupation (position, hours of work or school, and amount of physical exercise versus cognitive or sedentary activities), self-care abilities (feeding, bathing, grooming, dressing, and toileting), and home-management routines (cooking, cleaning,

shopping, laundry, and outdoor activities) (Gordon, 2016). Problems within any of these areas require explanation. Is it a problem of energy expenditure, mobility limitations, or decreased motivation caused by depression, grieving, or incongruent values?

Exercise parameters include the type, frequency, duration, and intensity of the individual's regular exercise. Nurses also assess the value the individual places on exercise as a part of determining their (i.e., the individual's) feelings about it. A 24-hour recall of the previous day's activities provides an initial picture of the pattern, whereas each major component addresses specific elements. Weekly logs provide follow-up assessment for suspected problems (Gordon, 2016). In addition to weekly logs, focused assessments include details about modes of transportation. Is a car used for transportation? If public transportation is used, how far away is the route? Are elevators or stairs used more often? Factors interfering with exercise or mobility include dyspnea, fatigue, muscle cramping, neuromuscular or perceptual deficits, chest pain, and angina. As with other patterns, feelings of satisfaction and perception of problems provide valuable indications of dysfunctional or potentially dysfunctional patterns.

Nurses evaluate subjective complaints, such as dyspnea, noting an individual's difficulty with breathing during the interview and physical examination. Examination includes objective circulatory, respiratory, and neuromuscular indicators. Assessment also includes skin color, skin temperature, apical heart rate, radial heart rate, and blood pressure, as well as respiratory rate, rhythm, depth of inspiration, and effort involved. Gait, posture, and balance are evaluated during ambulation. Muscle tone, strength, coordination, and range of motion provide useful clues to validate reports of activity and exercise. Assistive devices or prostheses are evaluated for proper use, proper fit, and degree of assistance or support provided.

Information obtained during the interview is linked closely to the examination findings. Examination alone may not disclose the invaluable subjective reports of early morning pain and joint stiffness. When appropriate, the nurse may ask the individual to climb stairs or perform self-care activities under observation to assess impairment.

Direct observation validates assessment findings and is a valuable technique used by health care educators and home health nurses to evaluate adequate performance of self-care activities, such as dressing, cooking, and insulin administration. Various instruments have been designed to quantify the level of ability or disability. For some individuals, a metabolic activity index, in which each activity is measured according to kilocalories of energy expended per minute, helps to quantify assessment results and plan care.

Developmental norms have been established for infants and toddlers. Milestones such as sitting, crawling, walking, running, and hopping determine a child's development and should be screened in children with use of standardized screening instruments (Tonelli et al., 2016). Careful assessment of ability, limitations, and interests helps to guide the nurse in a more holistic assessment. Problem identification is reserved for the conclusion of the assessment after all 11 patterns have been constructed. Useful clues within a pattern lead into other pattern areas; however, premature closure of a topic during the examination is avoided. At this point, only tentative diagnoses are possible. Often explanations of problems lie in other functional health patterns. For example, when the individual expresses an inability to perform exercise on a routine basis, barriers may be discovered in another pattern. Barriers may be associated with knowledge deficit, the personal or family value system, overriding priorities, or low value placed on exercise. Is the inability to perform activities a result of general fatigue caused by inadequate or decreased sleep time associated with anxiety, nocturia, pain, or an infant waking every 3 hours for feeding? Are responsibilities associated with caring for several preschoolers and inadequate financial resources to secure a babysitter the cause? The assessment's purpose is to narrow the number of possible explanations.

Sleep-Rest Pattern

Perhaps the single most important factor assessed in the sleep-rest pattern is the perception of adequacy of sleep and relaxation. Subjective reports of fatigue or energy levels provide some indication

of the individual's satisfaction. People make assumptions about the roles that sleep and rest play in preparing the individual for required or desired daily activities. This pattern becomes extremely important when sleep and rest are perceived as insufficient. Sleep serves a restorative function in most individuals. Sleep deprivation studies provide vivid demonstrations of the need for different types of sleep: light, deep, dream, and rapid eye movement sleep. Again, problems within this pattern may cause problems in other patterns. A person who has difficulty with sleep may be tense and irritable, unable to tolerate stress, more prone to infectious processes, and incapable of making health-promoting relationships. Appetite alterations, elimination difficulties, and activity intolerance may occur (Luyster et al., 2015). Some degree of cognitive dysfunction generally occurs as well.

The objective when the nurse is assessing the sleep-rest pattern is to describe the effectiveness of the pattern from the individual's perspective (Gordon, 2016). Wide variation in sleep time (from 4 hours to more than 10 hours) does not necessarily affect functional performance; different individuals require different amounts of sleep. Difficulty experienced with sleep onset, sleep interruptions, and awakening are areas of assessment to consider. The nurse also evaluates disturbances such as dreaming and nightmares, sleepwalking, nocturnal enuresis, and penile tumescence. Counseling, institution of safety measures, or medical referral may be necessary. In addition to sleep, the nurse assesses rest and relaxation according to the individual's perceptions. Activities of the sedentary isolate type, such as reading or crocheting, may be relaxing for some individuals. Passive involvement, as with television viewing, may provide the only source of relaxation for the individual. Daily naps or relaxation exercises (meditation, yoga, or breathing exercises) may also be a part of this pattern.

Assessment parameters of the sleep dimension are divided into two parts: sleep quality and sleep quantity. Sleep quality includes the individual's perception of sleep adequacy, performance level, and physical and psychological state on awakening. Sleep quantity, in

addition to focusing on the hours slept each day, is used to build a schedule of sleep times. The nurse assesses the individual for regularity of the time of retiring, time of awakening, and additional periods of sleep throughout the day. Sleep onset, the number of awakenings, and the reasons for awakening provide clues to problems. The dimensions of rest and relaxation include the parameters of the type, frequency or regularity, and duration. The perceived effectiveness of methods used to promote rest is also assessed.

When problems exist, focused assessment that evaluates efficiency of sleep compared with actual sleeping time is warranted. Individuals are conditioned to sleep under certain circumstances, and maintaining bedtime rituals is a distinct advantage in sleep promotion. A person who expects to sleep will usually sleep if such routines are maintained. Nurses assess schedule and routine changes associated with bedtime. When assessing bedtime routines, rituals along with other aids to sleep, such as natural aids (warm milk) or medications (prescription and nonprescription), should be explored. Physical examination includes general appearance, behavior, and performance changes. As with pain, sleep is a subjective experience. Comprehensive examination, which is beyond the scope of this chapter, may be performed, including polysomnography when indicated. Research indicates that subjective reporting of sleep quality and measures of sleep time closely approximate electroencephalographic findings.

Nursing care focuses on the need to identify evidence of sleep disturbances to design appropriate interventions before sleep deprivation occurs. Frequent awakenings do not necessarily imply sleep interruption. Many individuals awaken numerous times during the night but return to sleep within seconds. These awakenings occur in older adults, who generally spend most of the night in stages of light sleep. The normal developmental pattern of aging does not include deep sleep; therefore awakenings may not affect the sleep cycles. Older individuals, however, more often have trouble returning to sleep because they experience discomfort or anxiety. Biological

rhythm and peak performance time may be helpful to the nurse when he or she is planning health education and return visits. Individuals commonly refer to themselves as morning people or night owls; therefore patterns of retiring and arising provide clues. Patterns of sleep and rest in conjunction with subjective reports of physical and mental well-being help determine appropriate interventions.

Cognitive-Perceptual Pattern

Cognitive patterns include the ability of the individual to understand and follow directions, retain information, make decisions, solve problems, and use language appropriately. Auditory, visual, olfactory, gustatory, tactile, and kinesthetic sensations and perceptions determine perceptual and sensory patterns. Pain perception and tolerance are analyzed within this pattern area (Gordon, 2016). Capacity for independent functioning is considered a major role of thinking and perceiving. Compensation for cognitive-perceptual difficulties ensures safety. Health requires a balance between the individual and the environment. Decreased levels of cognition or perception require increased levels of environmental control. For example, mentally-impaired or sensory-impaired individuals may require sheltered work environments and supervised group living arrangements.

Interrelationships among the individual, the developmental stage, and the environment contribute to several patterns. For example, the behavior patterns of a 20-year-old high school "dropout" who works in a factory may differ from those of a 20-year-old second-year premedical student. Developmental stage plays a role in cognitive and perceptual abilities as well. Vision and hearing achieve full potential when children reach school age, with 20/30 vision considered normal in preschoolers. Developmental stage determines the ability to solve problems and conceptualize as described by the theorist Piaget (2003). As adults mature, visual acuity and the senses of hearing, touch, and even taste decline. Cognitive function must be evaluated within the context of the environment (Gordon, 2016). Environmental complexity results in different levels of functioning.

Assessing cognitive-perceptual patterns includes evaluating language capabilities, cognitive skills, and perception related to desired or required activities (Gordon, 2016). Nurses address clues indicating potential problems, particularly sensory deficits, sensory deprivation or overload, and ineffective pain management. Cognitive dysfunction may cause impaired reasoning, impaired judgment, or knowledge deficits related to health practices, as well as memory deficits.

Assessment parameters include hearing and vision test results. Changes in sensation or perception should be noted. In addition to decreased ability or acuity with regard to hearing, vision, smell, and taste, evaluation includes other perceptual disturbances, such as vertigo; increased or decreased sensitivity to heat, cold, or light touch; and visual or auditory hallucinations or illusions. Use and perceived effectiveness of assistive devices, such as hearing aids, eyeglasses, and contact lenses, is also noted.

Discomfort and pain are evaluated further. Useful tools that use pain scales have been designed to record and quantify changes in pain perception (Cunha Batalha et al., 2015). The location, type, degree, and duration of pain provide indicators of possible causes or sources. Relief measures to control pain and their effectiveness both provide data as well as a focus for health education. Attitudes toward pain should be considered. For example, someone may fear that medication is a sign of weakness or that it will result in a loss of independence. A pharmacological approach may be complemented with nonpharmacological strategies, such as heat or cold applications, distraction (music, reading, television), guided imagery, music therapy, and structured relaxation techniques (Cunha Batalha et al., 2015; Malcolm, 2015). For all individuals, exploring tolerance to pain is appropriate, using questions such as "Do you feel you are particularly sensitive to pain?" and "What level of pain is associated with your (cut, sprain, broken bone, or labor contractions)?"

Other areas of cognitive patterning to be explored include educational level, recent memory changes, ease or difficulty in learning, and preferred method of learning. Even when no problems

are apparent or suspected, the nurse may assess these areas in more detail to determine areas of strength for use with health teaching plans.

Objective data are accumulated throughout the interview or assessment process. This data collection begins with the nurse's perception of the individual's general appearance: hygiene and grooming, proper use of clothing, neatness and appropriateness of dress, and indication that these are appropriate to the individual's developmental stage. Language and vocabulary use, the ability to convey an idea with words or with actions when speech is impaired or not yet developed, and grammatical correctness provide clues to cognitive functioning. Amplitude and quality of speech, affect and mood, as well as attention and concentration are all indicative of the individual's mental status. For many individuals, this information is sufficient to relay a sense of the level of understanding, memory, and mentation. Problem-solving abilities can usually be determined when the individual is asked to relate any perceived problems, provide an explanation of the problems and/or actions taken to solve the problems, and describe the results of the actions taken. Because this is a basic assessment in each functional health pattern, the nurse already has an idea of whether thought processes are logical, coherent, and relevant for this individual.

When problems within the cognitive realm do not surface, the information is recorded as part of the objective data or findings of the physical examination. The data to be noted include language; vocabulary; attention span; grasp of ideas; level of consciousness; orientation to person, place, and time; language spoken (whether primary or secondary); and behavior during the data collection process, including posture, facial expression, and general body movements.

When a problem is apparent or suspected based on age, hereditary factors, or inconsistencies in the assessment data, a focused assessment is essential. Coma scales or functional dementia scales may be appropriate. More commonly, a Folstein Mini–Mental Status Examination (MMSE) is performed to assess orientation, attention,

calculation, language (ability to name objects, repeat abstract ideas, and follow commands), and recall (immediate, short-term, and long-term memory). Abilities to read, write, and copy designs can also be assessed (see Chapter 24). The examination of a sensory-perceptual pattern evaluates hearing, vision, and areas of pain at a screening level; comprehensive examinations are available and may be indicated. A full neurological assessment is warranted when specific sensory deficits are identified during the examination.

Although completing these assessment areas may seem overwhelming, the time required is generally less than that in most other pattern areas, perhaps because more information relevant to the cognitive-perceptual patterns becomes available as each pattern is assessed. Transition into the cognitive-perceptual pattern from other patterns may be facilitated by referring to a problem already described, with a question such as "Do you generally find it easy to solve problems effectively?" The self-perception pattern follows the cognitive pattern particularly well because mental status measures include feelings and perceptions of the individual regarding self. Mood, affect, and responses to the interviewer, such as eye contact, are indications of self-esteem. Cognitive-perceptual ability greatly influences the ability to function (self-care) or manipulate (activity and exercise) within the environment.

The placement of each of the patterns in a sequence suitable to each nurse, individual, or situation has been discussed. When the cognitive-perceptual pattern is dysfunctional, however, the individual is most likely unreliable as the historian; therefore it is wise to consider this pattern early in the assessment process. Approaching this pattern early saves valuable time and permits the identification of patterns that can be assessed more reliably.

Every person has experienced temporary memory lapses at one time or another. These events alone are not a sufficient basis for judgments. Sequencing of behaviors and clustering of appropriate signals (defining characteristics) are necessary to determine any nursing diagnosis. Equally important is the need to assess all pattern areas before data analysis and problem identification.

Cognitive and sensory ability data guide the nurse in planning care, which is especially apparent in health teaching. Formulation of health teaching plans ideally reflects each individual's preferred method of learning. The effective plan considers the individual's demonstrated developmental level; the ability to store information, retrieve information, and compensate for deficits; and also the neuromuscular and sensory levels necessary for skills development. An individually tailored plan contains mutually developed goals and short-term objectives. Although self-care might be an outcome for any person in whom diabetes mellitus has been newly diagnosed, the behaviors expected of an adult with diabetes will differ from those expected of a child.

Self-Perception–Self-Concept Pattern

The self-perception–self-concept pattern encompasses the sense of each individual's personal identity, goals, emotional patterns, and feelings about the self. Self-image and sense of worth both stem from the individual's perception of personal appearance, competencies, and limitations, including the individual's self-perception and others' perceptions. The nurse assesses physical, verbal, and nonverbal cues (Gordon, 2016).

The significance of the sense of self to the whole person is best exemplified by personal experiences. Individuals who feel good about their self worth look and act differently from those who feel unable to accomplish anything worthwhile. Self-concept changes may affect patterns of eating, sleeping, and activity.

The individual's developmental level affects and is affected by this pattern. One of the tasks identified during the later phases of Erikson's developmental framework, described previously, is building wholesome self-esteem. Delays in self-esteem and self-concept development affect progress toward subsequent tasks (Blakely-McClure & Ostrov, 2016) (see Table 6-3).

Family climate and relationship patterns provide the environmental impact that influences the self-concept pattern (see Chapter 7). People who are closely associated with the individual affect that person's self-

esteem. Most people care about what others think of them; therefore the support of significant others affects the self-perception–self-concept pattern (Tranväg et al., 2015; Philips, 2015) (Figure 6-2).

FIGURE 6-2 Most people care about what others think of them; therefore the support of significant others, such as a grandmother supporting a student grandchild, affects their self-perception–self-concept pattern.

The assessment objective in this pattern area is to describe each individual's patterns and beliefs about general self-worth and feeling states (Gordon, 2016). The nurse looks for clues that indicate identity confusion, altered body image, disturbances in self-esteem, and feelings of powerlessness. Nurses often identify anxiety, fear, and depression states that are responsive to nursing interventions (Webb et al., 2015).

The nurse notes the general appearance and effect of each individual, which may have been assessed as part of a formal mental status examination. Low self-esteem may be indicated by head and shoulder flexion, lack of eye contact, and mumbled or slurred speech.

Anxiety or nervousness might be revealed through extraneous body movements such as foot shuffling or tapping, facial tension or grimace, rapid speech, voice quivering, twitches or tremors, and general restlessness or shifts in body position. Any of these indicators demands further exploration to determine underlying problems for each individual.

Self-concept influences each individual's interaction with others. In their study of 74 graduating college students, Wilt and colleagues (2016) linked meaning in life (MIL) to psychosocial functioning and self-concept at a time when the participants were embarking on a major life transition. The concept of MIL incorporates the belief that life is comprehensible and existence is important. Participants in this study who interacted with their family and friends had a higher level of MIL than those participants who experienced graduation and academic life without such interactions (Wilt et al., 2016).

Because the information in this pattern is personal, sharing the information may actually facilitate the process of goal setting and intervention planning when the nurse possesses strong communication skills and a caring attitude.

Roles-Relationships Pattern

The roles-relationships pattern describes the position assumed and the associations engaged in by the individual that are connected to that position. The individual's perception is a major component of the assessment, and exploration of the pattern includes each individual's level of satisfaction with roles and relationships.

The need for relationships with other people is universal. Dossey and colleagues (2016) have identified basic needs for communication, fellowship, and love in high-level wellness. The ability to communicate with other people in a meaningful way greatly affects the whole person. The understanding of health as the harmonious balance between the individual and the environment indicates the major role that relationships with others play in health. Developmental hypotheses about readiness propose that attainment of each stage is required to progress to the next stage. For example, a

person can become immersed in a relationship of genuine intimacy only after self-identity has stabilized. Developmental tasks that promote family development have also been identified similarly by Duvall and Miller as noted by Gilbert (2015) (see Chapter 7). The emphasis within these models is on the individual's relationships within the nuclear family.

The objective of the roles-relationships pattern assessment is to describe an individual's pattern of family and shared circumstances, with the associated responsibilities. The individual's perception of satisfaction with the established relationship contributes to this assessment. Loss, change, and threat produce the major problems within this pattern. Clues indicative of impaired verbal communication, social isolation, alterations in parenting, independence-dependence conflicts, dysfunctional grieving, and potential for violence are pertinent.

Assessment focuses on family, work, and community roles and relationships. Within the family, assessment parameters include the family structure, tasks performed, social support systems, and other dynamics, such as decision-making, power, authority, division of labor, and communication patterns. Parenting or marital difficulties and family violence issues are explored. The roles of student and employee are explored to determine specific occupation or position, along with work responsibilities and work environment. Parameters such as stress, safety, and health factors should be included (see the case study and the care plan at the end of this chapter). Financial concerns, job security, and retirement plans are elicited. Activity-rest patterns elicit information about time commitments, leisure activities, and physical exercise; therefore the assessment at this point addresses the impact of these factors on the roles-relationships pattern. Community roles and relationships indicate involvement within the neighborhood and other social groups, such as the level of socialization and the amount of social support available. Within all three components (family, work or school, and community) the individual is asked to describe the level of satisfaction with the roles and relationships.

Threat of change, actual change, and loss are areas to be explored further. In addition, family or work roles alone may not cause stress, but combining them may cause difficulties, as with the working mother or traveling husband and father.

Objective data for assessment within this pattern are usually unavailable unless the nurse makes a home visit or sees the individual in the company of significant others in some other capacity. Family interaction and communication patterns are noted whenever possible. Cognizant of meaningful relationships within the family, the nurse identifies potential problems, such as those that occur with the college student away from home, the individual who travels or moves frequently, and sole family survivors when older adults outlive their family members and friends (Gilbert, 2015). The relationships among the functional health patterns are clearly apparent in light of the developmental stages. Difficulties within the self-concept pattern and difficulties with relationships often appear together (Thomé et al., 2014). Relationships affect the whole person; therefore problems in the roles-relationships pattern may be exhibited in other areas, such as sleep, appetite, and sexuality.

Sexuality-Reproductive Pattern

The sexuality-reproductive pattern describes the individual's sexual self-concept, sexual functioning, methods of intimacy, and reproductive areas. Data collection combines subjective information, nursing observations, and physical examination. Normal development and perceived satisfaction combine to provide the elements of this pattern (Gordon, 2016).

Sexuality is the behavioral expression of sexual identity. The importance of this pattern area to the individual's life and health is closely related to the self-perception and the relationships patterns. Body image, self-concept, and role and gender identity are linked to sexual identity. This concept of sexual self and the individual's relationships pattern indicate the level and the perceived satisfaction of sexual functioning. Sexual functioning involves, but is not limited to, sexual relations with a partner. Reproductive patterns are equally

significant to this pattern assessment, the whole individual, and the family and community (see Chapters 7 and 8).

As discussed, individual development influences reproductive capacities; these include genotype, secondary sex characteristics, genital development, phenotype, ego integrity, and the family life-cycle stage (Gilbert, 2015). The environment also plays a part in expression of the sexuality-reproductive pattern. Cultural and family norms may contribute to the expression of sexuality and combine with other factors, such as the family's financial stability, to influence reproductive patterns (Sutherland et al., 2015). Norms within society may create issues in expressions of sexuality.

During the assessment process, nurses consider the continuum of sexual identity expression, including heterosexuality, bisexuality, and transgender, gay, or lesbian sexuality. The information gathered guides the health-promotion plan in those who inquire about their sexual identity. Cochran and colleagues (2016) indicate that sexual orientation influences the risk of death in their analysis of National Health and Nutrition Examination Survey data. Heterosexual participants (n = 14,521) were more likely to experience lower death risk than their nonheterosexual counterparts (n = 1045). These findings were consistent with the view that sexual orientation–related health disadvantages create this disparity in death risk. Nurses should remain informed about sexual orientation health disadvantages, such as mental distress, tobacco use, binge drinking, and lack of health insurance.

One objective of assessment in this pattern is to describe behavioral problems or difficulties (Gordon, 2016). Equally important is assessing the individual's knowledge of sexual functioning and preventive health practices, such as breast and testicular self-examination, Papanicolaou tests, effective contraceptive use, and avoidance of infection. Clues are evaluated for potential or actual sexual dysfunction.

The following parameters are assessed: sexual self-concept, which may be derived from information collected in the self-perception–self-concept and the roles-relationships patterns; sexual functioning, with

the nurse noting evidence of some form of intimacy, the level of sexual activity or libido, and the effect of health or illness on sexual expression; and reproductive patterns, in which the nurse collects data pertinent to health-promotion factors, such as feelings related to aging, preventive practices, and knowledge of sexual functioning. For women, reproductive pattern assessment would also include information about menstruation, such as onset, duration, and frequency, date of last menstrual period, discomfort, and menopause, as well as information about reproductive stage, such as pregnancy history and birth control methods.

The level of satisfaction with sexual self-concept, sexual functioning, and reproduction is also explored. Difficulties such as ineffective or inappropriate sexual performance, discharges, infections, venereal disease, discomfort, and history of abuse are evaluated. Focused assessment to collect additional information is warranted with sexual dysfunction or trauma. Physical examination evaluates genital development and secondary sex characteristics. Signs of intimacy between partners, such as holding hands and hugging, are noted.

People may feel threatened by discussion of topics in this pattern; the depth of exploration is governed in part by the individual's wishes. Dialogue is encouraged but may be postponed until a firm and trusting relationship is established. A clear representation of the individual's knowledge and use of preventive practices facilitates planning for health promotion. Although sex education is usually associated with school programs, information and discussion about sexuality is just as important for adults of all ages. Sex education is a key element of parenthood classes. Improved understanding of sexuality and sexual function leads to discovery and increased satisfaction.

Coping–Stress Tolerance Pattern

Gordon (2016) describes the coping–stress tolerance pattern as a depiction of general coping and the individual's ability to effectively manage stress. This pattern includes the individual's ability to process

life crises and to resist disruptive factors that will influence self-integrity of ego, mode of conflict resolution, stress management, and accessibility to necessary resources (Box 6-3: Quality and Safety Scenario).

Box 6-3

Quality and Safety Scenario

Improving the quality of health promotion was explored in four primary health centers in Australia. These centers served Australian Indigenous people. The researchers aimed to describe the scope and quality of health-promotion activities and introduce health-promotion interventions. The findings suggest that quality-improvement projects can improve the delivery of evidence-based health promotion by engaging front-line health practitioners in redesign of systems. In addition to medical care, primary health centers that have health promotion as a core function should also deliver counseling, preventive medicine, health education and promotion, rehabilitative services, antenatal and postnatal care, and maternal and child care programs. Often organizational support for such core functions is inadequate. This study attempted to engage the centers in a systems approach to quality improvement to address the organizational components that hindered health-promotion delivery. The researchers used an iterative action research strategy to explore current practice, introduce best practices, and engage physicians, nurses, Aboriginal health workers, and administrative staff in the action plan to redesign health-promotion delivery systems within the four primary health centers.

The ability to manage stress effectively in life is a learned behavior. Stress is a necessary part of life; without it there is no motivation to grow. Vulnerability to stress may be linked to individuals' coping

strategies, such as avoidance behavior (Gorka et al., 2016). Stress is exacerbated by accumulation of minor irritations. Stress is inherent not in the event but in the individual's perception of that event. Whereas one individual may experience stress from missing a bus and can think only of being 10 minutes late, another will consider the same event an opportunity to spend 10 minutes reading the newspaper. This difference in perception may represent the different values used to identify sources of stress or it may represent coping strategies.

For purposes of assessing this pattern, coping, which is considered the individual behavioral response to stress, includes both problem-solving ability and use of defense mechanisms. Coping is viewed not as a single act but as a process incorporating many behaviors. The function of coping is to deal with the threat or emotional distress of an event. Coping effectiveness is assessed from the individual's perspective and from the nurse's observation of the individual's ability to function in the presence of actual or potential stressors in the environment.

The perception of stress and the ability to manage it depend on personal development, the amount of stress previously experienced, the current level of stress within the environment, and the sources of social support. For example, an older adult may experience many stresses during life and manage them effectively, but now coping may no longer be possible because too many stressors are present, such as physical incapacitation, fixed income, fear of illness or injury, and lack of transportation (Bielderman et al., 2015; Boehm et al., 2015). In addition, this person may no longer have a social support system, which has been associated with promotion of health. Determining individuals' stress tolerance and past coping patterns becomes the objective of assessment for this functional pattern. Clues to difficulties in managing past and current stressors and changes in the effectiveness of a coping pattern help to determine personal coping capacity.

The following assessment parameters are included: the coping task, including the physical, psychological, and socioeconomic stimuli with which the individual must cope; coping style, or the tendency to use a

specific style, such as approach oriented, avoidance oriented, or nonspecific; coping strategies, including specifics; and coping effectiveness. Coping strategy may be divided into information seeking, direct action (fight or flight), inhibition of action, or use of social support. Individual resources include the variety of coping mechanisms used by the individual, the flexibility of these mechanisms, and the health-promotion value associated with each of them. For example, in their study of problem-solving intervention with 166 stroke rehabilitation clients, Visser and colleagues (2016) report that their problem-solving intervention improved task-oriented coping and general health-related quality of life. However psychosocial health-related quality of life associated specifically with stroke in their sample did not seem to improve.

Stress tolerance patterns elicit the amount of stress effectively processed in the past. Use of anticipatory coping is assessed along with whether the individual knows how to cope, but does not cope (production deficit), or simply does not know how to cope (skill deficit). Other indicators of value within this pattern are discussed in the section Self-Perception–Self-Concept Pattern. Objective data of concern include physical signs of restlessness, irritability, and nervousness, such as increased heart rate, blood pressure, and perspiration. Evidence of coping ability and tolerance to stress are found in every other functional health pattern. Stress also affects the other patterns, thereby resulting in health problems such as insomnia, weight loss, and poor concentration (Dossey et al., 2016; Gordon, 2016).

Health can be promoted through early intervention to reduce stress. Coping patterns and stress tolerance in the past may uncover unhealthy coping behavior, such as smoking and alcohol consumption, that needs to be replaced by alternative coping strategies. Stress-reduction workshops would be helpful for most of the population because the future undoubtedly holds stressful events, some of which may be overwhelming without coping strategies. Box 6-4: Innovative Practice includes information about a unique company that offers stress-management interventions. Dossey and colleagues

(2016) offer categories for stress management: social engineering strategies, such as time management or planned change; personality engineering strategies, such as assertiveness training or cognitive rehearsal; and altered states of consciousness, such as meditation or relaxation. Planning based on the assessment of all functional health patterns to help determine a coping pattern should include these kinds of strategies.

Box 6-4

Innovative Practice

The Humor Potential Inc.

The Humor Potential, Inc., is a company that provides resources, products, and seminars for stress management with the use of humor. Company president Loretta LaRoche is a recognized expert on stress management, emphasizing the importance of balancing daily living experiences with humor. The Humor Potential offers seminars and lectures to health care professionals, schools, corporations, other organizations, and the general public. The company also produces television programs that have been televised nationally in the United States. One television program, *The Joy of Stress,* was nominated for a regional Emmy Award.

Books, prints, audiotapes and videotapes, and other products dealing with humor can be purchased from Loretta LaRoche's website. The collection consists of audiotapes and videotapes that have been developed for corporate meetings and training. An example is *Lighten Up!* This is a videotape and action guide that increases productivity by reducing stress. A catalog is available for e-mail, fax, phone, and mail orders.

Values-Beliefs Pattern

The values-beliefs pattern describes values, including the individual's spiritual values, beliefs, and goals. This pattern also includes perceptions of what is right, what is good, and conflicts that beliefs or values impart. Each of the 11 patterns addresses the value systems of individuals, their family, and society. Individual beliefs or values develop over time and govern life through personal experiences and family and societal influences (Boehm et al., 2015; Bielderman et al., 2015). The objective in assessing this pattern is to determine the basis for health-related decisions and actions (Gordon, 2016). Individuals engage in preventive health behavior when a threat to wellness or health status exists. Several other health belief models expand on this concept by including other motivations, such as personal values and environmental influences. Clues to conflict within the individual's value system or between the person's value system and that of the family or society are explored.

The dimensions of assessment include the individual's values, beliefs, or goals that guide choices or decisions that are related to health. The nurse collects information while exploring each pattern, while summarizing, clarifying, and securing additional information. Specifically, values and beliefs about self, relationships, and society are appraised. Individuals' beliefs, goals, and purposes of life are reviewed, along with any conflicts, perceived philosophies, and philosophies of the family, culture, and society. Sources of strength, such as a higher being or significant individual practices, are explored, including religious beliefs and preferences. Past goals and

expectations are assessed through the individual's satisfaction. The nurse must identify the individual's goals and expectations concerning health, clarifying them to help the individual achieve them. To be effective, health-promotion interventions are based on the individual's value system and health beliefs (Dossey et al., 2016). The brevity of this discussion is not an indication of the importance that the values-beliefs pattern plays in the assessment of the individual. Individual values play a role in all the patterns.

Individual Health Promotion Through the Nursing Process

The nursing process—the systematic approach to reduce or eliminate the individual's health problem—is accomplished in several steps, the first being the collection of necessary data. With the individual, the nurse analyzes the data, identifies a nursing diagnosis, projects outcomes, prescribes interventions, and evaluates effectiveness. Reassessment, reordering of priorities, new goal setting, and revising the plan continue as part of the process toward outcome attainment (Carpenito-Moyet, 2012).

Collection and Analysis of Data

Assessment is a systematic technique for learning as much as possible about the individual. The main purpose in collecting data from a new individual is to see whether health problems exist and to identify the individual's health goals. Data collection includes biographical data, such as age, sex, and the purpose of the visit. This process is followed by assessment of the previously outlined 11 functional health patterns. Subjective reporting, nursing observations and perceptions, and the physical examination findings are assessed and recorded. The remaining discussion focuses on nursing diagnosis.

Problem Identification

As the concept of problem identification evolved, most nurses have distinguished *nursing diagnosis* as the most useful label. Diagnosis is a careful examination and analysis of the facts to provide a basis for nursing intervention. Nursing diagnosis is the naming of individual, family, and community responses to actual or potential health problems or life processes (Gordon, 2016; NANDA International, 2011). Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable

(Gordon, 2016). Leadership from NANDA International has provided standardization of the descriptions of human responses that nurses manage. The most recent revision of this taxonomy has been approved for clinical testing and has been endorsed by the American Nurses Association (ANA) (NANDA International, 2011). Although Wang and colleagues (2015) describe issues associated with the use of the NANDA International taxonomy, such as inadequacy of terms to describe complex nursing care and nurses' reluctance to incorporate these diagnoses into their documentation language, the NANDA International taxonomy remains the most widely used standardized language for nursing diagnoses.

Gordon (2016) proposes the accepted format of nursing diagnosis that lists the problem, cause, and signs and symptoms, or defining characteristics, for each diagnosis accepted for clinical testing. The NANDA International taxonomy uses a multiaxial framework for nursing diagnoses, including diagnostic concept (e.g., parenting), acuity (e.g., altered), unit of care (e.g., individual), developmental stage (e.g., adolescent), potentiality (e.g., at risk of), and descriptor, for creation of the diagnostic statement (NANDA International, 2011). Box 6-5: Research for Evidence-Based Practice discusses how this nursing classification system compares with a nonnursing system.

Box 6-5

Research for Evidence-Based Practice

Evidence-based strategies should be used to promote individuals' health. Adolescent sexual health promotion efforts may be inaccessible and lack confidentiality. Multiple interrelated risks develop among adolescents, requiring multifaceted health-promotion strategies. Champion and colleagues (2016) aimed to explore these issues in their study exploring psychological distress, violence, and substance use among African American (n = 94) and Mexican American (n = 465) adolescent women with a history of risky sexual behavior. These adolescent women self-reported psychological distress, sexual risk behavior, sexually transmitted infection (STI),

personal and friend/peer substance use, alcohol use, and violence. Substance-using friends, physical violence, and STI were highly associated with personal substance use in these adolescent women. Alcohol users were five times more likely than nonalcohol users to use other substances.

Adolescents in this study self-reported adverse sexual health outcomes, including initial and repeated unplanned pregnancies, HIV infection, and other STIs. Predictors of substance use in these women were ethnicity, friend substance use, physical violence history, STI history, and history of alcohol use. Nurses should consider social determinants, including demographic, educational, environmental, and behavioral components, in their assessment of specific adolescent populations such as ethnic minority females. The authors recommend that nurses integrate these complex health disparities into their health-promotion practice. They aim for their findings to guide health-promotion strategies in primary care settings for women experiencing multiple health disparities.

From Champion, J. D., Young, C., & Rew, L. (2016). Substantiating the need for primary care–based sexual health promotion interventions for ethnic minority adolescent women experiencing health disparities. *Journal of the American Association of Nurse Practitioners*, *28*(9), 487–492.

In discussions of problems, the meaning of the problem must be clearly defined and identified. The concept as used in this text refers to Gordon's (2016) proposition that a health problem is defined as a dysfunctional pattern and that nursing's major contribution to health care is in preventing and treating such a pattern. A pattern is dysfunctional when it represents a deviation from established norms or from the individual's previous condition or goals. (Normative behavior is further discussed in Unit 4.) A dysfunctional pattern is a problem when it generates therapeutic concern on the part of the individual, others, or the nurse and when it is amenable to nursing therapies.

As patterns are assessed, the nurse proposes several hypotheses regarding functional or dysfunctional labeling. At the completion of the assessment, conclusions must be drawn. The possibility exists that

all patterns are functional, that some are functional, and that others are dysfunctional or potentially dysfunctional. Functional refers to wellness and optimal health. Dysfunctional patterns, indicating some health problems, may be present in the absence of disease; that is, nursing care may be needed for health promotion and health maintenance, not health restoration. The case history of Frank Thompson in Chapter 1 effectively illustrates the multiple nursing care needs of an individual who is not ill. In potentially dysfunctional patterns, sufficient evidence exists or enough **risk factors** are present to indicate that a pattern dysfunction will likely occur if interventions are not made. Early identification of potential problems is possible through systematic data collection and analysis.

Contributing Etiological Factors

To plan care the nurse must first determine what has caused the actual or potential health problem: its contributing etiological factors. The etiological factors of most dysfunctional patterns lie within another pattern or patterns. Although cause is never an absolute within human sciences, the projection of outcomes or goals must be based on probable causes. Interventions then focus on mediating or resolving the probable causes. Most often, many factors are involved, and problems are said to relate to rather than be a result of these factors. Potential problems are not actual problems but risk states; therefore they have no specific cause and are identified when risk factors are present. Nursing intervention is directed toward risk reduction through education (classes or brochures) to improve nutrition, prevent accidents, and so forth. Risk estimate theory and potential health problems are developed further in Chapters 7 and 8 and Unit 4.

Diagnostic Variables

The ability to arrive at an accurate diagnosis, even when comprehensive data are unavailable, is governed primarily by the nurse's clinical knowledge. Experience improves the effectiveness when nursing is performed as a scientific process. Nursing requires

the gathering of information, interpreting it based on normative values, organizing and grouping information on the basis of healthy findings, identifying the problem, and then planning appropriate goals and interventions. Difficulties are encountered when there are no available norms that occur frequently in the psychosocial assessment components. Use of the 11 interdependent functional health patterns helps to solve these difficulties. By focusing on each of these areas, nurses find it easier to recognize whether a problem does or does not exist. Any change within the pattern may be a sign of dysfunction or an unhealthy but stabilized behavior. For example, a sign of dysfunction might be a 2-year-old child who is still not walking; developmental growth is a major factor in activity patterns of infants, toddlers, and children.

The use of physiological parameters clearly demonstrates the idea of a stabilized dysfunctional pattern, but equal attention must be given to psychological development. For instance, a 26-year-old man who lives with his mother and gives no indication of independent decision-making should be evaluated. It should be apparent that assessment information primarily comes from the initial contact with the individual and the database, which is generally the case in health-promotion activities. However, in any acute situation or emergency, quick assessment of the major problems is given high priority on a hierarchy-of-needs basis, and the full nursing assessment is postponed temporarily. For further understanding of the nursing diagnosis, the nurse is referred to those authors who discuss the development of diagnoses, the diagnostic process, and specific details of each accepted diagnosis (Carpenito-Moyet, 2012; Gordon, 2016; NANDA International, 2011).

Planning the Care

In the nursing process, planning is the proposal of diagnosis-specific treatment to assist the individual toward the goal, or expected outcome, of optimal health. The individual's goals and the determined nursing diagnosis provide the basis for planning. Clear goals and diagnoses are critical to development of an effective plan of care. The

nursing process identifies the following purposes of the planning phase: to assign priority to the problems diagnosed; to specify the behavioral outcomes or goals with the individual, including the expected time of achievement; to differentiate individual problems that can be resolved by nursing intervention, those that can be handled by the individual or family member, and those that should be handled with or referred to other members of the health team; to designate specific actions, the frequency of these actions, and the short-term, intermediate-term, and long-term results; and to list the individual's problems (nursing diagnosis) and nursing actions (frequency and **expected outcomes,** or goals) on the nursing care plan or blueprint for action (Carpenito-Moyet, 2012). This plan provides the direction for individual and nursing activities and is the guide for the evaluation. There are many research studies involving outcomes from which nurses can draw to increase the effectiveness of the care they provide.

Implementing the Plan

Implementation consists of the actions necessary to fulfill the goals for optimal health; it is the enactment of the nursing care plan to elicit the behaviors described in the proposed individual outcome. The selection of a nursing intervention depends on several factors: the desired individual outcome, the characteristics of the nursing diagnosis, the research base associated with the intervention, the feasibility of implementing the intervention, the acceptability of the intervention to the individual, and the capability of the nurse (Carpenito-Moyet, 2012). A nursing interventions classification is being developed. As discussed in Unit 1, a critical component of effective communication is the accurate interpretation of the individual's information. This feedback process continues throughout all phases of the nursing process; the nurse continues to collect data to modify the plan as needed and does not blindly implement the care plan. As discussed in Unit 3, the most frequently used nursing interventions in health promotion are screening, education, counseling, and crisis intervention. All these interventions require

strong communication abilities from the nurse. Checklists and screening instruments may be used to document nursing assessment and help to ensure transmission of reliable and quality information for client-centered care. Implementation requires transdisciplinary collaboration in the analysis and plan. Computerized data entry, information systems, and electronic medical records may facilitate communication; however, ongoing interaction with other health care providers is essential for collaboration.

Evaluating the Plan

The process of analyzing changes experienced by the individual occurs in the evaluation phase of the nursing process, with the nurse examining the relationships between nursing actions and the individual's goal achievement. The nursing process emphasizes that evaluation is always considered in terms of how the individual responds to the plan of action (Osborn et al., 2013). As discussed, the nursing diagnosis (or health problems) and the goal (or expected outcome) guide the evaluation of the nursing care plan. Many variables influence outcomes: the interventions prescribed by the health care providers, the health care providers themselves, the environment in which the care is received, motivation, the individual's genetic structure, and the individual's significant others (Box 6-6: Genomics). The task for nursing is to define which outcomes are sensitive to nursing care so as to identify the expected and attainable results of nursing care for each individual (NANDA International, 2011). Families and clients are partners in the process of client-centered care (Spruce, 2015). Documentation of all components of the nursing process in the individual's health care record is then performed (Osborn et al., 2013).

Box 6-6

Genomics

The *Healthy People 2020* genomics goal to improve health and prevent harm through valid and useful genomic tools in clinical and public

health practices has two associated objectives, both of which are linked to health promotion assessment of the individual.

G-1 Increase the proportion of women with a family history of breast and/or ovarian cancer who receive genetic counseling

Women with a family history of breast and/or ovarian cancer face multiple decisions that encompass both a cognitive and an emotional component. Risk estimates, disease course, family/reproductive plans, potential interventions, and timelines should be discussed. Open dialogue should include numerical risk, past experiences with cancer and deaths in the family, whether the women has children, anxiety, depression, and general risk aversion. Treatment option discussion should include the types of breast cancers that develop in *BRCA1* and *BRCA2* carriers, the role of age at diagnosis, surgery, risk-reducing medications, surveillance, and surgical options (mastectomy and salpingo-oopherectomy). Information presented clearly with time and emotional support as decisions are made is essential. The efficacy of risk-reducing mastectomy has been supported in large-scale studies; however, the efficacy and side effects of salpingo-oopherectomy are less well established. Moreover, physical and psychosexual adverse effects may accompany these approaches. A genetic counselor who specializes in these disorders is the preferred provider to provide individualized care based on the specific gene mutation.

G-2 (Developmental) Increase the proportion of persons with newly diagnosed colorectal cancer who receive genetic testing to identify Lynch syndrome (or familial colorectal cancer syndromes)

Two to four percent of all colorectal cancers (CRCs) are associated with the autosomal dominant disorder Lynch syndrome. Additionally, individuals with Lynch syndrome have a 50% to 80% lifetime risk of developing CRC. The criteria (Amsterdam II) to determine which individuals should be screened for Lynch syndrome include:

- three biological relatives with CRC or another Lynch-associated cancer (endometrial, ovarian, upper urinary tract, small bowel) who are linked through a first-degree relative;

- at least two consecutive generations affected;
- one cancer diagnosis when younger than 50 years.

Individuals who meet the criteria but choose to forego genetic screening should receive aggressive surveillance with colonoscopy every 1 to 2 years starting at the age of 20 to 25 years. Failure to identify at-risk individuals is common, and aggressive screening is often not completed.

One potential barrier is provider lack of knowledge regarding recommended screening guidelines. Nurses who promote health should be aware of these screening criteria.

From Hartmann, L. C., & Lindor, N. M. (2016). The role of risk-reducing surgery in hereditary breast and ovarian cancer. *New England Journal of Medicine*, *374*(5), 454-468; Patel, S. G., Ahnen, D. J., Kinney, A. Y., Horick, N., Finkelstein, D. M., Hill, D. A., et al. (2016). Knowledge and uptake of genetic counseling and colonoscopic screening among individuals at increased risk for Lynch syndrome and their endoscopists from the Family Health Promotion Project. *The American Journal of Gastroenterology*, *111*(2), 285-293.

Case Study

Spiritual Distress: Cindy

Cindy is a single 28-year-old woman. Cindy studies nursing and shares an apartment with two friends. She was having increasing difficulties with her course work and was placed on academic probation. Cindy became concerned about the effect of stress on her ability to finish her studies and on her future career. She grew increasingly nervous and began to ask, “Will I ever be okay?” and “Will I ever be able to finish school and function as a nurse?” Cindy expressed her fear of weakness and feelings of isolation, loneliness, helplessness, and loss of control. These feelings began to find expression in anger related to this major life disruption. She verbalized her anger at God for allowing this to happen to her. Her incapacity deprived her of her normal outlets for expressing and finding support for such concerns. Cindy was unable to participate in

the practices of her faith, in which she had previously found strength in facing life's challenges. Her inability to concentrate and her growing feeling of lethargy added to her frustration. Expressing these fears and concerns was difficult for Cindy. The nurse, however, developed a trusting relationship with Cindy, permitting her to express her fears, anxieties, and concerns. Based on the nurse's assessment, the nursing diagnosis of spiritual distress was formulated.

Reflective Questions

- What differential diagnoses should the nurse consider?
- Describe other individuals you know who have experienced spiritual distress.

Care Plan

Spiritual Distress: Cindy

***NURSING DIAGNOSIS: Spiritual distress related to a threat to well-being, loss of meaningful role, and separation from religious and family ties**

Defining Characteristics

- Experiences a disturbance in the belief system.
- Demonstrates discouragement or despair.
- Chooses not to practice religious rituals.
- Shows emotional detachment from self and others.
- Expresses concern, anger, resentment, and fear, related to a major life disruption.

Related Factors

- Threat to well-being from change in role as a student and fear of failure
- Loss of meaningful role as a student
- Separation from religious and family ties

Expected Outcomes

- Person will verbalize a greater sense of purpose, meaning, and hope.
- Person will express feelings of anger verbally and will discuss anger with another person.

Interventions

- Take time to be present and available to listen to the individual.
- Convey a nonjudgmental attitude.
- Encourage the individual to verbalize feelings.
- Pray with the individual as indicated.
- Engage the individual in values clarification.
- Encourage the individual to acknowledge feelings of anger and to acknowledge and name any other feelings experienced.
- Reassure the individual that it is acceptable to feel anger toward a supreme being.
- Encourage honest dialogue with a peer whom the individual trusts.

- Offer consultation with an appropriate spiritual advisor.
- Inform the individual of religious resources.

---

*NANDA Nursing Diagnoses—Herdman, T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses—Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Data relevant to the health-promotion activities of the individual focus primarily on the assessment of the current health status so that the nurse can identify problem areas, or areas of dysfunction, within the individual's health and lifestyle pattern. This process is a fundamental first step and precedes all other components of the nursing process. Without a clear picture of the problem, nursing activities are fruitless. Gordon's (2016) functional health pattern framework provides guidance for the individual assessment. The focus of each pattern includes the age-developmental influences exerted, cultural and environmental roles played, functional ability displayed, and behavioral patterns specific to each individual. The interaction between internal mechanisms and the environment is assessed through these 11 functional health patterns. When assessing each pattern, the nurse must understand the pattern definition, the significance of the pattern to the whole individual, the developmental influences, the environmental role, the assessment objectives, the assessment parameters and indicators, and the nursing implications. Assessment is essential to all components of the nursing process in health promotion for the individual.

Health Promotion and the Family

Anne Rath Rentfro

OBJECTIVES

After completing this chapter, the reader will be able to:

- Describe various theoretical approaches to the study of families.
- Assess families throughout the life span using the functional health pattern framework.
- Describe examples of the clinical data to collect in each health pattern during each family developmental phase.
- Provide examples of behavioral changes (functional, potentially dysfunctional, and actually dysfunctional) within the health patterns of families.
- Describe developmental and cultural characteristics of the family to consider when identifying risk factors or etiological factors of potential or actual dysfunctional health patterns.
- Plan, implement, and evaluate nursing interventions in health promotion with families.
- Evaluate a specific health-promotion plan based on family assessment, nursing diagnosis, and contributing risks or etiological factors.

Think About It

Caring for Older Adults

Adult family members, who may have health problems of their own, find themselves caring for their older adult parents as well as grandchildren. Increased life expectancies combined with increased age at the birth of the first child present adults with the caring for older parents along with young children (Suh, 2016). This population, known as the sandwich generation, is expected to become more prevalent in the coming years. An increasing number of parents of children older than 18 years provide financial support or care for grandchildren younger than 18 years along with caring for an older parent aged more than 65 years (Suh, 2016).

- What are the implications of this growing situation for individuals?

For families? For communities? For the nation?

- How will this trend affect individual lives personally and professionally?
- How does multigenerational caring affect family finances?

A **family** consists of a group of interacting individuals related by blood, marriage, cohabitation, or adoption who interdependently perform relevant functions by fulfilling expected roles. Relevant family functions include practices and values placed on health. Family health practices, whether effective or ineffective, encompass activities performed by individuals or families as a whole to promote health and prevent disease. How well families complete developmental tasks and how well families, including individuals within a family, generate health-promoting behaviors determine a family's potential for enhancement of family health practices.

How family members relate to one another influences their understanding of behavior, which is demonstrated in the family's structural, functional, communicational, and developmental patterns (Glover & Justis, 2015). Families provide the structure for many health-promotion practices; therefore family assessment informs health-promotion and disease-prevention planning. Within families, children and adults are nurtured, provided for, and taught about health values by word and by example. Family members first learn to make choices to promote health within the family structure (Table 7-1). Appreciating how families make decisions and encouraging family participation in all aspects of care from acute care to health promotion helps families and individuals acquire new behaviors (Parkinson et al., 2016).

TABLE 7-1

Variety of Family Structures

Configuration	Positions in Family
Single parent	Mother or father, sons(s), daughter(s)

(separated, divorced, or widowed)	
Unmarried single parent (never married)	Mother or father, sons(s), daughter(s)
Unmarried cohabitating couple	Two adults living together in a long-term relationship that resembles marriage
Unmarried parents	Two adults, sons(s), daughter(s)
Commune family	Mothers, fathers, adults, shared son(s), daughters(s) living together
Stepparents	Adults with son(s), daughter(s) from previous marriage
Adoptive family	Adults who provide a permanent home to son(s) and/or daughter(s) through a legal process
Family of choice	Adults with selected partners and family members
Married couple	Two cohabitating adults living in a recognized legal union
Same sex couple	Two persons of the same gender sharing an intimate, romantic, or sexual relationship
Married parents	Mother and father, son(s), daughter(s)
Nuclear family	Mother and father, son(s), daughter(s)
Gay, lesbian, transgender family	Adults and children living together with one or more members of the group who identifies as gay, lesbian, or transgender
Immigrant family	Adults and children living together with one or more members of the group who is foreign born
Biracial or multiracial family	Mother, father, adults, or children include two or more races
Transracial family	Mother, father, adults, or children include at least one member who is born of one race and decides to represent themselves as another race
Blended family	Mother, father, adults, or children represent members of from previous unions
Joint-custody family	Adults living with children who are legally awarded to both biological parents
Conditionally separate families	A family member is separated from the family but remains a significant member of the family (military service, incarceration, distant employment, hospitalization)
Extended family	Significant family members beyond the nuclear family that may include grandparents, aunts, uncles, and other adults who live nearby or in one household
Foster family	Adults, serving as state-certified caregivers, for children placed into a ward, group home, or private home
Grandparent(s)	Grandchildren, son(s) and/or daughter(s) Grandmother and/or grandfather

Modified from Brown, S. L., Manning, W. D., & Payne, K. K. (2016). Family structure and children's economic well-being: Incorporating same-sex cohabiting mother families. *Population Research and Policy Review*, *35*(1), 1–21; Edwards, J. O. (2009). *The many kinds of family structures in our communities.* https://www.scoe.org/files/ccpc-family-structures.pdf.

Families influence children's lifestyle choices. *Healthy People 2020* views families in the United States as a means of providing important opportunities for health promotion and disease prevention (US Department of Health and Human Services, 2015). Through family planning, parents assume the responsibility of caring for their children. Prenatal care and breastfeeding give infants a healthy start. Nutritious diets support physical growth and development. Children

first observe and learn behaviors within their family. Patterns of nutrition, activity, oral hygiene, and coping develop at early ages, supported by the example of family members. Patterns of alcohol consumption and tobacco use are similarly established within families. Learning about human development fosters a healthy self-concept, including positive awareness of the family member's sexuality. Promoting self-esteem and reinforcing positive behaviors also strengthen the health of children. Primary care providers support positive behaviors by offering family members scientifically sound health-promotion and clinical preventive services, such as anticipatory guidance for developmental tasks, immunizations, screening for early detection, and appropriate counseling.

This chapter uses **family theory**, **systems theory**, **developmental theory**, and **risk-factor theory** to guide the nursing process with families. The 11 functional health patterns described in Chapter 6 establish the structure for interview questions during data collection. The analysis phase of the nursing process categorizes these data within stages of family development, and from the analysis, nursing diagnoses are formulated. **Family health status** is considered functional, potentially dysfunctional (potential problem), or dysfunctional (actual problem) (Gordon, 2016). The planning phase begins when family goals and objectives are stated. The family, the nurse, or another health professional facilitates implementation. Later in this chapter, four types of interventions for health promotion and disease prevention are discussed: increasing knowledge and skills; increasing strengths; decreasing exposure to risks; and decreasing susceptibility. Nurses assume various roles throughout the stages of family development, and these roles are also presented. Evaluation of a family plan considers outcomes that are specific, objective, and measurable and that rely on the family's subjective interpretation of concerns and probability of success, as well as that at the population level (Maurer & Smith, 2014).

The Nursing Process and the Family

The nursing process when promoting the health of families includes the family as a group and the interactions among family members. The National Center on Parent, Family, and Community Engagement (NCPFCE) views the entire family as the participant that guides assessment from a holistic framework (NCPFCE, 2015). Partnerships with families begin with an assessment (NCPFCE, 2015). The home is a natural environment for health-promotion encounters, although the process may occur in other settings as well. Different age groups (infants, children, and older adults) are likely to be present in the home. Nurses observe physical surroundings firsthand during home visits. For example, household safety hazards are observed directly. Nurses also monitor family unit rituals, roles, and interpersonal interactions. Generally the nurse contacts the family and establishes an appointment time for visiting the family. Including each family member in the visit provides a broad perspective. During visits, the nursing process develops mutually with families; it is not a treatment done for the family. Families collaborate with nursing in all phases of the process. Guidelines for home visits are presented in Box 7-1.

Box 7-1

Guidelines for Home Visits to Promote Health and Prevent Disease

Planning the Visit

- Make arrangements with the family.
- Study information regarding the family from agency records, referral forms, and other sources.
- Contact family and state the purpose of the visit.

- Obtain appropriate supplies and teaching aids for visits.

Making the Visit

- Offer an introduction and explain the purpose of the visit.
- Establish rapport.
- Show respect. Include all family members in the discussion.
- Identify the family's request for assistance.
- Understand the situation from the family's perspective.
- Identify appropriate activities for health promotion and disease prevention.
- Identify how the home visit is to be financed.
- Make a contract with the family that states specific goals and objectives that the family wants to reach.
- Think about safety before and during the visit.
- Identify and respond to health and home safety issues.
- Terminate the visit with specific instructions and information about the next visit: when it will occur, what will happen, who will be present, and what the family must accomplish before then.
- Carry through promptly on agreements made.
- Record notes promptly.

Modified from Alaska Parent Information and Resource Center. (n.d.). *Home visiting guidelines.* http://akpirc.org/wp-content/uploads/2011/04/Home-visiting.pdf; Vanderbilt Kennedy Center. (n.d.). *Home visits.* http://kc.vanderbilt.edu/kennedy_files/HomeVisitsTipsandResourcesJune2011.pdf.

Comprehensive family assessment provides the foundation to promote family health (NCPFCE, 2015). Several factors influence family assessment, such as nurses' perceptions about family constitution; theoretical knowledge; norms; standards; and communication abilities during visits. In addition to factors that pertain to the nurse, familial factors also influence assessments, such as family cooperation, mutual agreement to work toward goals, and family ability to recognize the relevance of health-promotion plans. Useful health-promotion family assessments involve listening to families, engaging in participatory dialogue, recognizing patterns, and assessing family potential for active, positive change (NCPFCE, 2015).

The assessment phase of the nursing process seeks and identifies information from the family about health-promotion and disease-prevention activities. To obtain this information, nurses follow family progress through developmental tasks and identify strengths in the family's ability to generate behaviors associated with disease prevention. The approaches considered in this chapter include the developmental framework, strength-based assessment, and the risk-factor estimate. Developmental phases for families as proposed by Duvall and Miller (Duvall, 1988; Duvall & Miller, 1985), strength-based assessment using a standardized tool (e.g. Canadian Family Assessment Tool) proposed by Wright and Leahy (2013), and risk-factor estimates delineated by *Healthy People 2020* can be used to guide nurses through the steps of the nursing process when they are working with families.

The Nurse's Role

Nurses collaborate with families using a systems perspective to understand family interaction, family norms, family expectations, effectiveness of family communication, family decision-making, and family coping mechanisms. The nurse's role in health promotion and disease prevention includes the following tasks:

- Become aware of family attitudes and behaviors toward health promotion and disease prevention.

- Act as a role model for the family.
- Collaborate with the family to assess, improve, enhance, and evaluate family health practices.
- Assist the family in growth and development behaviors.
- Assist the family in identifying risk-taking behaviors.
- Assist the family in decision-making about lifestyle choices.
- Provide reinforcement for positive health-behavior practices.
- Provide health information to the family.
- Assist the family in learning behaviors to promote health and prevent disease.
- Assist the family in problem-solving and decision-making about health promotion.
- Serve as a liaison for referral or collaboration between community resources and the family.

Nurses use family theoretical frameworks to guide, observe, and classify situations. Nursing roles for families in various stages of development are presented in Table 7-2.

TABLE 7-2

Possible Nurse's Roles in Health Promotion and Disease Prevention Through Stages of Family Development

Stage	Possible Nursing Role
Couple	Counselor on sexual and role adjustment Teacher of and counselor on family planning Teacher of parenting skills Coordinator for genetic counseling Facilitator in interpersonal relationships
Childbearing family	Monitor of prenatal care and referrer for problems of pregnancy Counselor on prenatal nutrition Counselor on prenatal maternal habits Emotional support for amniocentesis Counselor on breastfeeding Coordinator with pediatric services Supervisor of immunizations Referrer to social services Assistant in adjustment to prenatal role
Family with preschool or school-age children	Monitor of early childhood development; referrer when indicated Teacher of first-aid and emergency measures

	Coordinator with pediatric services Counselor on nutrition and exercise Teacher of dental hygiene Counselor on environmental safety in home
Family with adolescents	Facilitator in interpersonal relationships Teacher of risk factors to health Teacher of problem-solving issues regarding alcohol, smoking, diet, and exercise Facilitator of interpersonal skills with adolescents and parents Direct supporter of, counselor on, or referrer to mental health resources Counselor on family planning Referrer for sexually transmittable disease
Family with young or middle-aged adults	Participant in community organizations involved in disease control Teacher of problem-solving issues regarding lifestyle and habits Participant in community organization involved in environmental control Case finder in home and community Screener for hypertension, Pap test, breast examination, mental health, and dental care Counselor on menopausal transition
Family with older adults	Facilitator of interpersonal relationships among family members Referral for work and social activity, nutritional programs, homemakers' services, and nursing home Monitor of exercise, nutrition, preventive services, and medications Supervisor of immunization Counselor on safety in home Counselor on bereavement

Family Theories and Frameworks

Family theory stems from a variety of interrelated disciplines (Atkin et al., 2015). Family systems theory explains patterns of living among the individuals who comprise family systems. In systems theory, behaviors and family members' responses influence patterns. Meanings and values provide the vital elements of motivation and energy for family systems. Every family has its unique culture, value structure, and history. Values provide a means for interpreting events and information, passing from one generation to the next. Values usually change slowly over time. Families process information and energy exchange with the environment through values. For example, holiday food traditions may be changed slightly by a daughter-in-law, whose own daughter may then adjust the traditional recipe within her own nuclear family.

System boundaries separate family systems from their environment and control information flow. This characteristic forms a family internal manager that influences and defines interactions and relationships with one another and with those outside the family system. The family forms a unified whole rather than the sum of its parts—an integrated system of interdependent functions, structures, and relationships. For example, one drug-dependent individual's health behavior influences the entire family unit.

Living systems are open systems. As living systems, families experience constant exchanges of energy and information with the environment. Change in one part or member of the family results in changes in the family as a whole. For example, loss of a family member through death changes roles and relationships among all family members. Change requires adaptation of every family member as roles and functions assume new meanings. Changes families make are incorporated into the system.

When the system is the family, issues can be clarified by family processes, communication interaction among family members, and family group values. In Bowen's family systems theory, birth order is

considered an important determinant of behavior. In addition, family patterns of behavior differentiate one family from another (Vedanthan et al., 2016; Vess & Lara, 2016). When an individual family member expresses behaviors that differ from the learned family pattern, differentiation of self occurs. Interaction among family members and the transmission of these interaction patterns from one generation to the next provide the framework for the family systems approach (Rothenberg et al., 2016).

The framework for health promotion introduced by Pender and colleagues (2014) recognizes the family as the unit of assessment and intervention because families develop self-care and dependent-care competencies; foster resilience among family members; provide resources; and promote healthy individuation within cohesive family structures. Furthermore, because the family often provides the structure for implementation of health promotion, family assessment becomes an integral tool to foster health and healthy behaviors (Pender et al., 2014).

The Family From a Developmental Perspective

Building on Erikson's (1998) theory of psychosocial development, Duvall and Miller (1985) identified stages of the family life cycle and critical **family developmental tasks**. Although Duvall's classification has been criticized for its middle class homogeneity and lack of diversity in family forms, this conceptual model helps to anticipate family events and has formed the basis for more contemporary developmental models (Duvall & Miller, 1985). Knowing a family's composition, interrelationships, and particular life cycle helps nurses predict the overall **family pattern**. Box 7-2 lists characteristics of healthy families. From Duvall's perspective, most families complete these basic family tasks. Each family performs these tasks in a unique expression of its personality. Progression through the stages occurs in a linear fashion; however, regression may occur and families may experience tasks in more than one stage at a time (Duvall & Miller, 1985). Specific tasks arise as growth responsibilities during family development. Failure to accomplish a developmental task leads to negative consequences. For example, intimate partner violence or child abuse or neglect may result in intervention by police, welfare, health department, or other agencies. Life cycle tasks build upon one another. Success at one stage is dependent on success at an earlier stage. Early failure may lead to developmental difficulties at later stages.

Box 7-2

Characteristics and Indicators of Healthy Families

Nurturing RELATIONSHIPS

- Maintains trust traditions and shares quality time.
- Communications are open and members listen to each other.

Establishing ROUTINES

- Maintains routines that promote health patterns of nutrition, hygiene, rest, physical activity, and sexuality.
- Maintains routines to promote safety and injury prevention; health protection; disease prevention; smoking and alcohol or substance abuse; and/or violence.
- Establishes patterns to promote mental health: interacting, communicating, and expressing affection, aggression, sexuality, and similar interactions.

Maintaining EXPECTATIONS

- Maintains morale and motivation, rewarding achievement, meeting personal and family crises, setting attainable goals, and developing family traditions, loyalties, and values.

ADAPTING to challenges

- Evolves during crises and respects each member of the group.
- Promotes strategies to make decisions about health and illness.

Connecting to COMMUNITY

- Family table time and conversation occur regularly.
- Members act as interactive caregivers across the life span to socialize children and adolescents, to participate in the community, and to support members as they age.

Modified from Search Institute. (2016). *Family strengths.* http://www.search-institute.org/research/family-strengths.

As families enter each new developmental stage, transition occurs. Families move through new stages as a result of events ranging from marriage (heterosexual, homosexual), gay and lesbian relationships, childbirth, single-led families, joint custody, or remarried families; to adolescents maturing into young adults and leaving the home; to the aging years.

Each new developmental stage requires adaptation with new responsibilities. Concurrently, developmental stages provide opportunities for families to realize their potential. Nurses anticipate change through analysis of progress through each stage. Each new stage presents opportunities for health promotion and intervention. Family developmental stages, although reflective of traditional nuclear families and extended family networks, also apply to nontraditional family configurations (Coyne et al., 2016; Edwards, 2009). A family systems approach addresses the interaction of these

multiple family configurations. For example, couples may marry and bring children from a previous marriage to a blended family that works toward achieving developmental tasks of couples along with family stages for the children. Both the couple and their children possess values and beliefs from the past that must integrate within the present union. Childless couples present developmental tasks that are different from those proposed for couples with children. One family conceptual model proposed by Vedanthan and colleagues (2016) illustrates the multiple connections among interdependence among family systems, shared environment, parenting style, caregiver perceptions, and genomics to promote cardiovascular health.

Nurses collect data to determine progress toward family developmental task attainment during the family assessment. Use of assessment tools that include gathering factors that strengthen and protect the family such as the Canadian Family Assessment Tool and the Family Development Matrix used in California provides more robust information (Harper Browne, 2014). These newer assessment tools focus on the assessment of family assets and social network resources that families currently use. These kinds of assessments intend to build on strengths at particular developmental stages to promote healthy family environments. Assessment of family developmental stages entails use of guidelines to analyze progress toward developmental tasks, family growth, and health-promotion needs.

The Family From a Structural-Functional Perspective

Families consist of both structural and functional components. **Family structure** refers to family composition, including roles and relationships, whereas **family function** consists of processes within systems as information and energy exchange occurs between families and their environment.

The Family From a Risk-Factor Perspective

Family risk factors can be inferred from lifestyle; biological factors; environmental factors; social, psychological, cultural, and spiritual dimensions; and the health care system. As outlined in the Frank Thompson case study in Chapter 1, lifestyle habits such as overeating, drug dependency, high sugar and cholesterol intake, and smoking influence health outcomes. Biological risk factors may include the elements of genetic inheritance, congenital malformation, and mental retardation. To fully explore environmental risk factors that influence family function, nurses explore work pressures, peer pressure, stress, anxieties, tensions, and air, noise, or water pollution. Social and psychological dimensions such as crowding, isolation, or rapid and accelerated rates of change are areas to consider when nurses are assessing family risk factors. Cultural and spiritual aspects may include traditions of preventing illness such as daily prayer and meditation practices. Finally, health care system factors such as overuse, underuse, inappropriate use, or accessibility are considered in the family risk assessment.

To reduce risk factors, nurses help families focus on influencing health behaviors of their members. Society glamorizes many hazardous behaviors through advertising and mass media promotions that minimize negative health consequences. Families influence their members to weigh the consequences of risk-taking behavior. Awareness of risk factors may prompt families to reduce modifiable risk factors. Healthy behavior, including use of preventive health care services, is a significant area of family responsibility.

Traditionally, epidemiology has used levels and trends of mortality and morbidity rates as indirect evidence of health. Data such as infant mortality rates, stillbirth rates, and leading causes of death have long been used as indicators of collective community health. Healthy family functioning links the family life cycle stages with specific risk

factors. Epidemiology often describes a disease association in terms of risk. Health risks can be physiological or psychological. Physiological risks arise from genetic background, whereas psychological risks include those related to low self-image. Risks also arise from environmental considerations, including the physical environment and socioeconomic condition (Freudenberg et al., 2011). Risk-factor theory considers families a pivotal part of the environment and also an important support system used to decrease health risks for individuals. As young family members mature developmentally and seek more independence from the family, peers may influence risk to compete with family values.

Risk estimates calculate differences between two groups: one with the risk factor and one without. The frequency of deaths, illnesses, or injuries with some specific risk factor compared with those for another group without the risk factor, or the population as a whole, determines the risk estimate. Some diseases (e.g., sickle cell anemia in Black-American families and Tay-Sachs disease in families of Ashkenazi Jewish descent) occur more frequently in certain families and can be identified by carrier screening (Azimi et al., 2016). Other recessive genetic disorders (e.g., cystic fibrosis and Gaucher disease) have decreased in incidence with prenatal carrier screening with genetic counseling in couples with suspect family histories (Azimi et al., 2016). Azimi and colleagues (2016) compared current strategies that target specific high-risk families to next-generation DNA sequencing (NGS) that provide high-level sensitivity and specificity for carrier screening. They developed a mathematical model to screen individuals for 14 recessive disorders commonly recommended for screening in targeted populations. The mathematical model provides support to transition from traditional lower-accuracy genotyping to more accurate NGS techniques focused on the most prevalent disorders (Azimi et al., 2016). Other diseases such as iron-deficiency anemia may not be attributed to a specific genetic background. The natural history of a chronic disease predisposes family members to greater risk, but specific causes may be difficult to identify. Well siblings, particularly adolescents, may be affected. Larsen (2016)

describes nine phases that individuals and families may experience as they progress through chronic illness adaptation from the time before the disorder is recognized through a stable adjustment phase to the final relinquishment of life interest and activities.

The probabilities of risk change may also change depending on the family's activities in health promotion and disease prevention. Stages of family development are used to classify risk factors. Age-specific developmental stages, along with their associated age-specific health risks, are given in Table 7-3, which displays periods during which families become most sensitive to certain problems, with corresponding key times for health promotion and disease prevention. The risk behaviors highlighted include tobacco and alcohol use, faulty nutrition, overuse of medications, fast driving, stress, and relentless pressure to achieve. Habits learned in family settings help to develop individual lifestyle behaviors. In fact, 5 habits—nutrition, smoking, exercise, alcohol use, and stress—affect at least 7 of the 10 leading causes of death listed in *Healthy People 2020* (USDHHS, 2015). See Box 7-3: *Healthy People 2020* for selected objectives related to families.

TABLE 7-3

Family Stage: Specific Risk Factors and Related Health Problems

Stage	Risk Factors	Health Problems
Beginning childbearing	Lack of knowledge of family planning Adolescent marriage Lack of knowledge concerning sexual and marital roles and adjustments Low-birth-weight infant Lack of prenatal care Unmarried status First pregnancy before age 16 years or after age 35 years History of hypertension and infections during pregnancy Rubella, syphilis, gonorrhea, and AIDS Genetic factors Lack of safety in home	Premature baby in family Birth defects Birth injuries Accidents Sudden infant death syndrome (SIDS) Sterility Pelvic inflammatory disease Fetal alcohol syndrome Mental retardation Injuries Birth defects Underweight
Family with school-age children	Working parents with inappropriate use of resources for child care Generational pattern of using social	Behavior disturbances Speech and vision problems Communicable diseases

	agencies as way of life Multiple, closely spaced children Low family self-esteem Children used as scapegoats for parental frustration Repeated infections, accidents, or hospitalizations Parents immature, dependent, and unable to handle responsibility Unrecognized or unattended health problems Strong beliefs about physical punishment Toxic substances unguarded in the home	Dental caries School problems Learning disabilities Injuries Chronic diseases Homicide Violence
Family with adolescents	Health disparities Lifestyle and behavior patterns leading to chronic disease Lack of problem-solving skills Family values of aggressiveness, competition, rigidity, and inflexibility Daredevil risk-taking attitudes Conflicts between parents and children Pressure to live up to family expectations	Violent deaths Unwanted pregnancies Sexually transmitted diseases
Family with middle-aged adults	Hypertension Smoking High cholesterol levels Genetic predisposition Use of oral contraceptives Geographical area or occupation Residence	Cardiovascular disease, principally coronary artery disease and cerebrovascular accident (stroke) Diabetes Accidents Homicide Abnormal fetus Mental illness Periodontal disease and loss of teeth
Family with older adults	Age Drug interactions Metabolic disorders Pituitary malfunctions Cushing syndrome Hypercalcemia Chronic illness Retirement Loss of spouse Past environments and lifestyle Lack of prevention for death	Mental confusion Reduced vision Hearing impairment Hypertension Acute illness Infectious disease Influenza Pneumonia Injuries such as burns and falls Death without dignity

Risks of poverty, abuse, neglect, substance abuse, poor nutrition, denial behavior, and socioeconomic status affect all ages. Depression, suicide, cancer, overweight, obesity, sedentary lifestyles, and respiratory distress syndrome affect most age groups. Therefore, these items have been excluded from the table.

Box 7-3

Healthy People 2020

Selected Examples of National Health-Promotion and Disease-Prevention Objectives for Families

BDBS-2 (Developmental) Increase the proportion of persons with a diagnosis of hemoglobinopathies and their families who are referred for evaluation and treatment.

BDBS-3 (Developmental) Increase the proportion of persons with hemoglobinopathies who receive care in a patient/family-centered medical home.

EMC 2.3 Increase the proportion of parents who read to their young child.

WS-13 Reduce household food insecurity and in doing so reduce hunger.

EH-15 Increase the percentage of new single-family homes constructed with radon-reducing features, especially in high radon–potential areas.

Family Planning Objectives

FP-1 Increase the proportion of pregnancies that are intended.

FP-2 Reduce the proportion of females experiencing pregnancy despite use of a reversible contraceptive method.

FP-3 Increase the proportion of publicly funded family planning clinics that offer the full range of FDA-approved methods of contraception, including emergency contraception, on-site.

FP-4 (Developmental) Increase the proportion of health insurance plans that cover contraceptive supplies and services.

FP-5 Reduce the proportion of pregnancies conceived within 18 months of a previous birth.

FP-6 Increase the proportion of females or their partners at risk of unintended pregnancy who used contraception in the most recent sexual intercourse.

FP-7 Increase the proportion of sexually active persons who received reproductive health services.

FP-8 Reduce pregnancy rates among adolescent females.

FP-9 Increase the proportion of adolescents aged 17 years or younger who have never had sexual intercourse.

FP-10 Increase the proportion of sexually active persons aged 15 to 19 years who use condoms to both effectively prevent pregnancy and provide barrier protection against disease.

FP-11 Increase the proportion of sexually active persons aged 15 to 19 years who use condoms and hormonal or intrauterine contraception to both effectively prevent pregnancy and provide barrier protection against disease.

FP-12 Increase the proportion of adolescents who received formal instruction on reproductive health topics before they were 18 years old.

FP-13 Increase the proportion of adolescents who talked to a parent or guardian about reproductive health topics before they were 18 years old.

FP-15 Increase the proportion of females in need of publicly supported contraceptive services and supplies who receive those

services and supplies.

G-1 Increase the proportion of women with a family history of breast and/or ovarian cancer who receive genetic counseling.

DH-20 Increase the proportion of children with disabilities, from birth through age 2 years, who receive early intervention services in home or community-based settings.

Gordon's Functional Health Patterns: Assessment of the Family

Gordon's (2016) 11 functional health patterns help organize basic family assessment information. Patterns form the standardized format for family assessment using a systems approach with emphasis on developmental stages and risk factors. Assessment includes evaluation of dysfunctional patterns within families, with corresponding details in one or more of the other interdependent patterns (see Chapter 6).

The presence of risk factors predicts potential dysfunction. Developmental risk and risk arising from dysfunctional health patterns increase whole family risk (see Table 7-3). Gordon (2016) interprets risk states as potential problems. To formulate nursing diagnoses, nurses identify problems along with their associated and etiological factors. Influencing factors may precede or occur concurrently with the problem and are used to plan care. Interventions aim to modify influencing factors to promote positive change.

Family history begins with the health perception–health management pattern. Exploring issues within this pattern first provides an overview to help locate where problems exist in other patterns and to determine which problems require more thorough assessment. Interviewing from the family's perspective helps families define situations. The roles-relationships pattern defines family structure and function. The remaining nine patterns address lifestyle indicators.

Health Perception–Health Management Pattern

Characteristics of family health perceptions, health management, and preventive practices emerge with assessment of the health perception–health management pattern. The National Survey of Children's Health (http://www.childhealthdata.org/) and other data sources contribute

additional information to help identify health-promoting behaviors of families. Data collected in the Survey of Children's Health include information about the frequency of family meals; attendance at religious services; characteristics of parental relationship with children; parental coping abilities while parents are raising children; and methods for handling family disagreements. The intent of the survey is to provide a data source to explore research questions related to *Healthy People 2020* and the variables correlated with drug use. However, such data have also been associated with eating disorders and risk behaviors other than drug use. These assessment indicators also provide data to guide the remaining functional health pattern assessment. Patterns overlap, and findings in one pattern may encourage further assessment in another pattern. The following are some research questions that concern family health promotion:

- What are the chief concerns of parents and other adults in the household about their children's development, learning, and behavior?
- How do children's health status and the health practices (physical activity and smoking behavior) of the adults compare?
- What health-related behaviors, such as eating three meals a day at regular times, eating breakfast every day, exercising for a minimum of 2 or 3 days a week, sleeping for 7 to 8 hours each night, and abstaining from smoking, are practiced by the family?
- How safe are homes, schools, and neighborhoods from the perspective of the family?

Health practices differ from family to family. Families identify and perform health-maintenance activities based on their beliefs about health. Exploration during the assessment also includes the following areas:

- What is the family's philosophy of health? Does each family member hold similar beliefs? Do family members practice what they believe?
- In what negative behaviors or lifestyle practices, such as smoking, alcohol, and drug abuse, do the family engage?
- What chronic disease risk behaviors are exhibited within the family?

- Are risk factors present for infections, such as lack of immunization, lack of knowledge of transmittable diseases, and poor personal hygiene?
- Are risk factors for bodily injury, accidents, or substance abuse present in the home?
- Do older adult members know what medications they are taking and the reasons for their using them?
- Does the family discard outdated medications or those not used?
- What unattended health problems exist?
- Is there a history of repeated infections and hospitalization?
- Is the home understimulating or overstimulating?
- Where does the family obtain health and illness care?
- Is the family engaged in a dental program?
- How does the family describe previous experiences with nurses and other health care professionals?

Nutritional-Metabolic Pattern

The nutritional-metabolic pattern depicts characteristics of the family's typical food and fluid consumption and metabolism (Gordon, 2016). Included in it are growth and development patterns, pregnancy-related nutritional patterns, and the family's eating patterns. Risk factors for obesity, diabetes, anorexia, and bulimia are identified.

Dietary habits, learned within the family context, involve behavioral patterns central to daily life. Keeping a diary of intake for a week is a useful strategy for assessing family food and fluid intake patterns. Assessment notes both meals shared with the whole family as well as additional consumption by individuals. Recent research provides evidence that family meal sharing is associated with healthier eating habits. For example, Utter and colleagues (2013) report that family meal sharing in their sample of New Zealand adolescents (n = 9101) was positively associated with higher well-being scores, lower depression scores, and fewer risk-taking behaviors. In a follow-up report of this same population, Utter and

colleagues (2016) found the same positive associations with better nutritional indicators (fruit and vegetable intake), better mental health indicators (fewer depressive symptoms), and stronger family connections in adolescents who knew how to prepare food compared with those adolescents without the cooking abilities. However, the adolescents with cooking ability were more likely to have higher body mass index.

Exploration during nutrition pattern assessment includes the following areas:

- What kinds of foods are typically consumed?
- Who eats together at mealtimes?
- How is food viewed (reward/punishment)?
- Is there adequate storage and refrigeration?
- How is food purchased?
- How is food prepared?
- Who prepares food?

Elimination Pattern

The elimination pattern describes characteristics of regularity and control of the family's excretory functions (Gordon, 2016). Bowel and bladder function and environmental factors such as waste disposal in the home, neighborhood, and community that influence family life are considered in this pattern.

Questions are phrased according to the age-specific developmental stage of the family. For example, when the nurse is attempting to determine whether there is a problem in the preschool stage, it would be appropriate to ask whether the child is being toilet trained. In families with adolescents, the nurse may ask how often individuals have bowel movements and whether there have been any changes from usual patterns. The nurse may ask older adult members whether they have any problems with constipation. Issues that particularly concern older adults include constipation, diarrhea, polyuria, and incontinence, as well as use of antacids and constipation-relieving

agents and strategies. The nurse evaluates whether use of these strategies is appropriate or possibly contributing to poor health.

Activity-Exercise Pattern

The activity-exercise pattern represents family characteristics that require energy expenditure (Gordon, 2016). The nurse reviews daily activities, exercise, and leisure activities. Families create settings for individual members to be physically active, sedentary, or apathetic toward physical activity. The quantity of sedentary activities such as television and video game screen time is explored.

Exploration during assessment of this pattern includes the following areas:

- How does the family exhibit its beliefs about regular exercise and physical fitness being necessary for good health?
- What types of daily activities include physical exercise and who does what with whom?
- What are the television viewing habits of children?
- How are other screen-viewing activities (computers, video games) incorporated into the daily routines?
- How often do children exercise?
- How are these activity and exercise factors related to children's health?
- What does the family do to have fun (Figure 7-1)?

FIGURE 7-1 Family outings can be **(A)** leisurely and restful or **(B)** adventurous and exciting.

Sleep-Rest Pattern

Rest habits characterize the sleep-rest pattern (Gordon, 2016). Without the restorative function of sleep, individuals exhibit decreased performance, bad temper, and decreased stress tolerance, and may rely on alcohol or other chemicals to induce sleep. Regular, sufficient sleep patterns are linked to better mental status, including learning and decision-making. Most families have sleeping patterns, although in some families these patterns may not be readily apparent. It is important to elicit the data about sleep and rest from the family's perspective.

Assessment of the sleep-rest pattern includes the following:

- What are the usual sleeping habits of the family?
- How suitable are they to the age and health status of the family members?
- What are the usual hours established for sleeping?
- Who decides when and how children go to sleep?
- Do family members take naps or have other regular means of resting or relaxing?
- How early does the family rise? What are the patterns related to bedtime and rising?

- Do all family members have the same general sleep-rest pattern?
- Is there a family member with sleep disruption?

Cognitive-Perceptual Pattern

The cognitive-perceptual pattern identifies characteristics of language, cognitive skills, and perception that influence desired or required family activities (Gordon, 2016). Specifically, this pattern concerns how families access information to make decisions, how concrete or abstract the thought processes are, and whether the decisions focus on present or future issues. Decision-making in families is associated with power in family functioning. Highly educated families usually have greater repertoires for problem-solving. Power and ability to solve problems are linked to leadership; family leaders must be acknowledged if nursing interventions are to be implemented.

Cognitive-perceptual pattern assessment includes the following:

- How does the family access and interpret information, especially about health (e.g., newspaper, books, computer, television, or radio)?
- What are the usual family reading patterns and strategies used for ongoing learning (e.g., continuing education programs)?
- What kinds of materials does the family read to the children?
- How does the family usually make decisions about health promotion and disease prevention?
- How do family members contribute to the decision-making process?
- How knowledgeable is the family about risk factors and developmental milestones?
- How are choices made regarding lifestyle?
- How knowledgeable are family members about correct information?
- How do family members acquire information?
- How accurate are the information sources used to make health-promotion choices?
- How do family members describe whether their health behavior is constructive or destructive?

- How do family members recognize signs and symptoms of deteriorating health?
- How do family members decide when medical attention is necessary?
- Who makes the decisions about when to seek health care?
- What factors contribute to delays from the time of onset to the time of treatment?
- How long do families wait before seeking care?
- What are some of the cues that signal to families that care is needed?
- How is professional care accessed?
- What type of health care is generally used health maintenance for immunizations (well-child care or emergency/urgent care facilities)?
- How are decisions made about the use of over-the-counter medications or the use of alternative or traditional health practices?

Self-Perception–Self-Concept Pattern

The self-perception–self-concept pattern identifies characteristics that describe the family's self-worth and feeling states (Gordon, 2016). Rapport between the family members and the nurse facilitates disclosure. Families have perceptions and concepts about their image, their status in the community, and their competencies as a family unit. Families manifest these perceptions through shared aspirations, values, expectations, fears, successes, and failures. Relationships in families determine the amount of sharing that occurs. Situations affecting one member influence perceptions of the entire family group. How each member describes the family often gives clues to the family self-concept.

Exploration during assessment includes the following:

- How is this family similar to or different from other families?
- How does this family perceive itself to be similar to and different from other families?
- What special assets does each member contribute to the family?

- What changes would each member like to see occur in the family?
- What kinds of feelings do family members have for each other?
- Describe the general tone of feelings in the family. Is the tone indifferent, secretive, angry, or open?
- How does the family think it assimilates into the neighborhood and community?
- How does the family handle stress and crisis situations?
- How does the family experience changes in the way it feels about itself?
- How does the family describe the events that led to a change?

Roles-Relationships Pattern

The roles-relationships pattern identifies characteristics of family roles and relationships (Gordon, 2016). Both structural and functional aspects of the family are assessed. Structural aspects of families include each member's name, age, sex, education, occupation, and role in the family. Traditionally, families have been described as nuclear and extended. The traditional nuclear family consists of husband, wife, and children, with an extended family that would include aunts, uncles, cousins, and grandparents. Today there are many varieties of nuclear and extended families. Edwards (2009) describes various contemporary family structures: traditional nuclear family, extended families, single-parent families, stepfamilies, cohabiting families, gay and lesbian families, grandparent-headed families, foster families, and fragmentary families. Traditional nuclear family structure has been influenced by societal changes, such as the women's movement, employment of mothers, divorce, and remarriage. Exploration of family origin and genetic heritage completes family identification data collection. Cultural practices in the home may or may not reflect the family's genetic heritage; therefore it is important to explore the diversity of cultural and ethnic practices during the family assessment (Andrews & Boyle, 2015).

The American Academy of Pediatrics regards the family as the most

enduring link to health for children. For example, findings from the Early Childhood Longitudinal Study, Birth Cohort (n = 5000) maternal health behaviors at each phase of early development (9 months, 2 years, 4 years, 5 years) indicated the importance of the mother-child relationship in health promotion (Prickett & Augustine, 2016). The US Census Bureau (2014) released information in 2011 from the *Annual Report of Families and Living Arrangements*. The proportion of young adults aged 15 to 34 years living in their parents' homes increased from 14% in 2005 to 19% in 2011 and has extended beyond the economic recession. In regard to children aged 5 to 15 years, 69% live with both parents. Children living with only one parent are more likely to live with their mother. Grandparents live in 10% of the homes that have children younger than 18 years. The proportion of children with stay-at-home mothers decreased from 24% in 2007 to 23% in 2011. There is also an overall trend of increasing proportions of individuals living alone in their home, increasing from 13% in 1960 to 28% in 2011.

Schoon and colleagues (2012) suggest that children in the United Kingdom experiencing poverty for the first 5 years of life are at higher risk of impaired cognitive development than those who do not experience poverty. These data indicate the need to identify family structure for poverty-related factors to determine those families at risk and effectively intervene (see Figures 7-1, 7-2, and 7-3). Family structure and function influence family stability and pose a challenge to the nurse in health promotion and disease prevention.

Divorce and remarriage involve a complex transition that requires the disintegration of one family structure and reorganization to another (Hiyoshi et al., 2015). How parents cope during situational crises, as well as after the divorce, is a significant variable in long-term individual and family adjustment. See the case study at the end of this chapter for the presentation of a stepfamily situation. Developmental levels of children, individual temperaments of children, and quality of environmental support for children all contribute to family response to crises. For example, Feise and Bost (2016) explore how families' responses impact obesity risk in children. They link family system

factors, such as family meal routines and distress during meals, with the biological risk of obesity.

A **family resilience** framework may be useful to promote strategies for prevention efforts aimed at strengthening families as they face life challenges. Masten and Monn (2015) describe an integrated method for understanding and promoting resilience in children and families. Family disruption has been associated with substance abuse and psychosocial maladjustment in adolescents and young adults. Family supports are associated with adherence, and substance abuse may decrease healthy social support systems. Moreover, both family dissolution and family disruption may be associated with substance abuse, alcohol consumption, and externalizing behaviors such as theft, property destruction, fighting, and assault (Masten & Monn, 2015). The current literature provides support for the importance of the roles-relationships patterns in the development of health-promoting behaviors (Gordon, 2016; Masten & Monn, 2015).

Family organization influences performance of health-promotion and disease-prevention functions. For example, a single parent without an extended family network may be in need of more community resources to help raise the children. A two-parent family living near its extended family may need less support to raise children, but family members may need to know about growth and developmental stages and immunization schedules. Individuals may experience a variety of family structures in one lifetime. A person may be part of a nuclear family as an infant, a single-parent family after the parents have divorced, a stepparent family after the mother or father has remarried, and an unmarried couple family when the person is one of two adults who share a household. The person brings the values and beliefs about health promotion and disease prevention that were practiced in previous unions to each new family configuration. Divergent values may result in conflicting expectations unless the new union forms a set of integrated values and beliefs. The current trend away from the nuclear family with the extended family may influence the general direction of the health care system and the strategies used to promote health with other family configurations.

Certain health-promotion issues are of particular concern to the nurse while he or she is assessing family health promotion and disease prevention. Violence is a health problem that threatens the integrity of all families. Alhusen and colleagues (2015) provide an overview of several studies reporting that the National Violent Death Reporting System lists a rate of 2.9 homicides per 100,000 live births. Often pregnancy-associated suicides involved intimate partner conflict attributable to the suicide, and almost half of the pregnancy-related homicides are related to family violence (Alhusen et al., 2015). According to Alhusen and colleagues (2015) these homicides outnumber the reported numbers of deaths from some of the common obstetrical causes. Furthermore, bullying contributes to violence issues that pertain to families. Bullying is addressed in *Healthy People 2020 Objectives* (USDHHS 2015). The measure used for this objective (IVP-35 Reduce bullying among adolescents) is the percentage of children bullied on school property during the 12 months before the survey (USDHHS, 2015). The midterm measure in 2013 (19.6%) was a 10% reduction since 2010 and moved toward the 2020 target of 17.9%. The role of the family dysfunction and support is linked to bullying behavior (Kann et al., 2013). Furthermore, bullying within families among siblings also occurs (Berry & Adams, 2016).

Family violence includes child abuse, spousal abuse, and elder abuse, with women being victimized more often during pregnancy. Death in pregnancy is often associated with domestic violence (Alhusen et al., 2015). Health promotion and violence prevention require a complex set of skills. Nurses use approaches to reduce violence-related injuries and deaths by acquiring the role of advocate and helping to eliminate victim blaming (Box 7-4: Research for Evidence-Based Practice). Explorations to assess families for health promotion and violence prevention may include the following:

Box 7-4

Research for Evidence-Based Practice

Twenty Latina women who had experienced domestic violence

participated in this mixed-methods single subject design. Participant journaling and one-on-one interviews with research assistants were included in the design. Data were collected at multiple intervals during the 5-week training period for *promotoras* (community health workers).

These women were all born outside the United States. Average age of 36 years and 10.6 years of completed education, employment in the service industry characterized the sample. Quantitative measures, interviews, and journals revealed that the training increased leadership competency.

These findings provide support for recognizing the contribution of *promotoras* to community and public health. These types of development programs may also empower the *promotoras* to continue their community participation and model their engagement within their communities for other women.

From Serrata, J. V., Hernandez-Martinez, M., & Macias, R. L. (2016). Self-empowerment of immigrant Latina survivors of domestic violence: A promotora model of community leadership. *Hispanic Health Care International*, *14*(1), 37–46.

- What formal positions and roles does each of the family members fulfill?
- What roles are considered acceptable and consistent within the family's expectations?
- What kind of flexibility in roles occurs when needed?
- What informal roles exist? Who plays informal roles and with what consistency?
- What purpose do the informal roles serve?
- How are the family social support networks associated with health and development?
- Who were the role models for the couples or single people as parents?
- Who were the role models for marital partners and what were their characteristics?
- How does the family manage daily living? How are the household

tasks divided?

- How are problems handled? How are problems with children handled?
- Who is employed outside the home?
- Who takes care of the children when both parents are employed outside the home?
- How does the family care for its ill members? How does it care for its older adult members?
- Are behaviors appropriate for family stages of development?
- Is decision-making allocated to the appropriate members?
- Does the family respond appropriately to its members' developmental needs?
- Is there fair distribution of tasks among family members?
- Is the family's emotional climate conducive to growth and development?
- Is there a connection between family and community crime?

In their study of 413 adolescents, Hardaway and colleagues (2016) provide evidence that family relationships protect adolescents from harm in violent communities. They report that interaction with the extended family and parental engagement act as resources for youth who are exposed to violence in their neighborhoods. These findings indicate that nurses working with families should encourage parents to maintain open communication within the family and that parents should enlist additional support from their extended family members as a larger network of positive influence for their children.

When this initial assessment reveals possible neglect, abuse, or violence, further assessment is warranted with a branched assessment that may include the following assessment parameters and questions:

- What cues are present to indicate chemical abuse?
- Who are the significant adult members of the household? (Determine the presence of a boyfriend/girlfriend.)

Nursing diagnoses and planning stem from a thorough assessment.

High-quality evidence-based intervention is based on this systematic approach to assessment. For example, quality intervention for victims of intimate partner violence can be planned in advance to promote the safety and well-being of the victims (Box 7-5: Quality and Safety Scenario).

Box 7-5

Quality and Safety Scenario

Domestic Violence: Intimate Partner Violence

If the person is still in the relationship:

- Think of a safe place to go if an argument occurs—avoid rooms with no exits (bathroom) or rooms with weapons (kitchen).
- Think about and make a list of safe people to contact.
- Keep a cell phone with you at all times.
- Memorize all important numbers.
- Establish a "code word" or "sign" so that family, friends, teachers, or coworkers know when to call for help.
- Think about what to say to the partner if he/she becomes violent.
- Remind the individual that he/she has the right to live without fear and violence.

If the person has left the relationship:

- Change the phone number.
- Screen calls.
- Save and document all contacts, messages, injuries, or other

incidents involving the batterer.

- Change locks, if the batterer has a key.
- Avoid staying alone.
- Plan how to get away if confronted by an abusive partner.
- If a meeting is necessary, have it in a public place.
- Vary the routine.
- Notify school and work contacts.
- Call a shelter.

If the individual is leaving the relationship or thinking of leaving, that person should take important papers and documents to facilitate application for benefits or take legal action. Important papers include Social Security cards and birth certificates for self and children, marriage license, leases or deeds, checkbook, charge cards, bank statements and charge account statements, insurance policies, proof of income (pay stubs or W-2s), and any documentation of past incidents of abuse (e.g., photos, police reports, medical records).

The National Coalition Against Domestic Violence provides information to health care providers, a network of shelters, and counseling programs, and operates a national hotline: 800-799-SAFE (7233); website: http://www.ncadv.org; address: One Broadway, Suite B210, Denver, CO 80203; phone: 303-839-1852; fax: 303-831-9251; telecommunication device (TTY): 303-839-1681; e-mail: mainoffice@ncadv.org.

Genogram

A **genogram**, or family diagram, represents the family on the basis of

identification data that depict each member of the family with connections between the generations. This useful technique gathers data on at least three generations, including the current one; their parents, grandparents, aunts, uncles; and their children. The genogram explores clues within family histories contributing to health problems. Figure 7-2 depicts accepted genogram symbols, with a sample genogram of the fictional Graham family portrayed in Figure 7-3 (Stanhope & Lancaster, 2015). The Graham family genogram shows a variety of family structures, including changes resulting from marriage, divorce, death, and childbearing. This information highlights family health patterns to use for anticipatory health guidance; for example, in the case of the Graham family, hypertension, type 2 diabetes, cancer, and hypercholesterolemia. Family histories provide the unique perspective of family risk of inherited diseases as well as the family environmental contribution (Pender et al., 2014). Although *My Family Health Portrait* (https://familyhistory.hhs.gov/FHH/html/index.html) takes a more traditional approach to family history, encouraging families to visit the website helps them explore their own family history. Resources for this continuously evolving topic of genomics can be found at the National Human Genome Research Institute (http://www.genome.gov/HealthProfessionals/), and on-line genetics education resources can be found at the National Institute of Health's National Genetics Research Institute at http://www.genome.gov/10000464. Box 7-6 explores how family assessment incorporates genomics.

Symbols to describe basic family membership and structure.

Family interaction patterns. The following symbols are optional. The clinician may prefer to note them on a separate sheet or the ecomap.

FIGURE 7-2 Genogram symbols. (Modified from McGoldrick, M., Gerson, R., & Petry, S. [2008]. *Genograms: Assessment and intervention* [3rd ed.]. New York: Norton.)

Box 7-6

Genomics and Family Assessment

Family assessment is the first line of assessment for genetic testing. Family assessment encompasses both genetic and environmental risks shared among family members. Family assessment provides the foundation for the complex process of genetic assessment, which includes nondirective genetic counseling to facilitate the balance of

risk versus benefit (Wilson & Nicholls, 2015).

Thanksgiving Day, a day in the United States when families customarily gather, has been designated by the US government's Family History Initiative as Family History Day. Family History Day sets aside Thanksgiving Day as a time when family members can discuss their health history (https://www.genome.gov/17516481/). Multiple tools have now been designed to facilitate gathering and sharing information in preparation for use in an electronic health record (EHR) environment. The design of these tools is intended to improve quality, while decreasing disease burden and cost.

Evidence supports multiple genomic interventions that are derived from accurate family assessment. A number of conditions have been identified as tier 1 disorders. Tier 1 designation indicates that genomic and family health history synthesized studies support implementation of the evidence into practice. Currently the following disorders that rely on accurate family assessment are classified as tier 1:

Breast/Ovarian Cancer

- Hereditary breast and ovarian cancer in women (see Box 6-6: Genomics)
- *BRCA1* and *BRCA2* genes related
- Deleterious mutation of the BRCA gene
- Chemoprevention of breast cancer

Colorectal Cancer

- Newly diagnosed colorectal syndrome (test for Lynch syndrome; see Box 6-6: Genomics)
- Known Lynch syndrome in family

- Metastatic colorectal cancer *(KRAS* gene, cetuximab, panitumumab)
- Invasive colorectal cancer (carcinoembryonic antigen–related cell adhesion molecule 5)

Cardiovascular Disease

- Familial hypercholesterolemia (DNA testing and low-density lipoprotein cholesterol concentration measurement)
- Cholesterol screening

Other

- Osteoporosis screening in Women—parental history of hip fracture
- Hereditary hemochromatosis–family health history, especially siblings
- Newborn screening of 31 core conditions

Other tier 1 genomic applications, in addition to family assessment, could be used to reduce morbidity among affected people and their families (Douglas & Dotson, 2015).

Adding family health history to meaningful use standards for EHRs may also decrease the gaps between the evidence and how it is implemented in practice. Promoting the importance of family assessment through education and policy may facilitate identification of at-risk families (Kolor & Khoury, 2015).

From Douglas, M. P., & Dotson, W. D. (2015). J., & Nicholls, S. G. (2015). The Human Genome Project, and recent advances in personalized genomics. *Risk Management and Healthcare Policy*, (*8*)2, 9–20.

Ecomap

The **ecomap**, which is similar to the genogram, uses pictorial techniques to document family organizational patterns with visual clarity. A genogram is constructed for a family or household. It begins with a circle in the center of the page. Outside the circle, smaller circles are drawn and labeled with the names of significant people, agencies, and institutions in the family's social environment. Lines are drawn from the family-household to each circle. Solid lines indicate strong relationships. Dotted lines reflect fragile or tenuous connections. Slashed lines signify stressful relationships. Arrows can be drawn parallel to the lines to indicate the direction for the energy flow or for resources (Stanhope & Lancaster, 2012). Figure 7-4 shows an ecomap for the fictional Graham family. Both the genogram and the ecomap provide useful information and can be incorporated into family systems assessment (O'Brien, 2014; Tramonti & Fanali, 2015). The ecomap helps to overcome the issues of the genogram encountered when one is assessing nontraditional families. The ecomap uses a functional rather than a structural approach to the assessment of family roles and function.

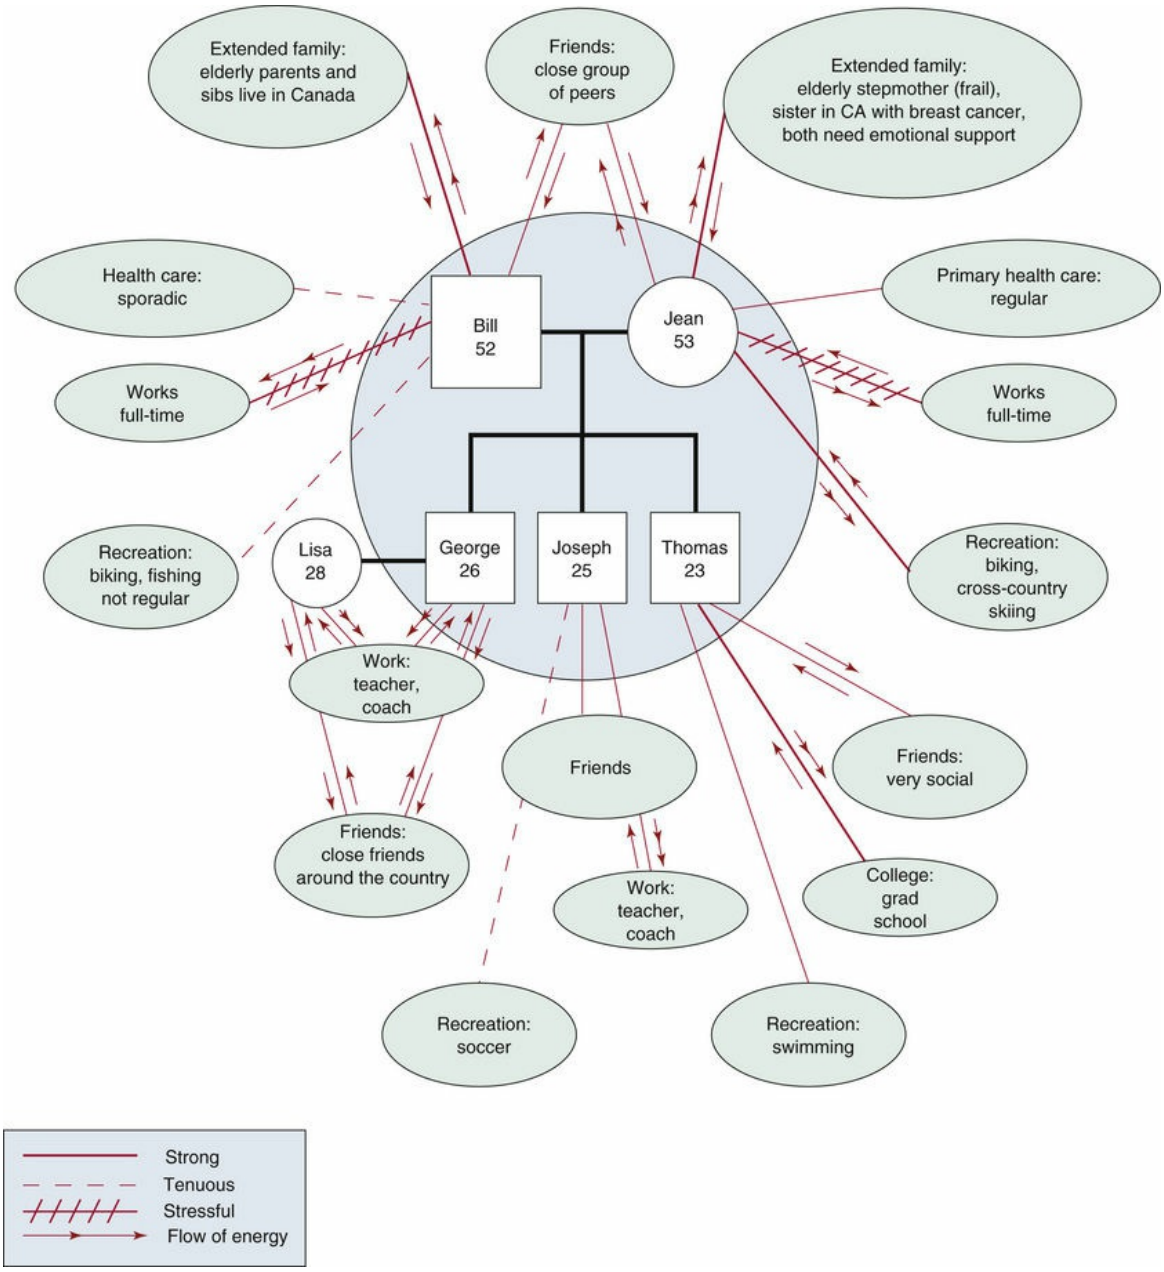

FIGURE 7-4 Ecomap of the Graham family. (From Stanhope, M., & Lancaster, J. [2012]. *Public health nursing: Population-centered health care in the community* [8th ed., p. 636]. St. Louis: Mosby.)

Health-promotion nursing relevance cannot be underestimated. Nurses who maintain competency position themselves to determine the most accurate risk profiles and family risk assessment.

Sexuality-Reproductive Pattern

Sexuality is the expression of sexual identity. The sexuality-reproductive pattern describes sexuality fulfillment (Gordon, 2016), including behavioral patterns of reproduction. This pattern also includes perceptions of satisfaction or disturbances in sexuality, sexual relationships, reproduction (including contraception), and developmental changes throughout the life span, such as menarche and menopause. The sexuality-reproductive pattern addresses transmission of information within the family about sexuality, as well as sexuality for the couple, including their sexual relationship, perception of problems, manner in which problems are handled, and actions taken to solve problems (Gordon, 2016). Information transmission during childhood is an important area to explore to better understand how issues related to sexuality and gender identity are addressed within the family (Gordon, 2016).

Topics to explore during the assessment may include the following areas:

- How do the adults in the family communicate their needs to each other?
- How do family members commit to, love, and care for each other, as well as fulfill their obligations and responsibilities toward one another?
- How do the adults in the family view marriage, parenthood, and their relationship as lovers?
- How does the family address family planning and birth control?
- How do family members participate in the choice of family planning and contraceptives used?

When needed, complete pregnancy histories include sexual practices and partners, the number and ages of children, the number and outcome of pregnancies (including live births, miscarriages, spontaneous/therapeutic abortions), and the birth control methods used. Nurses also observe the comfort levels the adults demonstrate when discussing their own sexuality, or if an adult seems uninformed when discussing sexual subjects with children. Because of the impact

that sexual relationships within the family have on children, exploring the variety of sexual practices within heterosexual, homosexual, and bisexual relationships in the family is an important part of health-promotion assessment (Hockenberry & Wilson, 2015). The onset of the use of electronic health records in many settings provides an opportunity to systematically assess and intervene to provide best practices and eliminate disparities in these populations (Donald & Ehrenfeld, 2015).

Coping–Stress Tolerance Pattern

The coping–stress tolerance pattern helps to depict the family's adaptation to both internal and external pressures (Gordon, 2016). On a daily basis, family members generate energy to face evolving needs. Society continually compels families to adapt to new situations. Survival and growth depend on coping mechanisms as families face external demands required to move from one developmental stage to the next. The family's ability to cope with everyday living demands determines family success. Family relationships support coping or generate more stress. Life events, such as divorce, moving, or developmental stages of the life cycle, and economic hardships, such as loss of a job, provoke stress and mobilize family coping strategies. Exploration of coping and stress tolerance includes the following assessment areas:

- How does the family cope with stressful life events?
- What experiences have family members had with chemical abuse?
- What strengths does the family have and use to counterbalance the stresses?
- What stressful family situations are experienced?
- How does the family view the association between stress and children's health and development?
- How does the family make appraisals of the situations, and are they realistic?
- Describe the family's resources. How do family members use

knowledge or links to family networks or community resources?

- What kinds of dysfunctional adaptive strategies are used, such as chemical abuse or violence?

Values-Beliefs Pattern

The values-beliefs pattern characterizes the family's perspective and attitudes about life meanings, values, beliefs, and spirituality and the way these issues affect behavior (Gordon, 2016). Assessment, diagnosis, and intervention are based on these attitudes. Assessment of this pattern enhances the interpretation of family behavior. Exploration of values and beliefs includes the following assessment areas:

- What are the values and beliefs held by the family?
- How flexible are rules?
- How do family members interact (calm, aggressive, competitive, or rigid)?
- How do family members view spirituality?
- Describe the cultural or ethnic group with which the family identifies. What family practices are consistent with the norms of that ethnic group? How are the practices inconsistent with these norms?
- What are the family's traditions and practices?
- How do the significant cultural beliefs affect health or illness?
- Describe the role that religion plays in the family on a regular basis and during times of stress. How does the family rely on religious practices?
- How does the family perceive its competency during crisis?
- What are the family goals, and do members perceive that they are attaining these goals?
- How are value conflicts demonstrated within the family?
- How do identified family values affect the health status of the family?

Spirituality, defined as life purpose and connection with others,

affects health. The metaphysical and transcendental phenomenon of spirituality, as well as the religious and nonreligious systems of belief within families, should be assessed (Denham et al., 2015). How well families communicate their unconditional love and forgiveness for injury or betrayal may contribute to physical symptoms within families. Clearly, spirituality and social skills promote health and prevent disease.

Data collected in the 11 functional patterns reveal ideas about family health-promotion and disease-prevention practices. Risks to healthy family functioning may be identified in each pattern. Risk factors may be found in more than one area. For example, passive smoke from one family member's cigarettes may be identified as an environmental risk factor in the home. However, the family's reaction to passive smoking determines the family members' perceived susceptibility, their perceived severity of the problem, and whether they will make a change in the environment to promote family health. The pattern indicates high risk if chronic asthma is described during the family history. In this situation, several other pattern areas support the finding. The nurse determines each risk behavior along with its effects on the others.

Environmental Factors

The environment also influences family health and well-being. The home, neighborhood, and community constitute the family environment. Assessment includes exploration of the following home environment areas (Figure 7-5):

FIGURE 7-5 Assessment of the home includes environmental assessment of the yard.

- What type of dwelling is it (condominium, single dwelling, low-income apartment, or temporary shelter)?
- How has the family acquired the home (purchase, rental)?
- What is the condition of the home (interior/exterior: glass, trash, broken stairs, peeling paint, inadequate insulation, inadequate lighting on stairs, or broken fixtures)?

- Are the number and type of rooms adequate for the size of the family?
- How satisfactory are the furnishings to meet the needs of the family (enough chairs and beds, and a kitchen table)?
- How comfortable is the temperature (warm in winter and cool in summer, insulated)?
- How adequate is lighting for reading, sewing, and other activities?
- How adequate is the water supply (sufficient/clean/fluoridated/polluted)?
- Does the family have access to a telephone, and are emergency numbers available?
- How safe are the kitchen sanitation and refrigeration capabilities?
- How adequate are the bathroom sanitation facilities, water supply, toilet, and towels and soap?
- Are the sleeping arrangements adequate for family members, considering age, sex, relationships, and spatial needs?
- How adequate is the plan for escape in an emergency (smoke detectors/escape route/plan inside the home)?
- What are the arrangements for and knowledge of first aid (directions posted for poisons, burns, lacerations, and other first-aid needs)?
- What signs of rats, mice, or cockroaches are present inside or outside the home?
- What are the family's impressions about the home? How do the family members describe the adequacy of their living space for privacy, their own interests, and status?
- How are chemicals stored in the home (out of reach of children)?
- How is safety ensured in the home? What safety issues are evident?

The areas to explore for neighborhood assessment are as follows:

- What is the condition of the dwellings and streets (maintenance/deterioration)?
- How and when is the garbage collected?
- What is the incidence of violent crime, burglaries, and automobile

accidents?

- What kinds of industry are nearby and do they produce air pollution or toxic waste?
- What are the social class and ethnic characteristics of the neighborhood?
- What are the occupations and interests of the families in the neighborhood?
- What is the population density?
- How available and accessible is public transportation? Why is public transportation not used if it is available?

Exploration during assessment of the community includes the following areas:

- What resources, such as schools, church, transportation, shopping, and recreational facilities, are available for family use?
- How accessible are the health facilities, such as physician's office, clinic, hospital, gym, swimming pool, natural food store, and weight-reduction clinic?

By driving or walking around the area, the nurse can obtain neighborhood and community data. Other sources of information include the family, health professionals, teachers, business people, and others who work in the area. Official resources, such as the reports from the US Census Bureau (http://www.census.gov/) or statistics from the city or state health departments and libraries, are also helpful in describing a neighborhood and community.

Analysis and Nursing Diagnosis

Analyzing Data

After completing the data collection, the nurse and the family analyze the data. Several approaches are used to analyze health data, including systems theory, developmental theory, and risk-estimate theory. A systems approach categorizes families as open or closed, with permeable or rigid boundaries determining both structural and functional components of family systems.

Developmental theory approaches families from the perspective of tasks and progression through cycles. Nurses analyze data to identify accomplishment of family life cycle stages and family tasks needed to function successfully. Family developmental needs are determined considering the wide variety of family structures and functions in society. Although most family models are based on nuclear family structures, additional family structures should be explored as indicated by current population trends (Brown et al., 2016; Coyne et al., 2016; Edwards, 2009). The stages of family development guide the baseline data analysis. Gaps, missing data, or conflicting information is identified and clarified.

Couple Family

The first stage of family development begins when adults define themselves as a family regardless of the legal status. When individuals move from their family of origin to a new couple relationship, adaptation to role expectations of a partner becomes a developmental task for each individual. Establishing a mutually satisfying adult relationship that converges with the kinship network is one family developmental task. Adjustment for couples includes learning how to weave together two personalities, two life histories, and two aspirations of growth. Decisions in this stage include whether adults are gainfully employed, how money is managed, where they live, how they socialize with friends and other family members, patterns of

sexual activities, and whether the couple has decided to have children. Determining how to divide household tasks of cooking, washing, cleaning, and shopping occurs either consciously or subconsciously.

Developmental tasks that integrate health practices and habits into the couple's lifestyle require consideration during analysis. Health behavior constitutes particular actions to promote health and prevent disease. Examples of health-promotion and disease-prevention activities may include maintaining well-balanced rest, exercise, diet, and contraception; attending smoking-cessation classes; wearing seat belts; and directing activities toward self-actualization. Each individual brings values and beliefs to the relationship. Practices from the family of origin and values from personal experiences combine to form the adult beliefs of the individual. Achieving mutually satisfying relationships also depends on couples' conflict management. Strategies that stem from congruent value systems facilitate couple's adjustment. When couples use divergent strategies, problem-solving tends to be less effective.

Childbearing Family

Decisions about adding children to the family commit couples to more complex long-term responsibility. Family development and primary health needs change to focus on additional members. To analyze the learning needs of couples with a pregnant member, nurses consider aspects of decisions and motivations involved with the pregnancy. With single-parent families (usually mothers) becoming increasingly common through divorce, death, adoption, or the choice to have a child out of wedlock, analysis of family function addresses these diverse family structures (Atkin et al., 2015; Coyne et al., 2016; Edwards, 2009).

Attitudes and practices in society regarding sexuality have influenced the incidence of sexually transmitted diseases, such as genital herpes, gonorrhea, and syphilis. Acquired immunodeficiency syndrome (AIDS), first described in 1981, poses a threat to the family and society, in addition to affected individuals. Human immunodeficiency virus (HIV) is transmitted through heterosexual,

homosexual, or oral sexual intercourse, as well as through direct contact with infected blood, shared needles during intravenous drug use, and perinatal transfer from infected mothers to their infants. Prevention of HIV transmission requires abstinence from and modification of relevant behaviors.

Risk factors associated with sexuality include lack of knowledge of safe sexual practices, the reproductive system, and personal hygiene; lack of prenatal care; pregnancy before age 16 years; pregnancy after age 35 years; a history of hypertension or infection during pregnancy; and unplanned or unwanted pregnancy.

Risk factors for premature pregnancies and unsatisfying marriage consist of ignorance about, or values regarding, family planning; adolescent age; and sexuality and role adjustment problems. In unplanned pregnancies, adolescent parents put themselves and their developing child at risk. Lack of knowledge of prenatal care, childbirth, and childrearing practices compounds the risks for both the mother and the child. Parents who are unable to perform parenting roles risk an unsatisfying relationship and inappropriate developmental growth for this beginning stage of the family life cycle. If couples decide to remain childless, learning needs include information about contraception.

The birth or adoption of a child begins a new family unit. Family members adjust to new roles as the unit expands in function and responsibility. As described more fully in the section Formulating Family Nursing Diagnoses, parents' history as a dyad and their experiences in other groups, particularly their families of origin, influence the development of the triad (Box 7-7: Diversity Awareness). Accommodating new members disrupts family equilibrium. As a group, families explore ways to meet each other's needs, to minimize differences, and work together. First-time parents often feel a lack of emotional support during the first several months of parenthood. Some, but not all, new parents have available family leave policies that may facilitate this transition. Without a family network or friends, the first days after the birth or adoption may be difficult. Parents may care for the child proficiently, but may need assistance to grow in the

parenting role. If parents are both employed outside the home, they may encounter difficulty with the routines of baby care and being confined to the house more for child care. Anxiety about the adequacy of income may cause parents to increase their work hours to increase their income. Exhaustion for both parents is common from working full-time while providing child care as the infant develops. Single parents, usually mothers, carry these same burdens alone. Emotional support may be limited, particularly if one has not found satisfaction in parenthood. The families of origin or other support systems, such as self-help groups, neighbors, or friends, assist family members as they struggle to adapt to a new member. King and colleagues (2015) reported their findings from a US longitudinal study (Adolescent and Adult Health). Their structural equation modeling indicated that perceived family belonging for adolescents of stepfather families (n = 2085) was strongly associated with the perceived quality of parent relationships particularly with both the stepfather and the birth mother. Nurses facilitate processes within families of origin, families of choice, or other support systems to promote health in the newly formed family unit.

Box 7-7

Diversity Awareness

Preconception Care

Preconception care is a significant health-promotion opportunity for the whole family. The importance of this care has been recognized by *Healthy People 2020,* the Institute of Medicine, and the Public Health Services Expert Panel on the Content of Prenatal Care.

One important area of preconception care is evaluating a couple's genetic history as documented on the standard family genogram. Further evaluation should be considered for couples who are related outside marriage or who have ethnic backgrounds such as Mediterranean, black, or Ashkenazi Jew, and for women older than 35 years or younger than 16 years who have preexisting medical

conditions. Couples who have family histories of any of the following health problems should be referred for further genetic testing and counseling: cystic fibrosis, hemophilia, phenylketonuria, Tay-Sachs disease, thalassemia, sickle cell disease or trait, birth defects, or mental retardation.

Modified from Johnson, K. A., Floyd, R. L., Humphrey, J. R., Biermann, J., Moos, M. K., Drummon, M., et al. (2014). Action Plan for the National Initiative on Preconception Health and Health Care (PCHHC). A report of the PCHHC Steering Committee. http://www.cdc.gov/preconception/documents/ActionPlanNationalInitiativePCHHC2012-2014.pdf.

Some parents thrive during the period when an infant needs almost constant care and nurturing. These parents find support in a network of family and friends. Couples who find satisfaction in parenthood seem to realize that parental influence begins at birth and is the single most important factor in the child's physical, emotional, and cognitive development. The parents' ability to assume responsibility depends on a complex array of factors: their own maturity; how they were nurtured as children; their conceptions about self, culture, social class, and religion; their relationship with each other; their values and philosophy of life; their perceptions of and experiences with children and other adults; and the life stresses they have experienced.

In analyzing the needs of childrearing families, nurses consider many factors, including providing for physical health, economic support, and nurturing actions that are vital to learning and social development of children. In analyzing couples' needs during this stage, nurses recognize the importance of interactions among the triad. Observing decision-making helps nurses determine family functioning, member roles, and effectiveness of family members. Risks associated with role relationships include working parents with insufficient resources for child care, abuse or neglect of children, multiple closely spaced children, low family self-esteem, children used as scapegoats for parental frustration, immature parents who are dependent and unable to handle responsibility, and strong beliefs about physical punishment or obedience.

Family With Toddlers/Preschool Children

Families may have more than one child, each growing and developing at an individual pace. Preschool children place great demands on families. Families adjust to each new member with space and equipment for expansion. The needs and interests of preschool children influence home environments. Nurses assess the quality of the home environment for whether children have healthy amounts of stimulation-promoting opportunities. Safety balanced with exploration by the child results in health-promoting home environments. Rather than removing children from the kitchen or garden, finding ways to include them in a cooking or planting activity provides learning experiences. Other environmental influences affecting the child's rate and style of development include religious practices, ethnic background, education, and discipline techniques.

Evidence increasingly demonstrates the link between environment and health. Home environments that contain contaminated air, water, or food increase health risks. For example, lead poisoning, a preventable disease that continues to affect thousands of children, often results from lead paint and other factors in the home, such as water. Although restrictions exist in the United States to limit lead-based paint to exteriors, many homes have lead in the interior. Generally, lead in water is attributed to poor infrastructure in the home plumbing or the city. As a result, poorer neighborhoods are at higher risk of lead poisoning from their water source. For example, families in Flint, Michigan, experienced increased lead in the water coming into their homes when the local government changed their water source. Hanna-Attisha and colleagues (2016) reported the incidence of elevated blood lead levels within the city (n = 1473; before change 736; after change 737) increased from 2.4% to 4.9% ($p < 0.05$) after a water source change without a comparable change in blood lead levels outside the city (n = 2202; before change 1210; after change 992). The incidence of elevated blood lead levels was highest in neighborhoods with poor families. Both homes and automobiles are also considered possible sources of exposure to the poisonous agent carbon monoxide. Nurses also review data for home safety, including

storage of dangerous materials, such as detergents, insecticides, and medications.

Health-promotion needs for young children include proper foods, adequate exercise and sleep, and dental hygiene. Parents teach children through modeling and use of positive reinforcement. Family developmental tasks include adjusting to fatigue resulting from parenting demands. Nurses explore alternatives to relieve parents. Parents need time for themselves, individually and as a couple (e.g., to exercise, socialize), while knowing their children are safe with a responsible person. Economic restraints may limit relaxation time away from the children. Sharing child care with friends and the family provides one source of support for new parents.

Family With School-Age Children

A family with children in school may have reached its maximal size in numbers and interrelationships. The parents' major problem during this stage is the dichotomy between pursuing self-interests and finding fulfillment in producing the next generation. Family developmental tasks revolve around goals of reorganization to prepare for the expanding world of school-age children. School achievement becomes a critical task for socialization. Viewing social and educational goals from the perspective of family culture and parents' defined goals becomes particularly important during this developmental stage. For example, many opportunities for health education exist in schools, including influencing healthy beliefs and behaviors. However, school health programs focus on problems such as tobacco and substance abuse with messages aimed at problems and crises rather than healthy behaviors. Families influence health at home and in school both by teaching children ways to assess and manage risky situations and by describing the benefits to expect when healthy behaviors are practiced.

As children's activities broaden away from the home, another important developmental task for both the parent and the child becomes “letting go.” Parents become involved in community groups such as the parent-teacher association, scout groups, sports teams, and

other volunteer organizations. Encouraging children to join in family discussions to learn about their heritage can foster understanding of self within the family network (Figure 7-6). Children exposed to unsafe home environments are at risk of behavior disturbances, school problems, and learning disabilities. Parents who cannot manage their children in growth-promoting ways soon experience energy depletion and may turn to dysfunctional relief from parenting (e.g., drug and alcohol abuse).

FIGURE 7-6 School-age girl learns about her family heritage and presents this information through a school project.

Family With Adolescents

Parents with adolescent children may experience a late pregnancy, resulting in care for an infant while other children in the family are in school. A new family member at this stage may be a source of joy or

frustration for the family. The overall goal with adolescent members is to loosen family ties to allow greater responsibility and freedom in preparation for releasing young adults. Although each member of the family strives to achieve individual developmental tasks in the midst of social pressures, the family as a whole has tasks to accomplish. Strengthening the marital relationship to build a foundation for future family stages is a critical task during this time.

Open communication is often difficult during this stage, partly because of the differing developmental tasks of adolescents and adults. Adolescents seek their own identity, and adults attempt to facilitate adolescent decision-making processes. Choices about values and lifestyles may differ. Adolescents may challenge family values and standards. Although parents maintain some authority, adolescents tackle their own desires and needs. Adolescents want to do what their friends do, have their own cars, and make their own money to spend in ways that they see fit. Parents who give adolescent members opportunities to experience social, emotional, and ethical situations with others are providing learning opportunities to enhance their sense of autonomy and responsibility. As adolescents become mature and emancipated, families face balancing freedom with responsibility. Health problems in this age group include violent deaths, including suicide, injuries, and alcohol and drug abuse. Contributing risk factors involve lack of problem-solving skills, family values of aggressiveness and competition, socioeconomic factors, peer relationships, rigid and inflexible family values, daredevil risk-taking attitudes, and conflicts between parents and children. Environmental risk–related violent deaths and injuries are influenced by the highway system, automobile manufacturers, and the legislation of standards of safety. Families rely on public health officials and nurses' efforts as advocates to reduce environmental risks.

Families support adolescents in this stage of development by including them in decision-making and ensuring that they experience the positive and negative consequences of their choices. Family values of winning at all costs, aggressiveness, and competition may need to be explored during this period. Adolescents may discard these values

if they are no longer applicable. Considerable change in adolescent values produces conflict and poses a threat to family cohesiveness. Families may place pressure on adolescents to conform to family values. In matters of life and death—for example, in regard to driving rules—parents must stay firm.

Families with adolescents experience identity crises for the adolescent, the adults, and the family as a whole. Adolescents move from childhood to adulthood while adults progress beyond parenthood. Adolescents struggle to find independent identities that remain connected to their family. Adults, in midlife, must resolve their own adolescent fantasies to move toward an identity for their remaining life.

Family With Young Adults

Families with young adults act as a launching center when children begin to leave home. As children leave home, parents relinquish their parenting roles of many years to return to the marital dyad. The couple builds a new life together while maintaining relationships with aging parents, children, grandchildren, and in-laws. Couples focus on redefining relationships during this stage. As children develop, they no longer need a primary caregiver, often their mother, in the same way as during childhood. When mothers/caregivers devote years to raising children, their role and purpose within the family changes as children develop. Transition from a life with children as the priority to new or renewed interests (e.g., career, community service) may require assistance and support from the entire family. Careers at this stage may become more stable. Developmental tasks at this stage for the family's adults require focus on future prospects. In addition to individual changes occurring at this stage, families with young adults may experience other pressures. Aging parents and adult children may require financial or emotional support. Financial and emotional responsibilities to other family members hinder the couple's ability to focus on relationships during this developmental phase. Health-promoting activities to be focused on during this stage include coping with pressures of social roles and occupational responsibilities,

maintaining health tasks to promote healthy aging, and reassessing life goals.

Family With Middle-Aged Adults

Families consisting of only two members are able to enhance self-concept and support their relationship during middle age. Usually children have left home and adults experience a sense of freedom and well-being. Some relationships, by this stage, have reached a level of security, stability, and meeting each other's needs. Parenting pressures diminish, allowing parents to enjoy the accomplishments of their children and grandchildren. Couples have acquired a network of friends. Long-time acquaintances seek participation from the couple in neighborhood rituals and events. Economic security and personal self-esteem may be at a peak.

In contrast, some relationships falter at this time. Departed children create a quiet house with less activity, known as the “empty nest.” When individuals are unprepared for this stage, they might seek opportunities to enhance self-concept from outside of the family. With parenting roles now complete, adults may develop feelings of inadequacy or begin new relationships, start new families, or resort to substance abuse. In addition, this life phase may include becoming grandparents, parenting grandchildren, coping with the needs of middle-aged children, and caring for older adults (children, siblings, or parents).

Health tasks in this developmental stage require new awareness of susceptibility or vulnerability to health problems. Couples adjust their lifestyle and habits to cope with health risks. Losses promote health problems, and at this stage couples begin to cope with deaths among family and friends, along with declining income. If either member has developed physical or mental illness, the other adjusts to the resultant physical and mental impairments, redefining self-concept.

Middle-aged families face a host of risk factors leading to three prevalent causes of death: heart disease, cancer, and cerebrovascular accident (stroke). Family lifestyle may decrease risks by placing a high value on being physically active, refraining from smoking,

maintaining adequate and sound nutritional habits, and consuming moderate amounts of alcohol. Lifestyle habits that are transmitted through role modeling have a greater influence on the younger members of the family than any verbal edict. Middle-aged members positively influence their health if they are able to choose environments low in water and air pollution and free from crippling stress factors such as excessive noise, traffic, and overcrowding. Family members can also apply pressure on key members of the community to decrease risks in the environment.

Family With Older Adults

Retirement affects many aspects of life for couples and each individual in the family and their relationships with others. Besides decreased work hours, retirement also means reduction in income and fixed incomes for most people. Adjusting living standards to retirement income and being able to supplement this income with wage-earning activity is one task of the family with older adults. Other tasks during this stage include ensuring a safe and comfortable home environment, preparing for end of life, and adjusting to the loss of a spouse and finding meaning in the grief process (MacKinnon et al., 2016). In their qualitative pilot study, MacKinnon and colleagues (2016) reported that participants (n = 12) used group intervention (meaning-based group counseling) to establish effective coping strategies, adapt to their loss, and reframe life goals.

Health promotion aims to maintain functional ability, limit the effects of disabling conditions, and maintain quality of life. Older adults may fear becoming helpless, feeling useless, and being incapable of caring for themselves. When analyzing risk factors in the aging family, nurses look for the couple's ability to function well enough to carry out normal roles and responsibilities. As with all people, older adults hope for a state of well-being that will allow them to function at their highest capacity physically, psychologically, socially, and spiritually (Figure 7-7). Many older adults remain in their own homes, and most of these individuals are vigorous and completely independent. Assuming that most older adults prefer to

remain in their own homes, assessment of the family for this age group should consider predictors of independence or those factors that indicate a need for institutionalized care such as assisted living, adult day care, or nursing homes. In their report of a longitudinal 22-year study of 1032 Finnish adults aged from 73.1 to 92.3 years (average age 83.5 years), Salminen and colleagues (2016) reported that falling several times a year, absence of nearby assistance, diminished cognitive function, and both high and low body mass index significantly increased the likelihood of institutionalization. These findings highlight the importance of assessing fall risk, social support networks, cognitive function, and body weight in families with older adults.

FIGURE 7-7 As with all people, older adults hope for a state of well-being that allows them to function at their highest capacity physically. Medicare now has a yearly wellness visit

for those older than 65 years.

Ego integrity (the union of all previous phases of the life cycle) is the challenge in this stage and demands successful aging through continued activity. Having gone through the various stages of family development, the couple accepts what they have done as their own. At this time, they may need family or professional support to pursue other interests or maintain former activities to feel needed and useful.

The nurse and the family jointly analyze the information, comparing the family's data with documented norms of health promotion and disease prevention in older adults. Norms or expected values can be derived from the family's baseline information of 11 functional pattern areas, knowledge of growth and development for all age groups and the family as a whole, risk-factor estimates, and population norms. Population norms specify normal ranges for these groups. For example, age is associated with various risk factors; some disorders are so common that they are referred to as diseases of the older person. In certain diseases, such as lung cancer, there is a long period of exposure. Risk increases with cumulative exposure; therefore the incidence and prevalence of diseases increase with age.

Sexuality.

Because of the popular perception that older adults are asexual, their sexual concerns may be disregarded (Salladay, 2016). The strength of sexual desire of the older women may be more influenced by age, education, and attitude than by biomedical factors.

General population norms for values, beliefs, self-perception, or role relationships may be less available than physical population norms. Cultural, ethnic, and religious factors contribute to values and beliefs about health. Family baseline information provides important comparative criteria for analysis. Family records provide useful information when available. The first contact assessment provides baseline information for subsequent comparison and evaluation of progress. Whether the family perceives situations to be problematic should also be considered in the analysis phase. Nurse and family perceptions about problems may differ.

Formulating Family Nursing Diagnoses

Writing a **family nursing diagnosis** helps families promote health throughout the life cycle and prevents disease through decreasing risk-taking behaviors. Nurses derive diagnoses from assessed validated data. As a concise summary statement of a problem or potential problem, diagnoses provide direction for outcomes and interventions by identifying negative health states and factors to change to alleviate or prevent the problem (see Chapter 6). Describing health and validating potential or actual health problems with families facilitates cooperation. Assessment and negotiation continue until agreement occurs and a plan for resolution develops.

Cultural competence and respect for familial beliefs forms a foundation for the nursing process of assessing, determining nursing diagnoses, planning, intervening, and evaluating (see Chapter 2 for more detail). With changing trends in families and shifts in heritage within society, cultural competence and cultural attunement become priorities for family assessment and nurses. Pandit and colleagues (2014) define "socio-cultural attunement (SCA) as the ongoing process of experiencing clients' emotions around the intersection of socio-cultural contexts (i.e., gender, race, ethnicity, religion, sexual orientation, etc.)." Their definition of sociocultural attunement (SCA) was derived from a study that developed a working model of SCA in which 13 therapists and five couples participated in a total of 25 therapy sessions. Four cycles of qualitative analysis resulted in a working model for the SCA process. The process of SCA these researchers designed includes three recursive phases: the initial guiding lens, sociocultural interpretation, and client and therapist resonance (Pandit et al., 2014).

Cultural values, such as those connected to nutrition, influence most health-promotion practices. As globalization occurs, diversity will also expand, and competent care for indigenous populations and migrating populations will be needed (Andrews & Boyle, 2015). Cultural competence increases the efficacy of health promotion for all families, particularly families from within vulnerable populations (Andrews & Boyle, 2015).

Planning With the Family

Intervention planning stems from complete assessment, analysis, and nursing diagnosis. The plan's purpose aims for behavioral change in families to promote health or prevent dysfunction. As in the assessment phase, family members play an active role in the planning process. Family responsibility for personal health status enhances the success of behavioral change outcomes. The planning process involves several steps, with the nurse and family identifying the following:

- Order of priority for problems or potential problems
- Items that can be handled by the nurse and the family and items that must be referred to others
- Actions and expected outcomes

The nursing plan provides direction for implementation and the framework for evaluation (see the care plan at the end of this chapter).

As mentioned, a family's health status can be diagnosed as functional, potentially dysfunctional, or dysfunctional. Functional family health status warrants verification by the nurse with a plan for periodic reevaluation that is formulated jointly. Plans to continue healthy living behaviors are reinforced. The nurse provides specific information requested by the family, such as immunization schedules, growth and development milestones, and recommended dietary allowances. In working with healthy families, the nurse controls the assessment and analysis phases of the nursing process. If the health status is judged functional, then planning health-education materials, scheduling periodic examinations, and providing accessibility of the nurse remain professional responsibilities. Implementation and evaluation of health-promotion activities become family responsibilities.

In health-promotion and disease-prevention settings, life-threatening situations rarely occur; however, when such situations do occur, they become the highest priority for intervention. For other identified potential or actual problems, the nurse relies on the family

to decide which problem or potential problem to approach. After the ordering of priorities has been established, the family and nurse determine who will work on the problem. Problems or potential problems to be resolved by the nurse are identified separately from those requiring referral or family intervention. Problems for the family to handle or those the family is already addressing are considered strengths and are acknowledged and supported by the nurse. For example, when there is consistency among values and actions, physical fitness, weight management, and ability to cope with stress, the family is already taking informed and responsible action in these areas. The extent to which family members can provide their own health promotion and disease prevention will depend on their knowledge, skills, motivation, and orientation toward health.

Problems that need medical, legal, or social attention are referred to appropriate agencies. The nurse should have a directory of resources in the community when referrals are needed. Nursing intervention requires clearly stated actions that are purposeful, moral, capable of being accomplished, and adapted to the particular life situation, beliefs, and expectations of the family.

Goals

Goals are statements describing desired outcomes. Family outcome statements include expected family behaviors, circumstances for exhibited behaviors, and criteria for determining performance. Health-promotion goals reflect a desire to function at a higher level of health and to grow beyond maintaining health or preventing disease.

Implementation With the Family

The implementation phase is dynamic. As the nurse and family work together, new information is used to adapt and change the plan as necessary. **Family nursing interventions** aim to assist families in performing functions that members cannot perform for themselves. In health promotion and disease prevention, nurses assist families to improve their capacity to act on their own behalf. Ten studies were identified in a systematic review of the literature about family interventions (Deek et al., 2016). This review linked reduced readmission rates, emergency department visits, and anxiety levels and family-centered interventions. Evidence to support the use of family-centered interventions, including active learning strategies, transitional care, and appropriate follow-up in families with chronic conditions, was presented.

Families may know that they take risks by smoking, drinking, and engaging in a stressful lifestyle. As the nurse explains the rationale behind the proposed changes, families may choose to deny how they jeopardize their future health and continue their risk-taking behaviors. Factors that the nurse has not considered may cause the family's resistance. For example, families may have more pressing basic needs such as food, clothing, and housing. The Patient Protection and Affordable Care Act (2010) addressed some of these health care issues of the family by permitting parents to retain children on their health insurance plans until the age of 26 years, regardless of their marital status, living situations, or employment (unless in some cases where health insurance is an employee benefit). New insurance plans must cover preventive benefits such as well-child visits and immunizations without additional cost to the insured. Although the Patient Protection and Affordable Care Act (PL 111-148) became law on March 23, 2010, and was amended by the Health Care and Education Reconciliation Act of 2010 (PL 111-152), the statute was brought before the US Supreme Court beginning March 26, 2012, as unconstitutional, citing four major arguments (requiring the

individual mandate, applying the Anti-Injunction Act, lacking a severability clause, and expanding Medicaid). The Supreme Court ruled in favor of the statute in June 2012.

Health promotion and disease prevention may not have been part of the family's life experiences, giving the nurse the educational task to try to change attitudes and values by expanding the options for families to consider health promotion. Four types of nursing interventions appear in health-promotion and disease-prevention planning: increasing knowledge and skills; increasing strengths; decreasing exposure; and decreasing susceptibility. Increasing knowledge and skills to improve family capacity for health-promotion and disease-prevention behavior may be the primary strategy. Use of this strategy helps families make informed choices about healthful lifestyle behaviors and to eliminate harmful environmental influences that affect health. Improved knowledge aims to create awareness as the nurse and family work together to uncover actual or potential problems. Nurses recognize particular families at risk and move toward motivating and supporting behavioral change in these families. Box 7-8: Innovative Practice presents an example of one program that provides education and support to people with cancer and their families.

Box 7-8

Innovative Practice

The Wellness Community and Gilda's Club

The Wellness Community, which was founded in the 1982 by Dr. Harold Benjamin in California, has many local chapters throughout the United States. Comedian Gilda Radner attended the Wellness Community during her battle with ovarian cancer and shared her experiences in her book *It's Always Something*. After her death, Joel Siegel and Mandy Patinkin began Gilda's Club and opened the first club house in New York in 1991 with the support of her spouse Gene Wilder. These two organizations shared 45 years of offering free

educational and support programs for people with cancer and their families on both coasts. Emphasis is placed on the family to acknowledge that no person with cancer makes the journey alone. Weekly support groups help family members support one another, explore new ways of coping with the stresses of cancer, and learn ways to become the most effective partners possible with their health care teams. These two organizations have now partnered to continue their vision with the Cancer Support Community to "ensure that all people impacted by cancer are empowered by knowledge and strengthened by action, and sustained by community."

These communities now offer a wide variety of workshops and programs (Gentle Strength and Stretch, Meditation and Guided Imagery, Nutrition Matters, Nutrition and the Immune System, Nutrition at Midlife: Preventing Heart Disease and Osteoporosis, tai chi, yoga, mindfulness, and feng shui). Social events are organized (comfort food potluck dinner, couples networking groups, singles networking group, family and friends networking group). Although chapters generally do not charge for their services, donations are appreciated and necessary to help serve the thousands of people with cancer and their families.

Family strengths or forces that contribute to family unity and solidarity foster the development of inherent family potential (Carrascosa, 2015). These factors include:

- Physical, emotional, and spiritual factors
- Healthy childrearing practices and discipline
- Meaningful and clear communication
- Support, security, and encouragement
- Growth-producing relationships and experiences
- Responsible community relationships
- Growth with and through children
- Self-help and acceptance of help
- Flexibility in family functions and roles
- Mutual respect for individuality
- Crisis as a means for growth
- Family unity and loyalty and intrafamily cooperation
- Adaptability of family strengths

In recent years, a shift of family health care from an illness or problem and deficiency focus to a strength-based focus has occurred (Aston et al., 2015). Multiple models in nursing view families as systems and base their assessment and nursing process on strengths rather than deficits. These models of nursing provide the framework to assess and plan care using family strengths and resources (Carrascosa, 2015). Family members develop and maintain health-promoting behaviors by using commitment, appreciation, affection, positive communication, time together, a sense of spiritual well-being, and ability to cope with stress and crisis. Multiple assessment tools are available for nurses to use to generate discussion among family members about their strengths. Aston and colleagues (2015) describe the importance of corresponding nursing interventions to support and

further develop the family dynamics of socialization, support, and nurturance.

Families with significant strengths may need to learn new, unfamiliar skills for mastering a specific technique, such as meditation, and to apply new tools for decision-making. These families rarely require ongoing supervision or support of sustained interventions aimed at changing their coping patterns, communication, or role behavior. They may be highly capable of seeking and using information. Assisting functional families may simply involve providing information in terms that can be understood and offering opportunities to ask questions and clarify information. Unit 3 contains individual chapters devoted to many of the strategies commonly used in health-promotion intervention, such as health teaching and counseling.

Decreasing exposure to risk factors may include enhancing parents' ability to assess and adjust their behavior to their child's temperament. Parents with limited literacy may need assistance to learn to respond constructively to their child's communication attempts. Health promotion includes teaching parents to avoid exposure to risks—for example, to use adequate restraints in automobiles, to protect their toddler from wandering into dangerous streets, and to supervise children to avoid falls and hazardous materials.

Although no substitute can be found for continuous supervision of a child, homes can be made safer if common hazards are moved out of children's reach. This effort includes storing all cleaning solutions and medications beyond children's reach; erecting barriers in front of exposed heaters, high windows, and stairways; keeping pots and pans turned inward on the stove; fencing in a yard or a swimming pool; and teaching children to avoid dangerous areas. Becoming aware of peeling paint and toxic chemicals that parents might carry home from the job on their clothing can also protect the child.

Decreasing susceptibility means educating families about prevention principles. Families who realize how diseases are spread are better able to avoid transmission from person to person; through air, water, and food; and by insects and the rodents on which insects

live. Health promotion includes emphasizing the role of personal hygiene and cleanliness to avoid infection. Families who know signs and symptoms that require medical attention and how to treat minor illnesses are better able to maintain healthy environments.

Pender and colleagues (2014) cite research that demonstrates how perceived susceptibility predicts preventive behavior. Perceived susceptibility is the family's estimated subjective probability that a specific health problem will be encountered. Family members' perceptions of health risks and their susceptibility to them will determine how they change their behavior. If the overweight family believes obesity is a threat to the health of the family, the family members are more likely to react positively to the changes suggested by the nurse than is a family who perceives no health threat. Nurses who introduce threat as a motivator to action are morally obligated to reduce the threat by meaningful and purposeful interventions. Table 7-2 lists various nursing roles used in the implementation stage.

Evaluation With the Family

The purpose of evaluation is to determine how the family has responded to the planned interventions and whether these interventions were successful. Goals and objectives that are stated in specific behavioral terms will make evaluation much easier than when they are given in general terms. The criteria used to evaluate interventions, such as weight change, increased lung capacity from an exercise program, and lower pulse rate as a result of relaxation exercises, are simple to measure. Other results of health promotion and disease prevention are not as easy to measure but must be considered in the evaluation step of the nursing process. When considering such factors as values, beliefs, self-perceptions, or role relationships, the nurse may base the evaluation on whether the family indicates that the interventions were successful. Additionally, the family's baseline data are used as comparative criteria in evaluation. The nurse reassesses the situation and compares the new information with that on the original assessment to determine whether change has occurred.

The following five measures of family functioning can be used to determine the effectiveness of interventions: changes in interaction patterns; effective communication; ability to express emotions; responsiveness to needs of members as individuals; and problem-solving ability. Using these measures, the nurse returns to the original assessment of the family's functioning and compares current observations with previous data. These characteristics of family functioning continue to provide a useful framework even today, when family structures are becoming more diverse and the nuclear family is becoming less prevalent (Brown et al., 2016; Coyne et al., 2016; Edwards, 2009).

When, during the planning phase of the nursing process, the nurse has identified the criteria (norms and standards) for the desired outcomes, these outcomes are the basis of evaluation. Data from the family that describe the behavior of family members relative to the

desired outcomes determine whether the nursing care was successful. With the criteria stated, the goals and objectives outline how the family can demonstrate a successful outcome and the behavior change expected to result from nursing intervention. The more objective and measurable the desired outcome is, the more reliable the results of evaluation will be.

After the goals and objectives have been reached, the problem no longer exists. If evaluation shows the nursing actions did not achieve the goals or objectives, the nurse must review the nursing process to determine whether there were gaps in the assessment data, errors in analysis or nursing diagnosis, or alternative interventions that might have been considered. The nurse also needs to review the process with the family to determine whether the family members have contributed to outcome failure. Finally, the agency employing the nurse may be another factor; if intervention is costly or a shortage of staff exists, then health promotion and disease prevention may have low priority.

Case Study

Family Member With Alzheimer Disease: Mark and Jacqueline

Mark and Jacqueline have been married for 30 years. They have grown children who live in another state. Jacqueline's mother has moved in with the couple because she has Alzheimer disease. Jacqueline is an only child and always promised her mother that she would care for her in her old age. Her mother is unaware of her surroundings and often calls out for her daughter Jackie when Jacqueline is in the room. Jacqueline reassures her mother that she is there to help, but to no avail. Jacqueline is unable to visit her children on holidays because she must attend to her mother's daily needs. She is reluctant to visit friends or even go out to a movie because of her mother's care needs or because she is too tired. Even though she has eliminated most leisure activities with Mark, Jacqueline goes to bed at

night with many of her caregiving tasks unfinished. She tries to visit with her mother during the day, but her mother rejects any contact with her daughter. Planning for the upcoming holidays seems impossible to Mark, because of his wife's inability to focus on anything except her mother's care. Jacqueline has difficulty sleeping at night and is unable to discuss plans even a few days in advance. She is unable to visit friends and is reluctant to have friends visit because of the unpredictable behavior of her mother and her need to attend to the daily care.

Reflective Questions

- How do you think this situation reflects Jacqueline's sense of role performance?
- How do you think that Jacqueline may be contributing to her own health?

Care Plan

Family Member With Alzheimer Disease: Mark and Jacqueline

***NURSING DIAGNOSIS: Risk of ineffective role performance related to caring for a family member with Alzheimer disease**

Defining Characteristics

- Feeling exhausted
- Inability to complete tasks
- Feeling loss of usual or expected relationship with care receiver
- Increased stress or nervousness about the future

- Preoccupation with care routine
- Withdrawal from social contacts or change in leisure activities

Related Factors

- Illness severity of care receiver
- Increasing needs of care receiver
- Addiction or codependency of caregiver or care receiver
- Conflicting role demands
- Caregiver health impairment
- Unpredictable illness course or instability in the care receiver's health
- Psychological or cognitive problems in the care receiver
- Caregiver not developmentally ready for caregiving role
- Developmental delay or retardation of the care receiver or caregiver
- Marginal family adaptation or dysfunction before the caregiving situation began
- Marginal coping patterns of caregiver
- Providing direct, ongoing in-home care
- History of poor relationship between caregiver and care receiver
- Care receiver who exhibits deviant, bizarre behavior
- Incontinence in the care receiver

Expected Outcomes

- Caregiver distinguishes obligations that must be fulfilled from those that can be controlled or limited.
- In conjunction with the nurse, the caregiver develops a plan of care for the individual.
- Caregiver receives and accepts appropriate levels of support from family members, friends, and others.
- Caregiver describes help available from informal and formal support systems in the community and takes steps to obtain help.

Interventions

- Assess the level of the caregiver's stress.
- Assist the caregiver in developing a realistic plan of care, considering the care receiver's abilities and limitations; the plan will require modification as the person decompensates.
- Instruct the caregiver to encourage the person to participate, to the greatest extent possible, in social and self-care activities such as bathing, dressing, dining out with friends, and playing cards.
- Facilitate a family meeting to help the primary caregiver seek assistance from other family members.
- Support the caregiver and family members as they adjust to the degenerative nature of the disease; be aware that over time the stress associated with caring for the person increases.
- Identify community resources that may offer the caregiver relief from constant supervision of the individual (home health aides, respite care, and adult day care).

- Help the caregiver contact informal sources of support, such as church groups, extended family, and community volunteers.
- Encourage the caregiver to attend an Alzheimer disease support group.
- Refer the caregiver to the Alzheimer's Association.

*NANDA Nursing Diagnoses—Herdman, T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Learning about health promotion and disease prevention begins at birth, with the family providing the stimulus for incorporating health in the value system of its members. From a systems perspective, the family has both structure and function; relevant functions include values and practices related to health. The effective execution of health-related functions involves the family's progression through its developmental tasks and its ability to generate low risk-producing behaviors associated with disease prevention.

Developmental and risk-estimate theories can be applied effectively to the nursing process with the family. The nurse uses functional patterns (an inherent part of both theories) to collect data for assessment. After organizing information on family life cycle stages for analysis with the family, the nurse writes the nursing diagnosis and plans, implements, and evaluates the interventions used to promote health and prevent disease in the family.

Health Promotion and the Community

Anne Rath Rentfro

OBJECTIVES

After completing this chapter, the reader will be able to:

- Describe the 11 functional health patterns and explain how they are used for data collection to assess communities.
- Evaluate community characteristics that indicate risk.
- Identify developmental aggregates of potential or actual dysfunctional health patterns.
- Explain methods of community data collection and sources of information.
- Describe a method of planned change for the community.
- Discuss the planning, implementation, and evaluation of nursing interventions in health promotion with communities.
- Develop a health-promotion plan based on community assessment (including resources), nursing diagnoses, and other contributing factors.

Think About It

Teenagers: Drinking and Driving

In a small rural community, seven teenagers have died in alcohol-related car accidents within the past 3 months. Alcohol and drug education is taught during the first year at the local high school, but driver's education classes are not offered because the school cannot afford the program. Parents within

this community are extremely concerned.

- What other information must be acquired before a diagnosis is made?
- What health-promotion ideas could be recommended based on the information provided?

In the last few decades, several social trends in the United States have increased public interest in health promotion and disease prevention. The *Healthy People 2020* initiative shifts the focus of health care from reactive to proactive with its emphasis on disease prevention and health promotion (US Department of Health and Human Services, 2015). By stating national health objectives as population-specific risks to good health, this venture guides community strategies to promote health, thereby reducing disease risk factors. Box 8-1: *Healthy People 2020* highlights the emphasis this initiative takes in an environmental and community context.

Box 8-1

Healthy People 2020

Select Examples of National Health-Promotion and Disease-Prevention Goals and Objectives for Communities

The *Healthy People 2020* framework has expanded its focus to accentuate health-enhancing social and physical environments. Because the *Healthy People 2020* framework addresses health and health behaviors at multiple levels, almost all *Healthy People 2020* goals and objectives could be listed as examples of national health-promotion and disease-prevention objectives for communities. The following list consists of selected exemplars aimed specifically for aggregates and for health promotion rather than those that are

individual level objectives with a tertiary care focus. When multiple objectives for one topic are pertinent to community assessment, the more general goal rather than specific objectives is listed.

AH-Goal	Improve the healthy development, health, safety, and well-being of adolescents and young adults.
AOCBC-11	Reduce hip fractures among older adults.
BC-13	(Developmental) Decrease the prevalence of adults having high-impact chronic pain.
BDBS-Goal	Prevent illness and disability related to blood disorders and the use of blood products.
C-15-18	Increase the proportion of individuals who receive cancer screening and counseling.
CKD-1	Reduce the proportion of the US population with chronic kidney disease.
DIA-2	Reduce the proportion of preventable hospitalizations in adults aged 65 years or older with diagnosed Alzheimer disease and other dementias.
D-16	Increase prevention behaviors in persons at high risk of diabetes with prediabetes.
DH-Goal	Maximize health, prevent chronic disease, improve social and environmental living conditions, and promote full community participation, choice, health equity, and quality of life among individuals with disabilities of all ages.
EMC-4	Increase the proportion of elementary, middle, and senior high schools that require school health education.
ECBP-Goal	Increase the quality, availability, and effectiveness of educational and community-based programs designed to prevent disease and injury, improve health, and enhance quality of life.
EH-Goal	Humans interact with the environment constantly. These interactions affect quality of life, years of healthy life lived, and health disparities. The World Health Organization defines environment, as it relates to health, as "all the physical, chemical, and biological factors external to a person, and all the related behaviors." Environmental health consists in preventing or controlling disease, injury, and disability related to the interactions between people and their environment.
FP-Goal	Improve pregnancy planning and spacing, and prevent unintended pregnancy.
GH-2	Reduce the tuberculosis case rate for foreign-born persons living in the United States.
HC/HIT-13	Increase social marketing in health promotion and disease prevention.
HRQOL/WB-1	Increase the proportion of adults who self-report good or better physical and mental health.
ENT-VSL-Goal	Reduce the prevalence and severity of disorders of hearing and balance; smell and taste; and voice, speech, and language.
HDS-Goal	Improve cardiovascular health and quality of life through prevention, detection, and treatment of risk factors for heart attack and stroke; early identification and treatment of heart attacks and strokes; and prevention of repeat cardiovascular events.
HIV-Goal	Prevent HIV infection and its related illness and death.
IID-1	Increase immunization rates and reduce preventable infectious diseases.
IVP-Goal	Prevent unintentional injuries and violence, and reduce their consequences.
LGBT-1	Increase the number of population-based data systems used to monitor *Healthy People 2020* objectives that include in their core a standardized set of questions that identify lesbian, gay, bisexual, and transgender populations.
MICH-Goal	Improve the health and well-being of women, infants, children, and families.
MPS-2.1	(Developmental) Reduce the proportion of patients suffering from untreated pain due to a lack of access to pain treatment.
MHMD-2, 12	Reduce suicide attempts by adolescents and increase the proportion of homeless adults with mental health problems who receive mental health services.
NWS-Goal	Promote health and reduce chronic disease risk through the consumption of healthful diets and achievement and maintenance of healthy body weights.
OSH-1-2	Reduce nonfatal injuries and deaths and from work-related injuries.
OA-1-3 & 12	Increase the proportion of older adults who use the Welcome to Medicare benefit, have

	received current clinical preventive services, and report confidence in managing chronic conditions, and make information publicly available for older adults on the characteristics of victims, perpetrators, and cases of elder abuse, neglect, and exploitation.
OH-8, 9 & 13	Increase the proportion of low-income children and adolescents who received any preventive dental service during the past year and increase the proportion of school-based health centers with an oral health component and increase the proportion of the US population served by community water systems with optimally fluoridated water.
PA-2, 3 & 15	Increase the proportion of adults and adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity and increase legislative policies for the built environment that enhance access to and availability of physical activity opportunities.
PHI-2	(Developmental) Increase the proportion of tribal, state, and local public health personnel who receive continuing education consistent with the core competencies for public health professionals.
RD-7-8	Increase the proportion of persons with current asthma who receive appropriate asthma care according to National Asthma Education and Prevention Program guidelines and increase the number comprehensive asthma surveillance systems for tracking asthma cases, illness, and disability.
STD Goal	Promote healthy sexual behaviors, strengthen community capacity, and increase access to quality services to prevent sexually transmitted diseases and their complications.
SH Goal	Increase public knowledge of how adequate sleep and treatment of sleep disorders improve health, productivity, wellness, quality of life, and safety on roads and in the workplace.
SA-Goal	Reduce substance abuse to protect the health, safety, and quality of life for all, especially children.
TU-Goal	Reduce illness, disability, and death related to tobacco use and secondhand smoke exposure.
U-20	Increase the number of states and the District of Columbia, territories, and tribes with sustainable and comprehensive evidence-based tobacco control programs.
V-Goal	Improve the visual health of the nation through prevention, early detection, timely treatment, and rehabilitation.

From US Department of Health and Human Services. (2015). *2020 topics and objectives.* http://www.healthypeople.gov/2020/topics-objectives.

Another social trend creating interest for health promotion is the changing population of the United States (see Chapter 2). As baby boomers entered older age beginning in 2011, the older population continues to expand and will grow more in the next 2 decades (Figure 8-1). The proportion of those older than 85 years has also increased by almost 5% (8.8% in 1980; 13.6% in 2010) as the US older population continues to age (West et al., 2014). These changes in the rates of the oldest-old contribute to a growing number of older people with disability in our communities (He & Larsen, 2014). Community assessment for health promotion will need to consider disability more thoroughly, because disability is currently viewed from a social model perspective (resulting from social and physical barriers). Older people also tend to have more chronic diseases and consume larger portions

of health care resources than people in other age groups. This aging population will require more home services than previous generations because of increased life span and the concurrences of health problems (including altered levels of functioning).

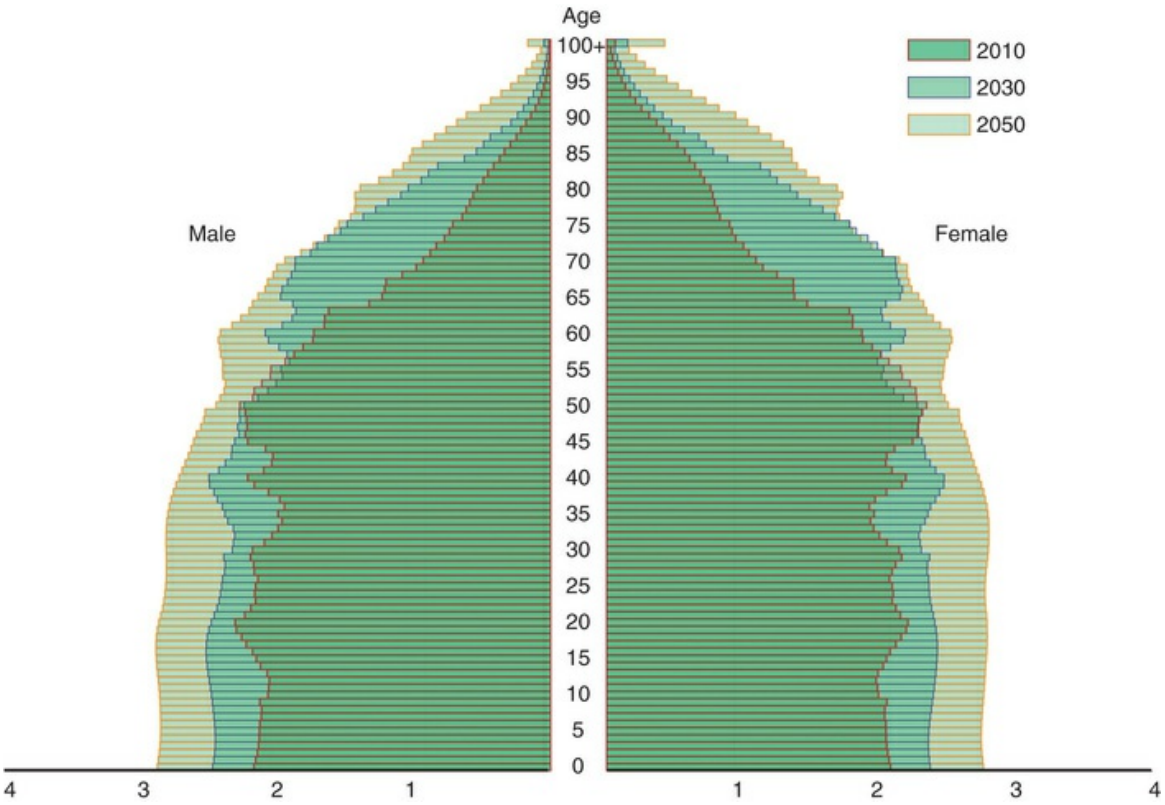

FIGURE 8-1 Age and gender structure of the population for the United States: 2010, 2030, 2050. (From Ortman, J. M., & Guarneri, C. E. [2009]. *United States population projections: 2000 to 2050.* http://www.census.gov/population/projections/files/analytical-document09.pdf.)

The term **community** is used in various contexts with various meanings, depending on the frame of reference. Nursing generally adopts a broad sense of community that includes the concepts of groups of people that share social relationships, generally live within the same geographical location, and share common interests (Stanhope & Lancaster, 2015). A broad definition of community encompasses a wide variety of settings, such as school, workplace, and the international community.

Nurses in the nation's schools serve youth and provide access to community resources. Linking school nurses with communities can increase access to resources to improve health-promoting behaviors. *Healthy People 2020* addresses this issue: "ECBP-5: Increase the proportion of the Nation's elementary, middle, and senior high schools that have a full-time registered school nurse-to-student ratio of at least 1 : 750" (US Department of Health and Human Services, 2015). In 2006 the Health Indicators Warehouse (http://www.healthindicators.gov/) reported that 40.6% (confidence interval 35.3–45.9%) of US schools had the specified full-time registered nurse-to-student ratio (1 : 750). The 2012 evaluation of this indicator is not yet available.

People are integral to any concept of community; human beings give each community shape, character, and form. The diversity within a community and the diversity among various communities contribute to the health of that community. Individual health is reflected in each community through each person's contribution to its statistical rates and cultural and psychological makeup. Conversely, the context of the community is reflected in the individual through similar modes of expression (Pender et al., 2014).

This chapter focuses on the application of the nursing process to the community with independent, interdependent, and dependent nursing activities. Globalization has affected communities. Swift methods of travel and Internet communication impact community health (Petersen et al., 2016; Young et al., 2016). Communities globally are exposed to emerging infectious diseases such as Zika virus disease, Ebola fever, severe acute respiratory syndrome (SARS), human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), and pandemics of tuberculosis and influenza (Petersen et al., 2016). For example, in 2016 the World Health Organization declared Zika virus disease a global emergency because of its associated serious newborn neurological disorders (microcephaly) and Guillain-Barré syndrome, and more than 50 countries reporting cases (http://www.who.int/emergencies/zika-virus/situation-report/28-april-2016/en/). Infected female mosquitos

transmit most Zika virus infections. Although sexual intercourse, blood transfusions, and perinatal transmission have been proposed as alternative means of contracting the virus, among mothers who delivered infants (n = 35) with microcephaly, 74% remembered rashes in the first or second trimester (21 in the first trimester). Most infected individuals (80%) experience few symptoms. The symptoms, such as fever, malaise, rash, conjunctivitis, headache, and muscle and joint pain, occur about 1 week after the insect bite, then last for about 1 week after onset (Petersen et al., 2016).

Disparities in health across the world are associated with poverty, industrialization, violence, social disruption, education, food access, and maternal health. Even in developed countries with health resources, disparity occurs. Health may be different in urban versus rural geographical areas. Rural communities are doubly disadvantaged, with lower levels of health-promotion behaviors and limited resources from local, state, and federal public health agencies (Harris et al., 2016). Compared with urban Americans, rural people have increased levels of all the following: death from chronic obstructive pulmonary disease, suicide, and obesity (Harris et al., 2016). Furthermore, rural individuals (23%) are more likely to lack health insurance than their suburban counterparts (19%) (Harris et al., 2016; Meit et al., 2014).

Methods of data collection and sources of information about communities differ from individual sources. **Systems theory, developmental theory,** and **risk-factor theory** guide the nursing process. Developmental theory refers to a variety of explanations of phases of human development—physical, psychosocial, cognitive, and spiritual dimensions—based on descriptive research studies. Similarly, risk-factor theory identifies human characteristics and behaviors that increase the likelihood of the manifestation of health problems. Diverse communities require comprehensive assessment techniques that gather information about the unique characteristics of the population (e.g., cultural health practices or herbal remedies).

Gordon's (2016) functional health patterns provide the assessment framework for this chapter. Although other community assessment

strategies exist, Gordon's (2016) patterns are useful to align community assessment findings with those of families and individuals to plan health promotion. An example of a data collection guide pattern is presented to facilitate the comprehension, synthesis, and application of **observation data, interview data, focus groups,** and **measurement data.** An example of data analysis, nursing diagnosis, planning, implementation, and evaluation follows, along with a description (Table 8-1).

TABLE 8-1

Implementation of Community Health Plans With Objectives and Rationale

Nursing Diagnosis: Potential for increasing the incidence of fatal motor vehicle accidents in high school population related to alcohol use and driving. **Goal:** North High School population will have reduced incidence (at least 20%) of fatal motor vehicle accidents related to alcohol use and abuse by December.		
Objective	**Plans**	**Rationale**
1. Community will have access to information about incidence of fatal motor vehicle accidents and drunken driving arrests of its high school population for the past 5 yr by March	Interview local police about the incidence of fatal automobile accidents and substance abuse in the community. Interview parents of deceased high school students, students, teachers, physicians, clergy, and emergency department personnel about the incidence of the problem and suggested measures for decreasing the incidence; suggest that interviews be broadcast over the high school radio station. Have several people write to the community newspaper, commenting on the broadcast and the problem.	*Unfreezing:* For change to occur, the community has to become dissatisfied with the status quo and sense a need for change. *Empiric-rational strategy:* People are rational; discussion of facts can result in support for change. Important elements for preventing the problem include educating the public and having key community leaders discuss their views; concern lends credibility and is necessary for action. People tend to listen to those with informal power. Keeping the issue before the community can raise consciousness.
2. Community will take action to inform the population at risk about responsible drinking and driving by June	Suggest to the school principal and the school board the creation of a task force of community residents to plan a health program on individual responsibility and alcohol use in high school. Conduct focus group discussions with the task force and develop collaborative group goals and strategies. The task force should include teachers,	*Changing:* Moving to a new level; community involvement will influence acceptability of changes. Community residents like to be involved in decision-making. It is important to establish trust and collaboration

	students, parents, clergy, police, nurses, and physicians. The task force will examine ways to determine and teach content, integrate it into the curriculum, and recommend that community members, such as a nurse, be involved in teaching content.	among community groups; this opens communication channels between adolescents and the health community. Community involvement facilitates acceptance of change.
3. Community will implement an educational program for its high school population related to use of alcohol and individual responsibility	Implement educational plans.	*Refreezing:* Moving to level of change brought about by community forces. Educational strategies built around the concept of individual responsibility are essential elements in promoting health of young adults.

The Nursing Process and the Community

Community nursing stems from a theoretical base that recognizes the impact of systems on health. General systems theory (described in Chapter 7) provides a foundation for most methods community nurses use to assess, plan, and evaluate (Stanhope & Lancaster, 2015). Because nursing theories often address self-care and individual-environment interaction, nurses are well prepared to function in this setting. Public health theory uses a population focus with risk identification to assess communities. Assessing aggregates is therefore an important part of community nursing assessment (Thomas et al., 2016).

The approach to community nursing assessment addresses each community as unique and provides the rationale for the assessment. The community nurse may use a comprehensive needs-assessment approach that includes all aspects of the community and is the traditional rigorous approach (Thomas et al., 2016). The approach selected by the nurse determines the data to be collected. In strength-based approaches and Gordon's functional pattern approach, positive factors play a consistent role in the information gathering.

Gordon's (2016) health-related patterns provide a useful guide to collect observation, interview, and measurement data. Health-related patterns depend on community settings, assessment focus, and the preference of each community. Assessing all pattern areas provides a basic data set to analyze and use for comparison during evaluation (see Chapter 6).

Risk factors and development also influence health patterns. For example, health concerns may occur in one pattern area, such as the increased age-related factor of teenage pregnancy (sexuality-reproductive pattern). Data from other areas may reveal that parental opposition (values-beliefs pattern) tends to restrict sex education and limit sex education in schools (coping–stress tolerance pattern).

Attempting to restrict sex education or "ignoring" it in school and primary care may place the community at risk of unwanted pregnancy in its young people of childbearing age. Factors from several pattern areas may form clusters of risk for certain groups (see Chapter 6).

The Nurse's Role

Community health nursing combines nursing practice and public health concepts to promote the health of populations without limitation to any particular individual or group of individuals (Stanhope & Lancaster, 2015). Nursing concerns become the community's responses to existing and potential health-related problems, including such health-supporting responses as monitoring and teaching population groups. Nurses supply educational information to at-risk communities to develop health-oriented skills, attitudes, and related behavioral changes.

Community nurses also develop essential relationships aimed at accomplishing the community's health-related missions. Complex and dynamic communities, with their increasing public involvement in health and health policy, highlight the importance of human interactions inherent in nurses' responses to potential health problems, needs, and expectations. For example, active participation in environmental issues, such as decreasing control of toxic substances, provides an avenue for nurses to promote healthy environments by influencing policy.

In June 2015, the US Congress passed a bill to reform the Toxic Substances Control Act of 1976. The US Senate passed legislation in December 2015 that will move the bill to conference committee to be reconciled with the bill passed by Congress. Nurse opinion at this stage in the development of the new law may influence legislators to construct a law that considers issues related to public health, such as preventing toxic toys from being imported and maintaining the states' influence over chemical regulation. According to Katie Huffling (2015), “Nurses have been instrumental in states like Maryland, Washington, New York, and Connecticut in pushing for laws to protect children and families from toxic chemicals. By taking away the rights of states to regulate these chemicals, dangerous chemicals are protected regulation for years before the federal government acts.”

Concern about harmful effects of environmental contaminants

includes decreased fertility in women, demasculinization of men exposed to plastics, and premature maturation of the reproductive tract with a trend toward earlier sexual maturation. Community nursing practice, therefore, requires a broad knowledge base derived from the natural, behavioral, and humanistic sciences with application of intellectual, interpersonal, and technical skills using the nursing process.

Influencing Health Policy

The primary responsibility of the nurse is to the individual, family, group, or community served. A major portion of the nurse's role is to be an **advocate** not only for the individual but also for justice in health care delivery. Nurses need to be aware of issues that have an effect on the health of the American people and know how to influence necessary change.

Health and the environment are integrally connected; therefore nurses who engage in all planning aspects facilitate the health potential of those communities they serve. Involvement that includes attention to policy decisions and political action affects broader aspects of environmental, biophysical, and socioeconomic conditions of homes, schools, workplaces, communities, and health care delivery. For example, nurses could take active roles in how plastics impact population health (http://envirn.org/pg/groups/3755/environmental-health-scope-and-standards-of-practice), and in safeguarding natural resources. One organization, the Alliance of Nurses for Healthy Environments (ANHE), has created a website called the Knowledge Network (http://envirn.org/) to facilitate nurses' participation and competence in environmental health issues. In 2010 ANHE and the American Nurses Association (ANA) joined forces to develop the ANA's *Scope and Standards of Practice for Nurses* (Leffers et al., 2015). By virtue of their numbers, nurses, who constitute the largest group of health care providers in the United States, have tremendous potential to influence decision-making.

Participation in **policy decision-making** requires that nurses take a proactive stance to determine needs before a problem arises. Policy

development and change occur on many levels, from within the nurse's agency or work group to the community, state, and national levels. At the institutional level, clinical decisions influence policy, as do management issues. The nurse examines the rationales underlying existing or planned policy and determines their current relevance. Nurses, by virtue of their education and experience, develop communication skills and apply change theory to influence policy.

Health-related decision-making often results from legislation at the local, state, or national level. Laws—rules enforced by a ruling authority by which society is governed—and regulations—agency or department rules developed to implement laws—define the services offered. Politics influence change and provide an arena for nursing to participle in shaping the future of health care. Political involvement may include voting, communicating with local representatives, supporting candidates, contributing time or financial support, and running for city, county, state, or national office. Voting, after nurses have become well informed on current issues and candidates, and serving on local and state committees are important ways for nurses to be actively involved.

In addition, knowing local representatives, informing them about health care issues, and advising them as to their constituents' needs are other ways nurses become involved. Legislators are influenced by the information that they receive and by the sources of that information. Nurses have a wealth of knowledge about health care. The process of seeking to influence legislators' views and votes is called **lobbying.** When an individual is employed to lobby, he or she is known as a **lobbyist** and is required to register as the representative of a special interest group. The ANA, located in Washington, DC, employs nurse lobbyists, as do many states. Individual nurses, however, can support colleagues who represent nursing's interests and who run for political office. The ANA Nurses Strategic Action Team (N-STAT) network is an organized grassroots effort by nurses to help elect endorsed candidates and to inform legislators about policy issues of concern to nurses. When nurses join N-STAT, they receive alerts and updates detailing specific legislative issues. Financial

contributions to Nurses for Political Action Coalition, the ANA's political arm, increase the power base of nurses. Membership of professional and community groups provides nurses with the collective voice to influence legislators.

Communicating with a legislator is essential and can be done by phone, writing a letter, personal visits, or e-mail correspondence. Legislators have staffs of experts in various areas, and each legislator is assigned to committees. To understand the legislative process, the nurse follows the progress of a bill. Thousands of bills are introduced at both the state level and the federal level and must be passed within 2 years or they will die by default. Once a bill has been introduced, it is referred to committee, and the committee chairperson determines which bills will be considered. Hearings are then held on the considered bills. When hearings have finished in committee, a bill is "reported out" at the federal level to the floor of the Senate or House of Representatives for a vote. Both the Senate and the House of Representatives must pass identical versions of the bill and, once passed by both chambers, it is forwarded to the President for signing. If signed, it is enacted into law (Bhushan, 2015). It is important for nurses to lobby, to inform legislators of new issues, and to give expert testimony on introduced bills. Nurses who are politically aware extend the collective nursing voice to its full potential.

Unfortunately, nursing's collective voice is rarely heard. Only about 20% of the entire nursing workforce are members of a collective professional organization (Woodward et al., 2015). Other health care professionals, such as members of the American Medical Association, have more united professional organizations with large memberships, providing a united voice and political clout that influences health care policy and law. Nurses have multiple professional organizations. With high membership dues, nurses likely join only a few groups and may gravitate toward their specialty organization. Without a single national organization with the majority of nurses as members, nursing's voice is diluted. When organizations promote an issue, the collective voice of the group rather than the voice of the individual sends a more powerful message to influence policymakers. Without a

collective voice, nursing's influence on shaping health care policy is weakened.

To strengthen nursing's collective voice, the ANA has undergone significant reorganization with emphasis on increasing membership, by collaborating with its state constituent organizations, specialty organizations, and nonnursing health organizations. Engaging students in these strategies early in legislative processes will help to provide more well-informed practicing nurses. Well-informed, empowered professional nurses play significant roles in supporting legislative initiatives that promote and protect the health of the public. Other ways for nurses to be involved in policy change are to support candidates and run for office. Volunteering during campaigns to help a specific candidate or to encourage voter registration and voting are ways that nurses can influence policy. Many nurses now represent their local constituencies and have increasing visibility at the state and national levels. For example, five nurses currently serve in the United States 114th Congress (http://www.nursingworld.org/MainMenuCategories/Policy-Advocacy/Federal/Nurses-in-Congress).

Community nurses' roles include the interaction of independent, interdependent, and dependent functions. Independent functions include assessing, analyzing, diagnosing, planning, implementing, and evaluating communities for health promotion and health education. Interdependent functions include collaboration with community members and interdisciplinary teamwork functions that are crucial to effective community health. Dependent functions include implementing the therapeutic plans of team members.

Community health promotion includes all the following (US Department of Health and Human Services, 2015):

- Community participation, with representatives from multiple community sectors, including government, education, business, faith organizations, health care, media, voluntary agencies, and the public
- Assessment guided by a community-planning model to determine health problems, resources, perceptions, and priorities for action
- Targeted and measurable objectives to address health outcomes, risk

factors, public awareness, services, and protection

- Comprehensive, multifaceted, culturally relevant interventions that have multiple targets for change
- Monitoring and evaluation of the objectives and strategies used

Methods of Data Collection

Nurses obtain community assessment data through observation, interviews (including focus groups), and measurement. These three methods are used most frequently in various combinations to ensure the validity of the information. Obtaining data through observation—often referred to as the **windshield survey** approach to assessment—includes the use of the senses (sight, touch, hearing, smell, and taste) to determine community appearances. These appearances include the types and condition of residential dwellings and their people and also physical and biological characteristics, such as animal and plant life, temperature, transportation, sounds, and odors. Some communities have a characteristic "flavor." A community's physical characteristics influence health. What type of space is available? Children need space to run and play; young and middle-aged adults require space for recreation and exercise. What spatial barriers exist? Where is this space located in relation to traffic and schools? What does the air feel and smell like? What does the water taste like?

Community nurses obtain abundant subjective data by simply walking or riding around a community. Data obtained by observation provide important clues about the community, its actual or potential health problems, and its strengths. Technological advances such as the use of geographical information systems (GIS) enhance nurses' ability to assess communities. For example, Keddem and colleagues (2015) identified community vacant properties, illegal dumping, parks, tree canopy, aggravated assaults, and theft to assess neighborhood irritants, neighborhood safety, walkability, pollen, and environmental allergens. The influence and intensity of these community features on asthma control was analyzed by use of GIS.

Analysis of observation data generates hypotheses to explore further with use of interview, focus group, and measurement data.

Interview data, the most common source of information from people, include verbal statements from community residents, key community officials, health care personnel, and various community

agency staff. **Key informants** provide useful ways to learn how members perceive their community. Key community leaders often provide important information about community health concerns, necessary health resources, and community strengths, along with particular health beliefs and community health goals. Community residents provide useful information about their perceptions of health, health concerns, and needs, as well as their perceptions of the availability, accessibility, and acceptability of health services. Health agency personnel provide data about health resources, the population served, availability, and perceptions of concerns and needs. Developing a basic set of questions in advance enhances the relevance of interview data.

Community partners can be approached in groups to participate in assessment, planning, intervention, and evaluation (Andrews et al., 2012b; Frerichs et al., 2016). Community nurses who have expertise in building partnerships engage the community partnership model to conduct assessment, planning, the choosing of effective strategies, and evaluation (Stanhope & Lancaster, 2015). Andrews' research team uses this strategy for multiple community issues and health-promotion projects. The toolkit used for assessing partnership readiness is available on-line at http://academicdepartments.musc.edu/sctr/programs/community_enga Strategies initiated by engaged community members empower community partners and enhance the ability to transfer evidence-based strategies into their unique communities.

Measurement data use instruments to quantify data during information collection. Measurement data include population statistics, pollution indices, morbidity and mortality rates, census statistics, and epidemiological data. These data can be accessed by the Internet or locally in community libraries; health departments; environmental protection agencies; schools; police and fire departments; local health system agencies; and town, city, or state planning offices. Publicly supported agencies share their information, and community nurses readily use such data.

Sources of Community Information

Census information available from http://www.census.gov, and also found in libraries and public agencies, is the most complete source for population information. Because the US Census is completed once every 10 years at the beginning of a decade, data for most communities become less accurate as the decade progresses. Community agencies and local planning commissions, project statistics, and developmental trends are how nurses understand population patterns and dynamics. Many communities and states also have databases available for public use.

Environmental measurement data can be obtained from the local branch of the US Environmental Protection Agency. Generally, local health departments monitor water, food, and sanitation systems. Nurses may be called on to facilitate safeguarding of natural resources protecting communities from industrial toxins. In areas that use well water, testing should be performed regularly. Community health nurses can participate in interventions to promote testing to assure the safety of water used in home. For example, Nova Scotia and areas across the northern United States risk exposure to arsenic that occurs naturally in the groundwater (Chappells et al., 2015). At-risk private well users should be testing their well water regularly. Community nurses in this setting could intervene using an integrated knowledge-to-action method. This method would include strategies including community outreach, home visits, and environmental home assessment planning. These strategies use community partnerships and home visits for informing the public and testing water in the private wells. Possible long-term public health initiatives for involvement of community health nurses include trainings that include awareness, testing, and treatment; low-cost or no-cost convenient testing stations; and mandatory regulated enforced testing at the point of property transfer or when new wells are constructed (Chappells et al., 2015).

Health departments along with school nurses and administrators

provide school health information. Town, city, or county administrators provide information about land use, boundaries, housing conditions, utilities, and community services. Community newspapers supply information about community dynamics, health-related concerns, cultural activities, and community decision-making. The documentation techniques for community observation, interview, and measurement data are similar to those used for individuals and families. A triple-column format that separates the data obtained with each method facilitates recording.

Community From a Systems Perspective

Systems theory provides an overall framework to connect and integrate community data. Systems consist of interrelated, interacting parts or components within boundaries that filter both the type and the rate of input and output (Frerichs et al., 2016). Similarly to how families form systems (see Chapter 7), communities viewed as systems have both structure and function. Assessment of communities includes exploration of aspects of the population within specific geographical areas.

Structure

The **structure of a community** system or subsystem consists of a formal or informal arrangement of parts, including both animate and inanimate properties. Nursing, which operates within the context of the health system, can be considered within the context of community systems. Figure 8-2 shows the arrangement of a community system. The macrosystem includes societal ideologies, social norms, and culture, and shapes the larger part of the system that encompasses numerous subsystems, the exosystem, microsystem, and the individual (Joly, 2016). Communities' structural parts form the subsystems, each of which is in itself a system. Health agencies, schools, fire departments, and governmental bodies are examples of structural parts. Joly (2016) places Bronfenbrenner's bioecological theory into a contemporary context. The subsystems, such as individuals, family, school, and community, lie within overarching macrosystems. These systems and subsystems interact and change over time within a social context. For example, development during adolescence and young adulthood influences the disparity found in social determinants that subsequently impact health (Joly, 2016). The arrangement and organization of a community, such as age distribution and types of health-promotion/protection programs,

change over time. The parts fluctuate depending on environmental processes occurring locally and within the larger environment.

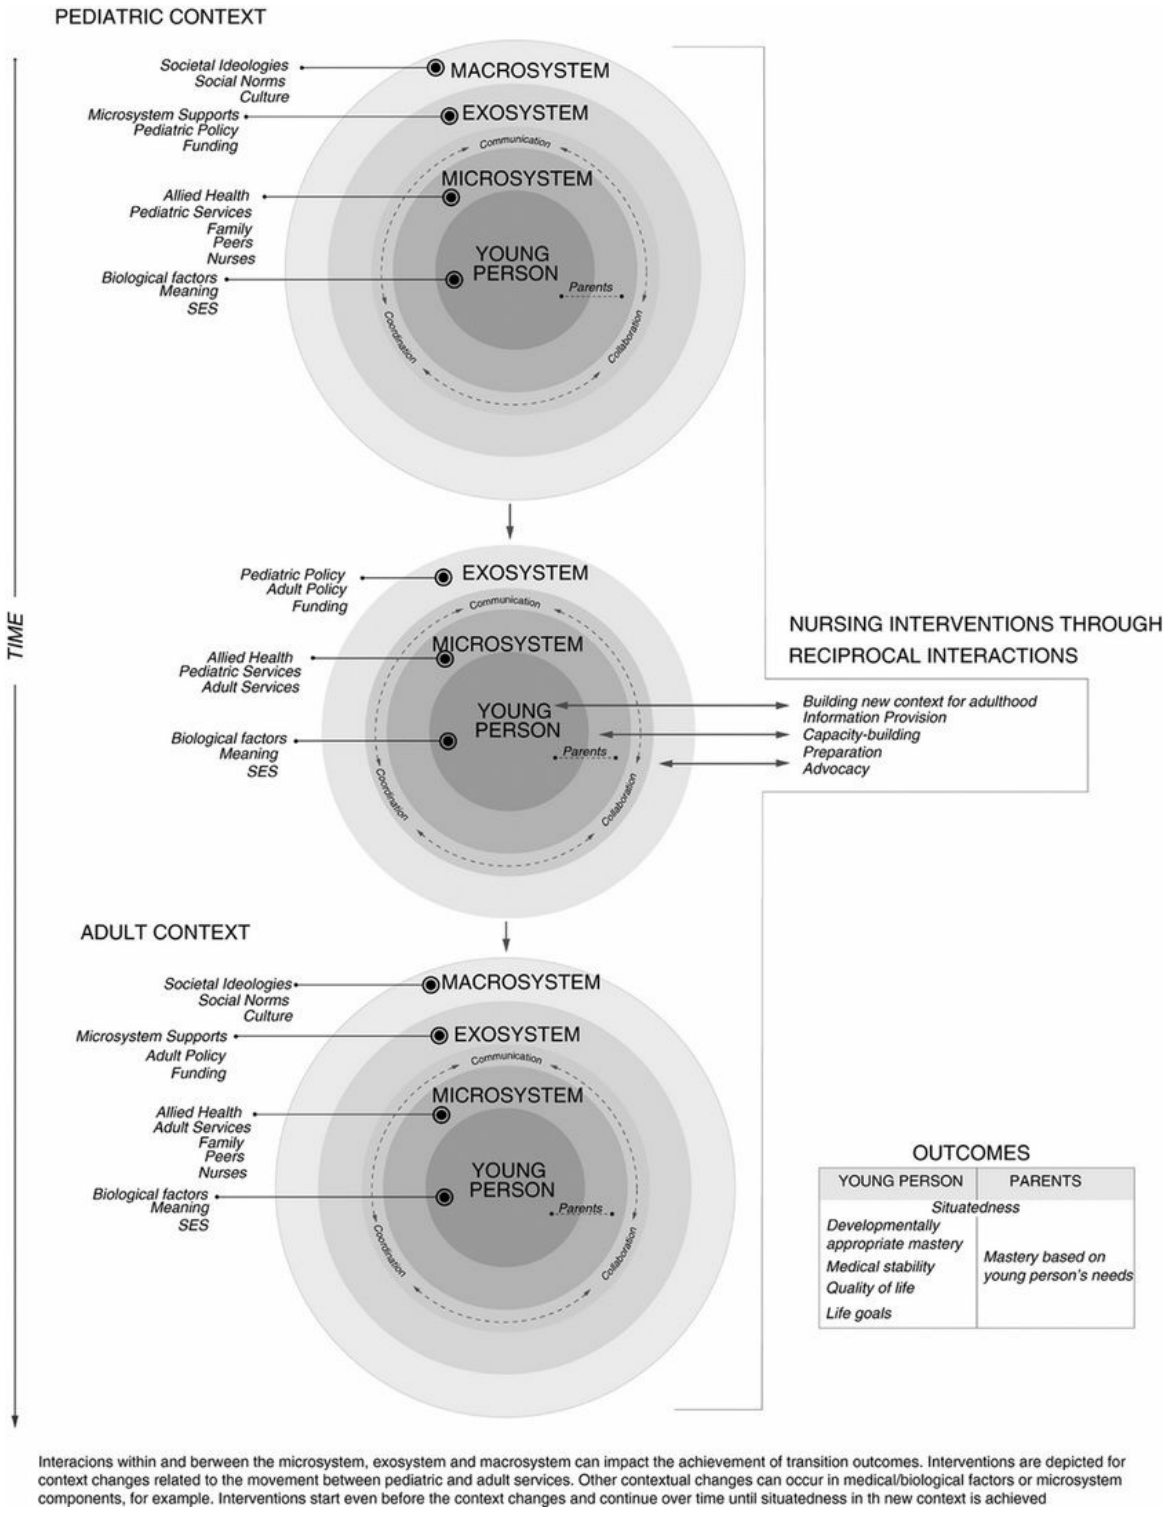

FIGURE 8-2 Community systems and subsystems model. *SES,* Socioeconomic status. (From Joly E. [2016]. Integrating transition theory and bioecological theory: A theoretical perspective for nurses supporting the transition to adulthood for young people with medical complexity. *Journal of*

Advanced Nursing, 72[6], 1251–1262.)

Community leadership provides direction for both health-promotion and health-protection activities; therefore community assessment includes exploration of various community systems as they relate to health. The practice of viewing community structure as a population (collection of people) and considering the arrangement of the community's health care parts (existing health services) plays an important role in the assessment process.

The study of populations is referred to as **demography.** A population is a group defined as an aggregate of people who share similar personal or environmental characteristics. Demography provides information about population characteristics—such as size and racial composition, along with the distribution of age, sex, marital status, nationality, language, religious affiliations, education, and occupation. Demographic data provide the basis for analysis and a means to identify groups who may have high risk of health concerns. Such information also provides direction for health strategies. For example, examination of the age distribution over several years reveals important population shifts with associated needs for additional health-promotion activities. The increasing numbers of individuals older than 65 years require changes in community health priorities that reflect this group's needs. Comparing population characteristics statistically enables nurses to make inferences about the community. Comparisons are made among three systems: the town, which is a part of the county; the county, which is a part of the larger system; and the state. Comparisons between affluent and poor communities, rural and urban communities, and diverse and homogeneous communities may provide important information for planning.

Function

The **function of a community** refers to the process of dynamic change with adaptation in the system's parts and the ways that community systems and subsystems interact. Decision-making and allocation of

health-promotion and health-protection resources are important considerations for community assessment. As health educators, nurses interact with communities to promote health. Community health promotion involves a complex array of responsibilities. Nurses act as advocates using proactive planning and collaboration with other disciplines and agencies. As a community liaison, the nurse establishes priorities for programming, matches resources with needs determined by a community needs assessment, empowers community members, and facilitates social, environmental, and political change. These multifaceted functions require expertise in communication and interpersonal relations that involve a deliberate approach. Using such an intentional process, while maintaining the community's vision, nurses can produce effective change.

Interaction

Through dynamic interaction with the environment, systems exchange matter, energy, and information (in such communication forms as verbal and behavioral) to make decisions. Interaction also contributes to community systems' survival ability, as well as to protect and promote the health of community members. Through environmental interactions, community systems use adaptation mechanisms. Nurses determine how communities apply these mechanisms toward health services. For example, policy that removes soft drink and candy sales from schools must consider lost revenue from these unhealthy but lucrative structures within the school system.

Various health-related patterns emerge from these interactions. For example, certain human-activity patterns negatively alter natural environmental patterns, which in turn influence human health patterns. Gordon's (2016) assessment framework focuses on 11 health-related functional patterns that assume community and environment interaction from a systems perspective.

Community From a Developmental Perspective

A framework based on developmental theory can also be used to identify existing or potential health problems for particular age groups in communities. Community nurses, focusing on the total community population, use a developmental, age-correlated approach to identify health-promotion and health-protection activities.

Nurses identify age-related risks at each life stage, taking steps to maximize wellness and health promotion as a lifelong concern (US Department of Health and Human Services, 2015). For example, adolescent single mothers of infants, at risk both emotionally and physically of medical problems, require parenting skills. Accidents are the greatest threat to children's health; therefore accident-prevention activities become a priority for communities with a young population and with adolescent mothers. Age-related risk factors (see Chapters 6 and 7) associated with individuals and families can be extended to include community groups based on the demographics of the community.

Community From a Risk-Factor Perspective

Risk factors associated with disease, illness, and death rates, although not causally associated with them, predict the likelihood of a particular adverse health condition in communities of interest (US Department of Health and Human Services, 2015). Risk factors include a combination of demographic, psychological, physiological, and environmental characteristics (or they may include a single characteristic). The influence of various risk factors differs from person to person and from group to group because of genetic composition, geographical location, lifestyle patterns, resources, socioeconomic status, education level, and community, neighborhood, or environmental variation (Box 8-2: Genomics and Community Assessment). For example, age, sex, race, geographical location, consumption pattern, or lack of health services may be considered risk factors, because one or more may contribute to disease or death and place the population sharing them at risk (Box 8-3: Research for Evidence-Based Practice). Some groups may be at high risk from a single risk factor, such as insufficient immunizations or exposure to asbestos. A combined potential for adverse health effects exists when many risk factors are present, because they interact in multiple ways and synergistically influence each other.

Box 8-2

Genomics

Community Assessment

Combinations of genetic, individual, and environmental factors interact to affect the risk of and/or protection from many chronic disorders, such as diabetes, Alzheimer disease, cardiovascular disease, and depression. Genetic modifications at both the individual

level and the community level impact these disorders. Moreover, these disorders modify genetic expression in both individuals and communities. Exchanges between the environment and genetics alter manifestations of these complex disorders. In contrast, manifestation of the disorder alters the environment and genetics. Community environment may influence mental health issues such as depression (Ware et al., 2016). Socioeconomic factors, chronic stressors (violence, unemployment, visual appeal), and community cohesion provide general measures in many studies.

In their study about predicting depressive symptoms, Ware and colleagues (2016) describe findings from studies linking community measures with genetic predictors of depression or depressive symptoms. The studies explored to provide support for their research included gene (serotonin transporter gene [5-HTT] promoter variant) interactions with the environment. The designs included only narrow individual-level samples or the wider county-level samples, rather than smaller less heterogeneous community samples. The findings from these few studies include gene interactions with environmental factors, such as a personal history of stressful life events, the proportion of individuals receiving public assistance (county level), county-level infant mortality rates, and county-level crime rates. These findings indicate that different risks of depression exist for different genotypes depending on their individual environment and their broader environment.

Use of phenotypic approaches to sample selection (depression symptoms) rather than diagnosed depression increases the sample size and extends the research to genome-wide/gene-region analysis rather than candidate gene analyses (Ware et al., 2016). Gene-region analysis explores the effects of genetic variability on phenotypic variability. Important genetic predictors have already been identified by analysis of genetic regions. Genetic predictors for numerous disorders have been identified after single nucleotide polymorphism (SNP) analysis revealed no statistically significant associations. Predictors for disorders such as bipolar disorder, coronary artery disease, hypertension, Parkinson disease, amyotrophic lateral

sclerosis, Crohn disease, rheumatoid arthritis, type 1 and type 2 diabetes, and age-related eye disease arose from the analysis of gene regions rather than SNPs (Peng et al., 2010).

The Multi-Ethnic Study of Atherosclerosis, a longitudinal cohort study, included six sites participating in the National Institutes of Health (NIH) SNP Health Association Resource (SHARe) project (http://www.nhlbi.nih.gov/research/resources/genetics-genomics/share). Approximately 1 million SNPs were genotyped, and the use of programs available from the NIH increased the number of available SNPs to about 2.5 million markers.

Ware and colleagues (2016) provide evidence to support SNP interactions in gene region 9 neighborhood index score (G 9 NIS) of depressive symptoms within the neighborhood level. This significant neighborhood gene region involves regulatory function of depressive symptoms. The gene-expression foundation for regulation of depression may be established early in life, with changes in depressive symptoms later in life. Molecular-level adaptation and brain response to local stimuli may depend on G 9 NIS changes. These community-level interactions in the G 9 NIS region may interact to influence depressive symptoms.

This novel study explored the influence of gene-region interactions on depressive symptoms and supports the idea that community or neighborhood context may interact with genetic factors in shaping depressive symptoms. Replication in other samples is necessary before firm conclusions can be drawn.

Box 8-3

Research for Evidence-Based Practice

Associations Among Parent/Peer Relationships and Individual Characteristics of Children

Salzinger and colleagues (2011) use socioecological theory as a foundation to explore associations among parent/peer relationships and individual characteristics in their sample of 667 children. Three rounds of data were collected over 3 years. Each round consisted of a 45- to 90-minute interview with the guardian of the child. Instruments were used to measure internalization of problems (depression, anxiety), externalization of problems (aggressive behavior), exposure to community violence, exposure to family violence, attachment to parents, attachment to friends, delinquency of friends, self-reported competence, moral disengagement (justification for the use of aggression), household dysfunction, and mental health of guardians. The consent process explained that counseling services would be available and child abuse would be reported. Stepwise hierarchical linear regression was used to analyze the data. High exposure to violence was associated with little protection from normally protective factors (e.g., attachment to parents) compared with low exposure to violence. In the low exposure to violence setting, peer protective factors (e.g., friends) were effective. Less internalizing of problems was independently associated with individual competence. Externalizing problems was independently associated with variables from all domains, and exposure. Parent attachment and other protective factors were associated with decreased problems, whereas increased problems were associated with risk factors, such as a friend's delinquency.

In a meta-analysis of the research literature on peer attachment and youth internalizing problems, Gorrese (2016) reported that Salzinger and colleagues' (2011) research clearly delineated the links between the quality of peer attachment relationships and internalizing symptoms over time. Gorrese's (2016) meta-analysis provides additional evidence for the implementation of community violence reduction, health-promotion, and health-prevention programs that emphasize and promote protective factors with parents and peers.

Initiating such programs may decrease adverse behavioral outcomes in adolescents.

From Gorrese, A. (2016). Peer attachment and youth internalizing problems: A meta-analysis. *Child & Youth Care Forum*, *45*(2), 177–204; Salzinger, S., Feldman, R. S., Rosario, M., & Ng-Mak, D. S. (2011). Role of parent and peer relationships and individual characteristics in middle school children's behavioral outcomes in the face of community violence. *Journal of Research on Adolescence*, *21*(2), 395–407.

Communities therefore experience substantial variability in health conditions in regard to both incidence and susceptibility. Risk-factor theory views health and disease as multifactorial, with cause attributed to no single risk factor. For example, risk factors such as air pollution, smoking, and forms of radiation in various combinations may be related to high rates of lung cancer, emphysema, and bronchitis in a community. The potential to control risk factors and to provide relevant health-related resources forms the basis for health-promotion and health-protection activities.

Gordon's Functional Health Patterns: Assessment of the Community

A variety of functional health pattern assessments are used with communities. Nurses use Gordon's (2016) functional health reference assessment as exemplified in this chapter or other assessments described in the literature.

Health Perception–Health Management Pattern

The health perception–health management pattern identifies data about community health status, health-promotion and disease-prevention practices, and community members' perceptions of health (Gordon, 2016). Residents may perceive a substance abuse problem in adolescents or a high rate of unwanted pregnancies, breast cancer, or sexually transmitted disease as concerns. Community health nurses provide data to address perceived health issues and develop community health management plans. For example, national data provide evidence for the extent of the perceived health issue of increases in their community's injection drug use. Injection drug use has declined in Canada (Roy et al., 2016); however, US data indicate increases in heroine use (Jones, 2013; Jones et al., 2015). The annual average rates of past-year heroin use in people aged 12 years or older nearly doubled from 2002 (1.6 per 1000) to 2013 (2.6 per 1000) (Jones et al., 2015). These data exceed the number of fatalities from motor vehicle accidents (US Department of Transportation National Center for Statistics and Analysis, 2008, 2012). Community partners compare these data with local data to determine public health issues to pursue.

Valuable information can be elicited by nurses conducting focus group discussions and by interviewing key community members about their health concerns and issues. Mortality and morbidity statistics and other public health information sources provide measurement data (see Chapter 2).

Nutritional-Metabolic Pattern

The nutritional-metabolic pattern identifies data relevant to community consumption habits as reflected in accessibility and availability of food stores and subsidized food programs for infants, children, and older adults. Community well-being, which depends on adequate dietary habits, food intake, and supply of nutrients, is influenced by culture, the presence or absence of kitchen facilities, and adequate plumbing.

Community assessment includes the collection of data by driving or walking through the community while using all five senses; it provides information about grocery stores, fast-food establishments, ethnic shopping facilities, and street corner vendors. Even affluent and developed countries contain areas without adequate access to food, or "food deserts," places where fresh food is not available. Income and food insecurity are highly correlated. Urban food insecurity (15% of city dwellers) in the US has grown with the growth in the urban poor population. As less than 2% of inhabitants still farm, movements to respond to food insecurity and access have evolved, promoting strategies such as backyard gardening, community gardening, community-supported agriculture, or local markets (Clendenning et al., 2016). Government programs, private soup kitchens, and food donations by houses of worship also provide information about nutritional patterns of communities.

Elimination Pattern

The elimination pattern identifies environmental factors, including exposure to pollutants in the community through contaminated soil, water, and air, and the food chain. This pattern further classifies environmental factors into the two broad categories—physical and biological. Alterations in environmental processes threaten the health and integrity of communities, necessitating health-promotion and health-protection activities. For example, humans eliminate most endocrine-disrupting chemicals, pharmaceuticals, and personal care products into the environment (Noguera-Oviedo & Aga, 2016).

Antibiotics and hormones from animals and fish also contaminate the environment. Groundwater, drinking water, surface water, and treatment plant effluents can be affected. Furthermore, some contaminants transform into contaminants that are more toxic than the original substance. For example, the antiviral acyclovir is excreted as a transformed product that is more toxic than the original drug (Schlüter-Vorberg et al., 2015).

Physical agents include geological, geographical, climatic, and meteorological aspects of the community. Certain population groups are particularly susceptible to acute respiratory disease and aggravated asthmatic episodes when the air quality is poor (Solomon et al., 2016). For example, when schools are located in high-pollution or high-traffic areas, children are exposed to polluted air. In addition, when home cooking devices pollute home air, families are exposed to polluted air (Pillarisetti et al., 2016). Use of solid fuel combustion such as wood or coal for cooking inside produces polluted home air. Community health nurses can use the Household Air Pollution Intervention Tool to plan interventions (Pillarisetti et al., 2016). Depending on resources, community collaborations, and partnerships, the community health nurse may use a variety of possible interventions to eliminate home air pollution from solid fuel cooking indoors. These interventions include simple chimney stoves with adequate exhaust, stoves with fan-assisted combustion, and/or clean fuel (Pillarisetti et al., 2016).

The geographical locations of communities, and major waterways, highways, or mountains located within communities, act as barriers to access to health facilities. Inaccessibility of health care services also hinders health in at-risk groups. Knowledge of climatic conditions provides clues to susceptibility to illness resulting from temperature or humidity in certain populations.

Biological agents include living things—such as plants, animals and their waste products, disease agents, microbial pathogens, and toxic substances—that can be hazardous to health. For example, Lyme disease, viral hepatitis, pneumonia, influenza, and the large number of diseases associated with childhood continue to be threats to

community health. Observation, focus groups, and interviews with key community members reveal information concerning elimination patterns. The Environmental Protection Agency (http://www.epa.gov/) and the Centers for Disease Control and Prevention (http://www.cdc.gov/) provide excellent resources for community health nurses.

Activity-Exercise Pattern

The activity-exercise pattern identifies physical activities and recreational options within communities. Science and technology have increasingly influenced productivity while simultaneously reducing or eliminating physical work. Consequently, physical activity no longer occurs during the work day for most community members, leaving leisure time as the only time for physical activity. Physiological evidence demonstrates that physical activity improves many biological measures associated with health and psychological functioning. Regular physical activity and musculoskeletal fitness are important for healthy, independent living as people grow older. Physical activity reduces the risk of many diseases, including obesity, heart disease, hypertension, cancer, osteoporosis, and diabetes mellitus.

Observation, focus groups, and interviews provide clues to a community's ability to provide cultural and recreational activities (Figure 8-3). Furthermore, noting whether the community has evidence of recreational facilities or is a “built community” with physical activity options (such as bike/walking trails), assessing transportation options, and observing community development that encourages walking should be included in the community assessment of the activity-exercise pattern.

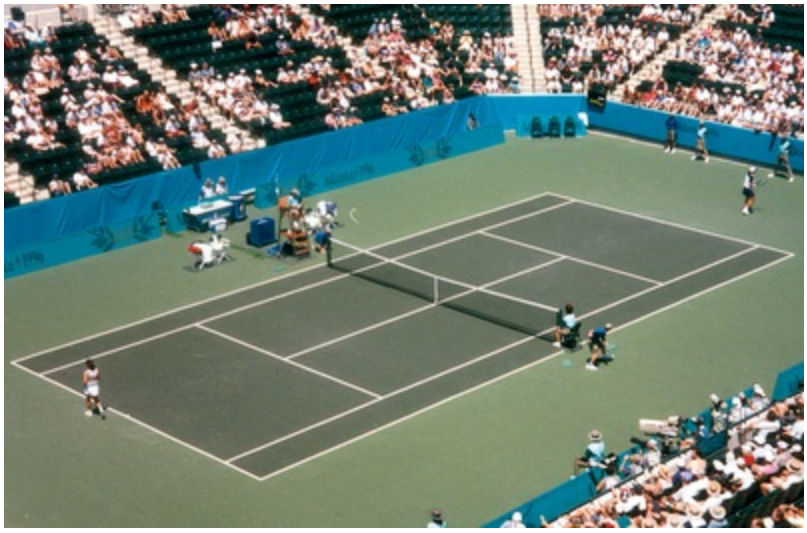

FIGURE 8-3 The activity-exercise pattern identifies a community's physical activities and recreational options.

Sleep-Rest Pattern

The sleep-rest pattern identifies a community's rhythm of sleeping, resting, and relaxing. Some towns never close, with stores, traffic flow, and recreational facilities operating during both day and night hours. This ongoing activity produces unpleasant disturbances, such as unwanted noise that may be harmful to community well-being. Excessive noise from highways or airplanes produces physiological or psychological problems eliciting responses ranging from mild irritation to pain or permanent hearing loss. Although noise cannot be eliminated, efforts to minimize and control it are possible. Observation, focus groups, and interviews provide clues to this pattern.

Cognitive-Perceptual Pattern

The cognitive-perceptual pattern identifies information about problem-solving and decision-making within communities. Systems depend on decision-making and resource allocation processes for survival. Communities require functional decision-making bodies to ensure adherence to rules and attainment of goals. Individual patterns

and environmental patterns connect with important implications for community health. Community assessment includes appraisal of interaction with the environment, as in the participatory processes of community-based system dynamics. The effectiveness of the strategies used depends on a collaborative evolution and long-term commitment of the nurse in the community (Frerichs et al., 2016).

One strategy, bargaining, offers communities a plan to exchange resources for health service. For example, a community that owns a mammography machine but has no primary care facility might negotiate with another community to provide mammography for primary care services in return. Strategies using outside authority (legal bureaucratic methods) ensure compliance through rules and structures. In this case, states may mandate that communities maintain certain health standards. For example, a law may require all schoolchildren to be immunized against specific diseases before they enter public school. Cooperative strategies promote health when members share common goals (Andrews et al., 2012a). For example, community residents may unite to oppose a chemical landfill that is a health hazard.

Convincing people to comply because they hold some loyalty in the situation or relationship is another method that mobilizes communities. For example, community residents might expend a great deal of effort and money to retain a particular health clinic because of loyalty to the agency. Identifying decision-making patterns used by communities provides clues about health priorities and values, as well as matches and mismatches between existing circumstances, health goals, and planning strategies. Data can best be obtained by observation, focus groups, and interviews.

Self-Perception–Self-Concept Pattern

The self-perception–self-concept pattern identifies self-worth and personal identity of communities. Characteristics such as image, status, and perceived competency with problem-solving indicate community self-concept. Housing conditions, buildings, and cleanliness reflect community image. School systems, crime rates,

accidents, and opinions about whether the community is considered a good place to live suggest community perception of self-worth. Competency with social and political issues as well as community spirit creates positive self-evaluation. Community pride facilitates development of innovative health programs. Emotional tone (fear, depression, or positive emotional outlook) relates to findings in other pattern areas. For example, tensions in the cognitive-perceptual pattern (conflict between groups concerning health issues) may explain a general feeling of fear among the residents. Data are obtained through observation, focus groups, and interviews.

Roles-Relationships Pattern

The roles-relationships pattern identifies communication styles along with formal and informal relationships. Of particular concern are roles and relationships affecting community ability to realize health potential. Patterns of crime, racial incidents, and social networks form indices of human relationships in communities. Publicizing health promotion becomes more effective when patterns of official communication are used. Health program success depends on support from prominent community members. Community members involved in health programs help identify other key community leaders. Use of media and other mass information programs improves communication, the flow of health information, and the number of community members reached. Interviews, television, the Internet, and newspapers are examples of ways to obtain and convey information.

Sexuality-Reproductive Pattern

The sexuality-reproductive pattern identifies reproductive data of communities, which is reflected in live birth statistics, mothers' ages, ethnicity, and marital status. This information provides clues to the health-promotion needs of a particular community group. Premature infant rates, low-birth-weight infants, and abortion rates, as well as neonatal, infant, and maternal death rates reflect reproductive patterns of communities. Such information identifies at-risk groups on

the basis of particular characteristics associated with these rates. Mismatches between existing health services, health education, and community health statistics also indicate health concerns. Availability of sex education in schools, the levels of spousal and child abuse, and the number of sex-related crimes also indicate health-promotion issues. Minutes of meetings, health records, statistical data, and public documents provide sources for these data.

Coping–Stress Tolerance Pattern

The coping–stress tolerance pattern identifies the community's ability to cope or adapt. Communities respond to stress in different ways, some of which might threaten their integrity. Community responses reveal the group coping patterns. Communities develop abilities to exchange goods, services, goals, values, and ideals to survive and to promote community health. Community efforts to obtain goods from the environment, contain goods within the environment, retain goods within the community, and dispose of goods play significant roles in influencing health. Examples of resources that communities obtain from the environment to promote health include local, state, or federal funding; health services; health-related workforce personnel; new knowledge; and technological advances. Some communities obtain abundant health care services; however, primary services often remain inadequate or nonexistent. Lack of available health services, or lack of ability to obtain them, characterizes community health need. Examples of problems communities may attempt to control include sex-related crimes, diseases, substance abuse, industry, hazardous waste in the water supply, and noxious chemicals in the air.

Community coping patterns aim to retain certain health-protection services, such as immunization services for children and adequate health facilities. Coping efforts may also include strict zoning laws and housing codes or certain values such as sex education within the home. Expendable goods of communities include industrial and human wastes. Data can be obtained through minutes of meetings, public documents, health surveys, statistical data, and health records.

Values-Beliefs Pattern

The values-beliefs pattern identifies the community values and beliefs. Such information provides clues for health-promotion and health-protection efforts valued by the community. Values underlie decisions about community health education and tax support for schools, hypertension screening for the public, disease-prevention programs, or well-child clinics. Traditions, norms, and cultural and ethnic groups share values and beliefs in communities. Data can be obtained through focus groups and through interviews with key community members and health-related personnel.

Analysis and Diagnosis With the Community

Analysis refers to data categorization and pattern determination. Data synthesis and organization occur to ascertain patterns of health activities and trends. An example of a clinical scenario about a particular community is presented in the case study and care plan at the end of this chapter. Decision-making and judgment inherent in the nursing process become most important during the analysis and diagnostic phases. Table 8-2 presents an example of one way to organize community data using Prochaska's stages of change (Pender et al., 2014).

TABLE 8-2

Stages of Change

Stages	Interventions
Precontemplation	Provide information (identify risk factors) Raise doubts about current behaviors and future outcomes
Contemplation	Discuss risks of not changing Discuss benefits of changing
Planning or preparation	Help plan phases of change Help implement phases of change
Action	Help develop strategies to prevent relapse, emphasizing self-efficacy Offer encouragement
Maintenance	Highlight past successes and future benefits

Modified from Pender, N. J., Murdaugh, C. L., & Parsons, M. A. (2014). *Health promotion in nursing practice* (6th ed.). Upper Saddle River, NJ: Pearson.

Organization of Data

Charts, figures, and tables graphically display population distributions, morbidity and mortality data, or vital statistics to pinpoint significant community concerns with actual or potential health problems along with health-related responses to these concerns. Another valuable organizational technique—mapping—

facilitates data analysis. For example, a series of maps gathered with use of technology such as GIS displays data that change over time. Analysis of several variables occurs simultaneously. Overlap of the locations of environmental hazards, densely populated areas, health-promotion services, and major highways becomes apparent. Poor environmental conditions; the distribution of illness, disease, and death rates; and accessibility of health-protection and health-promotion activities for the population appear at a glance with dotted scatter maps. Use of maps requires knowledge about the community's population base. Less-populated rural areas with fewer health facilities or fewer neonatal deaths in a community with fewer women of childbearing age are examples of how population statistics influence interpretation of mapping techniques. Use of theoretical frameworks for community health and Gordon's (2016) 11 pattern areas facilitates analysis of community data. Several guidelines, presented next, help community nurses analyze population data. Analysis often supports the need for further data collection.

Guidelines for Data Analysis

Check for Missing Data

The complexity, size, and number of community characteristics prohibit all possible facts about the health-related pattern areas being gathered; however, missing or insufficient data that indicate areas for further assessment should be identified. Additional assessment may determine specific approaches or a particular **community diagnosis.** Examples of missing data in community assessment include pollution indices, links between health resources and population groups, accessibility to resources, and morbidity statistics. Dates for census data used should be noted.

The nurse examines community data for incongruities and conflicting information. For example, a key community official might deny the existence of pollutants in the water supply, whereas newspaper reports of health department water analysis findings indicate otherwise. The nurse evaluates such inconsistencies before

identifying existing or potential health concerns.

Identify Patterns

Clues about a **community pattern** emerge from subjective and objective data gathered. During this stage, community nurses make decisions, begin to formulate diagnostic hypotheses (ideas and tentative judgments about possible health concerns), identify community groups that might be at risk, and establish probable causes or relationships. Ideas generated from this activity direct the search for additional clues in the data to confirm, reject, or revise hypotheses. Judgments about hypotheses continue to support patterns in the data.

To narrow the huge list of possible community health-promotion and health-protection concerns, community nurses formulate broad problem statements based on the health-related pattern areas (Gordon, 2016). For example, the community nurse differentiates among elimination problems (e.g., noxious chemicals), coping and stress-tolerance problems, and health perception–health management problems (e.g., high teenage mortality rate from motor vehicle accidents). Developing these general categories facilitates analysis.

Apply Theories, Models, Norms, and Standards

Analysis of community data requires extensive knowledge of developmental, age-related risks, as well as theories and concepts of nursing, public health, and epidemiology. Such a broad foundation enables nurses to identify additional clues in health-related patterns that contribute to community nursing diagnoses and intervention. Developmental approaches form a basis to identify groups with potential health concerns. Age groups differ in susceptibility; therefore nurses examine community resources directed toward highly susceptible groups. For example, community data that show increases in the number of live births among older women indicate a need for health-promotion services for this group. If community data show increasing numbers of aging citizens, nurses explore the

availability and accessibility of existing health services for this older group.

Analysis of data for common personal or environmental characteristics also occurs. For example, select groups may be at risk on the basis of a shared health concern, such as substance abuse, lack of immunizations, unsafe housing conditions, high exposure to asbestos or noxious chemicals, or inadequate health services. Shared characteristics, such as race or ethnicity, provide clues to susceptibility and the need for screening activities. For example, black populations warrant screening for hypertension. Additionally, if a fluoridated water supply is unavailable, additional intervention to prevent dental caries in children is justified. In addition, community literacy contributes to health-promotion activity development methods used by nurses to establish educational programs. A low literacy level limits the ability to use all available resources.

Environmental information is readily available on the Internet. Databases and search engines provide useful information about environmental hazards and other environmental problems in communities. Prevention of disease worldwide depends on the dissemination of global environmental health information (US Department of Health and Human Services, 2015). Analysis of data relies on standards developed nationally or globally. For example, community data regarding air quality can be compared with state or national ambient air quality standards to determine health. In this context, the term **ambient** refers to outside air in a town, city, or other defined region. In the United States, air-monitoring stations are generally located in urban and rural areas within each state. One source for air quality information is the CHARTing Health Information for Texas, which is maintained by the University of Texas Health Science Center at Houston School of Public Health. The goal of this center is to serve as a resource in Texas for publicly available data to use for analysis and research. Data and links to other sites are continually monitored and updated (University of Texas Health Science Center at Houston, 2012). Current information about community resources enables more effective strategies to prevent risk

factors and avoid health problems. Internet access facilitates identification of gaps in health-promotion and health-protection services.

Identify Strengths and Health Concerns

Interpretation of community data occurs with regard to community concerns, community strengths, and feasibility studies. Community nurses make judgments and inferences about community health, community responses to health situations, and population needs. One approach assumes health concerns exist unless assessment data indicate otherwise (Gordon, 2016). Other systems of assessment base decisions on community strengths. With the problem-focused assessment of health concerns, nurses make diagnoses based on summarized data using the nursing process, which results in one or more of the following determinations:

- No problem exists, but providing health-promotion or health-protection services may address a potential health concern. For example, providing health education in a high school could offset a potential for increased sexually transmitted disease in the high school population.
- A problem exists but is recognized by community members or health-related professionals with effective strategies for problem-solving; for example, flu immunizations.
- A problem exists that the community recognizes, but resources are inadequate or the community has not responded. Assistance is needed; for example, highway traffic noise.
- A problem exists that the community recognizes but cannot cope with at this time, such as a lack of fluoridated water systems. Dentists, nurses, and nutritionists could be assigned to assist the community in resolving actual problems of dental caries.
- A problem or potential health concern exists that needs further study; for example, lack of sidewalks.

Use of strength-based approaches to assessment emphasizes

strengths and integrates health-promotion and health-protection activities into a person's plans. For example, a community may have nutritional feeding programs for older adults, women, and children that are underutilized. Community members may not use them because communication is inadequate. Examples of community strengths and concerns are shown in Table 8-3.

TABLE 8-3

Examples of Community Strengths and Concerns

Strengths	Concerns
Well-child clinic available	Unavailable
Feeding program accessible to older adults	Inaccessible
Sex education in schools acceptable	Unacceptable
Family planning services accessible	Inaccessible
Fluoridated water system	Nonfluoridated water system
Open communication	Dysfunctional communication
Interagency cooperation	Dysfunctional transactions
Adequate kitchen and plumbing facilities	Inadequate
High interest of key leaders in health promotion	Lack of interest

Identify Causes and Risk Factors

Data are examined for factors or characteristics that contribute to identified potential and existing health-related concerns. Nurses make inferences about population groups and identify risk factors. Identification of risk factors guides community nursing actions. Some risk factors signify immediate health concerns, such as a polluted water supply, whereas other risk factors indicate potential problems, such as lack of knowledge of childhood disease prevention. Nurses consider whether **community risk factors** can be altered, eliminated, or regulated through nursing actions. Nurses modify risk factors when possible by using strategies such as health education (Box 8-4: Diversity Awareness).

Box 8-4

Diversity Awareness

Comparing Poverty Rates by Racial and Ethnic Categories

The United States uses the Current Population Survey to assess the labor force, but this survey also provides a broad-based database that includes demographic data facilitating comparison among groups (US Census Bureau, n.d.). According to the 2007–11 American Community Survey, the poverty rate (14.3%) increased by 2.3% from the level in 2007 (US Census Bureau, n.d.). Racial and ethnic disparities in poverty rates persist, with the highest rates for American Indians and Alaska Natives (27%). The next highest rates of poverty, listed in order from highest poverty rate to lowest, are for blacks or African Americans (25.8%), Native Hawaiians and other Pacific Islanders (17.6%), and the Asian population (Korean [15%], Vietnamese [14.7%], and Filipino [5.8%]). Among Hispanic subpopulations, the poverty rates ranged from a low of 16.2% for Cubans to a high of 26.3% for Dominicans. Non-Hispanic whites continue to maintain the lowest poverty rate among the racial ethnic data collected (9.9%).

Poverty experiences place these populations at risk for many health problems, such as developmental delay, asthma, and heart disease. Identifying harmful social determinants of health during community assessment facilitates health promotion for communities experiencing poverty (Chung et al., 2016). Assessment of the community should explore whether organizations exist to assist with food access, child health insurance options, employment opportunities, restraining orders, and securing safe housing. Access to health services, particularly mental health services, should also be included in assessment of impoverished communities. Furthermore, community members who remain informed about the unique resources available locally offer important information for planning care and referral to community-based programs.

Local health agencies, nonprofit groups, and community resource lists may provide additional information about resources available within the community. The community assessment gathers

information about the issue encountered most frequently. Other issues may be less common, but because of their severity should be assessed, such as the incidence of child maltreatment.

From Chung, E. K., Siegel, B. S., Garg, A., Conroy, K., Gross, R. S., Long, D. A., et al. (2016). Screening for social determinants of health among children and families living in poverty: A guide for clinicians. *Current Problems in Pediatric and Adolescent Health Care, 45*(5), 135–153; US Census Bureau. (n.d.). Current population survey. http://www.census.gov/programs-surveys/cps.html.

Community Diagnosis

Community assessment, as previously described, culminates in nursing diagnoses. The following components are included in the community diagnosis process: community situations or states within a population or population group; data collection using some combination of observation, focus groups, interview, and measurement; a framework; existing or potential health concerns; risk factors related to health concerns; and potential solutions through nursing actions. Diagnoses form the basis for planning, implementing, and evaluating solutions to health concerns (Gordon, 2016). Box 8-5: Quality and Safety Scenario and Box 8-6: Innovative Practice provide an overview of how workplace violence contributes to quality and safety and how leaders might intervene to prevent or diffuse violence.

Box 8-5

Quality And Safety Scenario

Workplace Violence

Targets for violent acts may be places where people work to support their families. Workplace violence was once considered isolated, unplanned incidents that fell under the jurisdiction of the federal Occupational Safety and Health Administration (OSHA). Currently, workplace violence prevention and preparation often also include external threats of terrorism. The following are some recommendations to minimize workplace violence:

- Encourage public awareness campaigns.
- Develop workplace policies and plans.
- Adopt a zero-tolerance workplace violence policy.
- Apply preventive law enforcement policies.
- Perform background checks on employees.
- Study government agencies that make workplace violence a priority.
- Provide proper training for employees, supervisors, and managers about warning signs of violent behavior.
- Encourage a workplace culture that facilitates health relationships, creative problem-solving, and voicing concerns while discouraging a hostile environment.
- Expect nonautocratic leadership styles.
- Prevent/minimize negative coworker behavior.
- Encourage social support (listening, recognition) for employees to succeed at their work.
- Implement strategies to minimize absenteeism, turnover, and low performance.
- Implement strategies to encourage participatory management.
- Ensure protection of the abused person when domestic violence or stalking occurs in the workplace.
- Develop and distribute clear and comprehensive legal and legislative guidelines.

- Evaluate programs and strategies after they have been implemented.

Suggestions for approaches included the following strategies:

- Educational efforts should reflect cooperative efforts by government agencies, major corporations, unions, and advocacy groups, with OSHA acting as a facilitator and coordinator.
- Enact multidisciplinary no-threats/no-violence policies and prevention plans.
- Violence prevention training should occur regularly and include practicing the plan.
- The work space and policies should provide a physically secure work environment.
- Preventive measures should be established, including documenting incidents, planning antiviolence strategies, and conducting threat assessments.
- Systems should be developed for the monitoring of incidents of workplace violence.
- Resource lists should be maintained and include social service, mental health, legal, and other agencies that provide assistance.
- Training programs should extend community policing concepts to workplace violence. Government or private organizations should develop training materials for small employers. Employers should keep the abuser out of the workplace (e.g., screening telephone calls, making the victim's work space physically more secure, instructing security guards or receptionists).
- Employers should provide resources for emotional, financial, and legal counseling. Clear, comprehensive, and uniform legal

guidelines should be distributed widely.

- Incentives for employers should be identified and instituted.

Innovative Practice

Intervention Techniques to Prevent and Diffuse Workplace Violence

Lanza and colleagues (2016) reported their findings from a research study exploring the benefits of an innovative community intervention to prevent and diffuse workplace violence. The community meetings used a format (the violence-prevention community meeting) designed to minimize violence and promote nonviolent problem-solving and acting with civility. Their study included patients and staff on seven locked psychiatric units in the US Veterans Health Administration. During 21 weeks, each site had violence-prevention community meetings (VPCM) during the middle 7 weeks, with 7 weeks before the VPCM and 7 weeks after the VPCM. After the VPCM, aggression rates dropped. In addition to innovative strategies such as the VPCM, the following techniques may also be useful:

- Recognize warning signs, which include changes in mood, personal hardships, mental health issues (e.g., depression, anxiety), negative behavior (e.g., untrustworthy, lying, bad attitude), verbal threats, and history of violence.

- Do not limit at-risk behavior to a standard profile.

- Environments should be designed to detect signs of impending violence and to prevent violence with security cameras, key card access, administrative controls, and behavioral strategies.

- Reporting systems should be confidential and seamless.
- Stay calm; create a relaxed environment and speak calmly.
- Separate the individual from the group, if possible.
- Use nonthreatening body language; build trust and strengthen the relationship.
- Keep your verbal communication simple, clear, and direct; be open and honest.
- Reflect on the person's message to allow time for clarification, allow the person to verbalize, listen attentively, and stop what you are doing and give full attention.
- Ask for examples to help illustrate the points that are being made. Carefully define the problem, exploring it with open-ended questions.
- Silence allows the individual time to clarify thoughts.
- Monitor the tone, volume, rate, and rhythm of your speech.
- Seek opportunities for agreement.
- Be creative and open to new ideas.

From Lanza, M., Ridenour, M., Hendricks, S., Rierdan, J., Zeiss, R., Schmidt, S., et al. (2016). The violence prevention community meeting: A multi-site study. *Archives of Psychiatric Nursing*, *30*(3), 382–386.

Community diagnoses and problem structuring facilitate communication among community health professionals, team members, and community members through the use of clear and concise nomenclature with development of diagnostic categories using both inductive and deductive reasoning specific to community nursing (Frerichs et al., 2016). Diagnoses may be written or stated

according to the structural and functional aspects of a community.

Structural aspects include those related to the population, such as the demographic characteristics of groups with similar characteristics (preschool children, adolescents, or a high school population). Functional aspects include those related to the psychosocial, physiological, or spiritual health patterns, such as decision-making (cognitive-perceptual pattern) or communication links among health care resources (roles-relationships pattern). Functional health patterns guide data collection about health concerns and risk factors. Structural and functional aspects of the community provide a framework for diagnostic statements (see Chapter 6).

Planning With the Community

Community health planning begins with nursing diagnoses. Nurses design goals to resolve existing or potential health concerns. For example, high rates of childhood diseases in the community require goals aimed at decreasing rates. Identification of specific or potential health concerns with planned actions to achieve desired **community outcomes** provides the framework and data for **community evaluation.**

Purposes

The following are major purposes of the planning phase:

- Prioritization of problems and identification of diagnoses through assessment
- Differentiation of problems resolved through nursing actions from those best resolved by others
- Identification of immediate, intermediate, and long-term goals, as well as behavioral objectives oriented to the community derived from the goals and specific actions to achieve objectives
- Formalization of a community nursing care plan (see the care plan at the end of this chapter) that includes written problems, actions, and expected behavioral outcomes

The planning phase culminates in a nursing plan that provides the framework for evaluation. Once developed, the plan is implemented. The costs associated with the delivery of health services and personnel, as well as the financial resources available, influence the priorities for implementation. Community values and the nurse's philosophy about people, health, the community, and nursing also influence implementation. High-priority issues often include infectious agents, sexually transmitted disease, alcohol and drug use, smoking, inadequate nutrition, inadequate infant and child care, high death rate from motor vehicle accidents, texting while driving,

heroine overdose, and unwanted teenage pregnancies.

Community participation in health planning facilitates effective assignment of priorities. As health service recipients, community members strive for reasonably priced, high-quality services. Residents aim to acquire appropriate benefits for the needs and concerns of the population. Communication and the rationale for designating priorities help to resolve differences in opinion.

During the planning phase, nurses determine those problems most amenable to **community nursing intervention,** behavior implemented by the nurse to fulfill a health goal of the community. Community nurses differentiate problems nursing can resolve from those health concerns that could best be managed by community members, referred to health-related professionals, or handled with community support. Nurses refer problems related to the presence of rodents, poor sanitation conditions, or the absence of community recreational facilities to appropriate community leaders or agencies.

Community nurses focus on determining goals, developing measurable behavioral objectives, and designating actions to achieve expected outcomes. Nurses describe specific behaviors intended to reach projected outcomes. Evaluation includes appraisal of the effectiveness of nursing actions. Health planning emphasizes promoting and protecting population health; therefore problems, solutions, and actions are defined at the group level. Community nurses plan and implement health plans for groups, such as school-age children, and facilitate development of health-promotion services for all residents. Nurses frequently act as change agents by taking responsibility for influencing health patterns and behavior. Decisions about health interventions stem from community nurses' appreciation of human behavior and principles of planned change.

Planned Change

Planned change results from efforts by individuals or groups, and involves fundamental shifts in behavior (Pender et al., 2014). Individuals act as agents of their own health conditions. Community health objectives often depend on active decisions by individuals to

change their lifestyles (reducing alcohol consumption or quitting smoking). Efforts to influence and reinforce changes in community health behavior become the central focus of effective risk reduction programs (Brown et al., 2016).

Studies attempt to explain why some groups of people effectively participate in certain health programs or make lifestyle changes, whereas others do not. Early work by Rosenstock, who developed the health belief model, has evolved to models such as those by Pender and Prochaska used to explain and change health-promotion behaviors (Pender et al., 2014). These models identify critical concepts for understanding how individuals change their health behavior. Rosenstock's model includes the following four steps:

- Perceiving behavior as a health threat in terms of susceptibility and seriousness
- Believing the behavior is a threat to their personal health
- Taking action to adopt preventive health behaviors
- Reinforcing the new behavior

In Rosenstock's model, community members take a passive role at first, and then transition from passive to active between the second and third steps (belief to action). Ultimately, to improve community health through risk reduction programs, community members assume more responsibility for their own health, become more active in adopting healthy lifestyles, and monitor resources in the community to achieve healthy behaviors. In planning health-promotion activities, nurses consider effective strategies to motivate and support community transition from a passive to an active state.

Plans guide nursing actions. Nurses make additions and changes on the basis of community problems, resources, and problem resolution to maintain a viable plan. Table 8-1 provides one example of a community-oriented, health-promotion plan based on the goals recommended by the Surgeon General's report about health promotion and disease prevention. The report's general goal generates several specific objectives. Nursing diagnoses guide the direction of the objectives, including the risk factors to be addressed. Examples of

various rationales in Table 8-1 show how nurses incorporate important concepts of planned change into community-based health-promotion plans.

Communicating plans to other health professionals, community members, and key officials remains an essential aspect of planning. Unification of care systems and linkages through shared data entry, computerized documentation, and electronic medical records contribute to more streamlined and transparent communication and collaboration. Local newspapers, local bulletins, and school correspondence to parents provide avenues to communicate with the community about health-promotion plans. Other community-based actions, such as those for nursing involvement in prevention of alcohol abuse in the community, can be used. The various plans have been categorized according to the health patterns to show that a community problem can be approached from multiple directions. Feasible plans that are well formulated facilitate implementation (US Department of Health and Human Services, 2015).

Implementation With the Community

Implementation of the nursing process begins on the basis of the health-promotion and health-protection plans. In collaboration with community members or other health team members, the nurse tests feasibility and implements the plan. Involving key community members, in the assessment and planning process, is crucial for success. To ensure involvement, activities must be accessible. For example, schedule meetings in accessible areas, offer child care services, and provide light refreshments. Identify clearly what the community perceives as health-promotion needs. Maintain open communication—clear and correct information at regular intervals.

Intellectual, interpersonal, and technical skills of the community members facilitate the collaborative contribution. Community nurses often prepare community members with development of technical skills of community engagement and empowerment. Success also depends on the overcoming of expected resistance to change. Resistance to new health-promotion and health-protection activities, however, provides useful feedback to improve planning. People generally resist change to defend values that appear to be threatened by the change. Collaborating with communities initially facilitates change during the implementation phase. Table 8-4 lists factors that deter community participation. Informed nurses collaborate with community members throughout the process.

TABLE 8-4

Potential Sources of Resistance to Health-Promotion Programs, With Agent Responses

Source of Resistance	Response
Lack of communication about implementation of program	Communicate through community newsletter, newspapers, high school radio station, and posters
Misinformation regarding time and place of healthy activity	Disseminate valid information
Fear of unknown	Inform and encourage
Need for security	Clarify intentions and methods

No desired need to change behaviors	Demonstrate opportunity for change
Cultural or religious beliefs or vested interests threatened	Enlist key community leaders in planning change
Inaccessibility	Focus activities near the largest target population and in an area accessible by public transportation

Community nurses implement health-promotion and health-protection plans in multiple community settings (schools, industry, public and private health agencies, and ambulatory care settings) where population groups experience relatively good health. Nursing centers provide nursing faculty, staff, and students with unique opportunities to assess health and plan, implement, and evaluate care (including holistic health promotion and primary health care) for individuals, families, and communities with unmet health care needs (Harvey et al., 2012). Community assessment includes observation of reciprocal interaction between the individual and his or her environment, which is similar to those techniques used for individual and family health promotion assessment (see Chapters 6 and 7 respectively). Community assessment also commonly uses factors related to self-efficacy and Bandura's social learning theory to explain relationships between human behavior and the environment. The complexity of health actions differs from one community to another. Community advisory boards play a critical role in community planning. As plans evolve, nurses learn more about the community and their own responses, strengths, limitations, and abilities to cope or adapt (Subica et al., 2016). Although implementation takes an action focus, it also includes assessment, planning, and evaluation activities to monitor actions taken to resolve, reduce, eliminate, or control the health concern.

Evaluation With the Community

During the evaluation phase of the process, community nurses learn whether planned actions achieved desired outcomes. Communities and nurses determine progression toward goal achievement through methods that expand collaborations (Frerichs et al., 2016). Nurses take overall responsibility for the process; however, collaborating with community members and health team members in the process produces the most valid results. For example, if implemented plans intend to reduce the incidence of fatal motor vehicle accidents, nurses guide the process to obtain community indicators and outcomes data, requisite community actions, and expected outcomes achieved from joint collaboration with community stakeholders.

Nursing plans, which include nursing diagnoses, expected outcomes, and interventions, provide the evaluation framework. With a community focus, goals and objectives define the evaluation, considering how the community responded to planned actions. For example, if childhood disease rate reduction is expected to result from certain nursing actions, community responses before the actions are compared with those after the actions. Comparison determines the level of effectiveness (complete, partially effective, or ineffective) of the nursing actions to achieve the goal.

Community nurses approach the dynamic process of evaluation in a purposeful, goal-directed manner (Stanhope & Lancaster, 2015; US Department of Health and Human Services, 2015). Determining the effectiveness of nursing actions evaluates the degree to which goals are achieved. The frequency of evaluation depends on the situations, changes expected, and objectives. For example, an individual who is bleeding may need evaluation at frequent intervals, whereas behavioral changes in community groups occur slowly and require long-term evaluation methods. Evaluation intervals differ depending on immediate, intermediate, and long-range goals. The evaluation process continues until community goals are realized.

Evaluation results indicate the need for reassessment, revision, or

modification of plans. Community nurses reassess situations, plan new approaches, and implement and evaluate revised plans, creating the continual cycle of the nursing process. Self-evaluation determines strengths and weaknesses as well as ways the nursing plan could have been more effective or efficient. The quality of community health-promotion and health-protection efforts depends on the professional qualities of those providing the services along with effective use of the nursing process.

Workable, cost-effective programs of community health promotion are needed. Nurses play an important role in providing evidence to support effective community health plans. Historically, documentation of effective health-promotion activities has been limited (Maurer & Smith, 2014; Pender et al., 2014). Effectiveness is determined through research studies that include analyses and outcomes evaluation of home-based and community-centered nursing interventions designed to meet the needs of high-risk families, geographical communities, and vulnerable populations. For example, in a study of 679 women eligible for the Special Supplemental Nutrition Program for Women, Infants and Children, health-promotion strategies of nutrition, physical activity, and social support were used to reduce the incidence of depressive symptoms (Surkan et al., 2012). Surkan and colleagues (2012) demonstrated that health-promotion interventions delivered through home visits and telephone calls reduced the incidence of depressive symptoms at 15 months postpartum among low-income, ethnically diverse women. Such evidence-based practice and research helps to garner support for community health-promotion programs. The *Healthy People 2020* objectives include examples of national and state partnerships establishing health objectives and sustaining the initiatives (US Department of Health and Human Services, 2015).

Case Study

Community Efforts to Decrease Adolescent Pregnancy Rates

The community health nurse is facilitating a grassroots community group that is determined to decrease the adolescent pregnancy rate in the city. The community population hovers around 100,000. It is a community that lies on the Mexican border of the United States. The population is predominantly Mexican American, and there is a high poverty rate.

The schools offer health courses twice between seventh grade and twelfth grade. The only formal sex education provided occurs within the context of these two health courses. There is community opposition to increasing the amount of sex education in the curriculum. A community group that has researched the problem has decided to use a social marketing approach because of this community resistance.

Most of the materials reviewed do not address the cultural needs of the region. Many of the Spanish language materials use Spanish from countries other than Mexico. The situations posed in the audiovisual materials show people who the adolescents will perceive as different from themselves.

Reflective Questions

- How could the community group approach its goal to decrease the adolescent pregnancy rate in a manner that will be culturally competent?
- How might the community group approach this issue without the support of the school district?

Care Plan

Community Efforts to Decrease Adolescent Pregnancy Rates

***Nursing Diagnosis: Risk of ineffective community coping related to increased levels of teen pregnancy**

Defining Characteristics

- Absence of education or support for sexually active teenagers
- Absence of programs for pregnancy testing, counseling, or teaching young women to care for infants
- Absence of sex education in the home, school, and community
- Community conflicts over what to teach adolescent and preadolescent children about sex
- Failure of teenagers to perceive the long-term effects of having babies
- High incidence of infants who are born prematurely or with health problems
- High rate of teen pregnancy
- Lack of access to birth control pills or devices for teenagers
- Lack of community support for preventive sex education

Related Factors

- Community members' lack of knowledge about the causes of and contributing factors in teen pregnancy
- Inadequate community resources for preventing teen pregnancy
- Lack of adequate communication patterns and community cohesiveness regarding strategies to prevent teen pregnancy

Interventions

- Assess teenagers' knowledge of sex and sexuality to determine their

educational needs.

- Work with schools to develop pregnancy-prevention programs that provide adolescents with information about the risks, problems, and complications of early pregnancy.
- Work closely with individual adolescents who are pregnant to assess their needs and provide care.
- Implement an outreach and health-promotion program to raise community members' awareness of the need to approach teen pregnancy as a community problem. Consider taking the following five steps:
- Work with teachers, school psychologists, counselors, school nurses, students, and the parent-teacher association to determine the extent of the teen pregnancy problem.
- Encourage local youth groups, churches, and social service organizations to feature presentations on pregnancy prevention at their meetings.
- Contact representatives of local corporations to ask for funding for educational programs.
- Help community members (school nurses, counselors, and teachers) recognize adolescent girls who need counseling regarding such issues as peer pressure to be sexually active and the long-term consequences of pregnancy. Remind community

members of the importance of listening attentively and remaining nonjudgmental.

- Provide education on birth control measures (including abstinence from sex) and make this information available at school.

- Establish clubs for adolescent girls in the community. The goal of these clubs is to foster self-esteem. During club meetings, members should have the opportunity to openly discuss difficult questions, such as why girls consider a baby a status symbol and how to respond to peer pressure to be sexually active. Increasing self-esteem has been found to be the most effective way to reduce teen pregnancy rates.

- Encourage adolescents to participate in peer support networks where they can openly discuss social and dating pressure and other issues related to teen pregnancy, to allow them an opportunity to express their feelings openly and obtain support from peers.

- Encourage community members to establish school-based clinics in which teens can have access to reproductive system models, pregnancy tests, and nonprescription birth control measures to support the teenagers who make the decision to protect themselves from unwanted pregnancies.

- Develop a list of referrals for teenagers, such as hospitals with human sexuality courses, charities that provide prenatal care and childbirth services, women's clinics, and Planned Parenthood, to compensate for restricted access to information in the adolescent's home or school.

- Encourage community members to implement an information campaign to educate adolescents, parents, and community

members about the problems associated with teen pregnancy.

- Work with community members to evaluate the effectiveness of the teen pregnancy prevention program and assist in modifying it as needed to ensure its effectiveness and promote the program as a model for preventive health.

- Collect statistical data from the schools to analyze the teen pregnancy rates, to help evaluate the effectiveness of the prevention program.

Expected Outcomes

- Community members express awareness of the seriousness of the high adolescent pregnancy rate in their community.

- Community members express the need for a plan to reduce the prevalence of teen pregnancies.

- Community members develop and implement plans to prevent teen pregnancy.

- Community members evaluate the success of the plan in meeting goals and objectives.

- Community members continue to revise the plan to prevent teen pregnancy as necessary.

*NANDA Nursing Diagnoses—Herdman, T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Risk factors, injury, and disease are not inevitable events experienced equally among a community's members. Effective community nurses understand the dynamic and complex nature of communities (Figure 8-4). Nurses use various theoretical frameworks to assess health-related patterns, health concerns, and health action potential and to implement the nursing process within communities. Collection and analysis of community data identify susceptible subpopulations. Planning contributes to the development of effective and efficient health-promotion and health-protection services. The nursing process enhances the efficacy of planning activities.

FIGURE 8-4 Communities come together for the enjoyment of one of their traditional holidays. (From iStockphoto/Thinkstock.)

Many communities experience obvious deficiencies in health services that warrant health planning action. Community nurses play a significant role in health planning directed toward reducing the risks associated with disease, premature death, and injury as well as health promotion among community members. Nurses use principles

of planned change to increase community awareness of health, promote healthy behaviors, and encourage participation in preventive health services. The complexity differs from one community or geographical area to another. Community nurses connect health-promotion actions to specific community phenomena, providing scientific evidence to support nursing actions in the community.

10 Health Education
11 Nutrition Counseling for Health Promotion
12 Exercise
13 Stress Management
14 Complementary and Alternative Strategies

Screening

Elizabeth Connelly Kudzma

OBJECTIVES

After completing this chapter, the reader will be able to:

- Discuss screening and its role in secondary prevention and health promotion.
- Analyze criteria to determine if a disease has evidence-based guidelines for screening.
- Identify health care, economic, and ethical implications related to the screening process.
- Discuss how collaborative community and national partnerships and policies assist in the development and implementation of a screening program.
- Describe elements of the nursing role in the screening process.

Think About It

Screening Then and Today

In the 1920s, educators started to investigate the concepts of intelligence quotient, lower intelligence, and mental handicaps. Intelligence categories were separated numerically, and "cretin" became a medical term used to describe a lower level of intelligence. Neonatal hypothyroidism (cretinism) was more common in mountainous inland areas away from sea salt sources of iodine. It is very rare in the modern world because of the required screening of all infants at birth (blood tests measure levels of thyroid-stimulating hormone and thyroxine). Screening testing of mothers during pregnancy and of infants shortly after birth with dried blood spot (DBS) technology allows treatment and lifetime monitoring before the serious signs of thyroxine deficiency occur. This disorder and others (e.g., phenylketonuria [PKU]) are health screenings' modern success stories. Neonatal hypothyroidism has virtually disappeared in the developed world as a result of the screening of babies (target population) followed by appropriate treatment for affected individuals. However, the storage and research use of DBS technology raises significant controversy over lack of parental knowledge and consent for research activities; in some states privacy laws may inhibit retention of DBS samples without explicit parental knowledge (Botkin et al., 2013).

Very recently biotechnology companies have developed tests that aim to screen an individual's DNA for genes associated with diseases or population

subgroups (Nickolich et al., 2016). DNA testing examines a person's genetic code to provide information about genealogy or ancestry that may be helpful in assessing a person's risk of disease. Personalized DNA testing kits are available to help consumers discover their risks of developing disorders (such as Alzheimer disease, diabetes, and breast cancer). An over-the-counter home test for human immunodeficiency virus (HIV) was approved by the Food and Drug Administration and was marketed to consumers in 2012. The availability of screening options that may be novel, but unproven, raises new questions about media information provided to the public, the politics involved (Lin & Gostin, 2016), and the reliability and validity of screening methods and associated necessary counseling.

- Why has the newborn period been identified as an important time to require screening tests?
- Each government regulates a list of mandated screening for newborns. Do you know what your government/state/ministry of health requires?
- The availability and feasibility of screening tests is constantly changing. How are new screening tests evaluated and added to the mandated requirements?
- What characteristics of screening tests have to be considered for neonates? What characteristics of screening tests have to be considered for individuals of any age?
- How is the margin of error further defined for screening tests/instruments?
- What aspects of screening program development should nurses participate in? Assessment, data analysis, implementation, evaluation of health outcomes?

Evidence-based preventive services are effective in reducing death and disability, and are cost-effective or even cost-saving. Preventive

services consist of screening tests, counseling, immunizations or medications used to prevent disease, detect health problems early, or provide people with the information they need to make good decisions about their health. While preventive services are traditionally delivered in clinical settings, some can be delivered within communities, work sites, schools, residential treatment centers, or homes (National Prevention Council, 2011, p. 18).

Clinical and community preventive services are vital to health promotion and disease prevention. Identified as such, they have become one of the four strategic directions of the National Prevention Strategy (safe community environments, elimination of health disparities, clinical and preventive services, empowered people). Most adults are not up-to-date on the core set of clinical preventive services recommended at various ages, and the proportion of older adults who are current with their screening or are unwilling to be screened diminishes as more screening strategies are added (Bynum et al., 2012; Davis et al., 2012). Screening is an important component of clinical preventive services because it is a valuable tool for health care professionals to identify chronic conditions and risk factors before the condition becomes costly both in financial terms and for quality of life. This is particularly important as the health care paradigm shifts from medical and volume-based to a health-promotion and value-based model of care. Although health education about screening is categorized as part of the rubric of primary prevention, the actual process of screening is part of **secondary prevention.**

The primary goal of screening is to detect risk factors and a condition early, to prevent or treat it, and to deter its progression. An important assumption underlying the use of screening is that detection early in the asymptomatic period allows treatment at a time when the eventual course of the disease can be altered significantly. Similarly, identifying risk factors assists in identifying the populations needing screening and focuses attention on needed behavior change before disease develops. Screening strategies are based on the principle that the selected disease is preceded by a period of **asymptomatic pathogenesis** or latency (disease development before

symptoms first appear) when risk factors predisposing a person to the disease are building toward full manifestation of the disease (Figure 9-1). Screening takes advantage of the prepathogenic state and the early pathogenic state—identifying risks relating to disease in the earliest and most treatable stages.

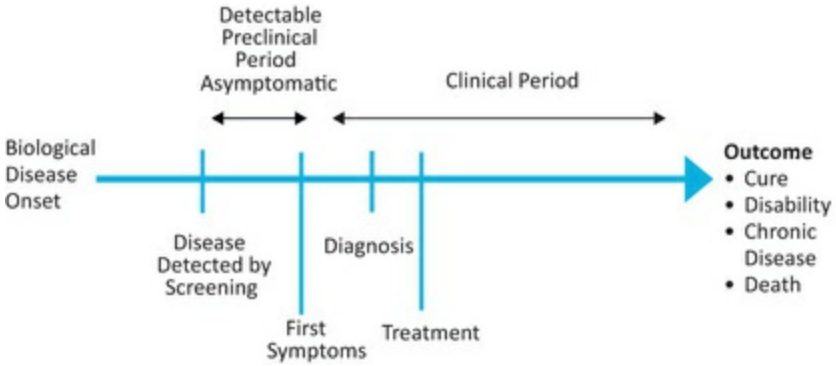

FIGURE 9-1 Screening periods.

Screening strategies are essential to the core of the health-promotion metaphor—the upstream/downstream narrative. When health care providers are so preoccupied with managing the acute care (ill/dying) of the drowning downstream, they have little time to focus on why individuals become ill and fall into the river upstream. Screening tests focus attention on going upstream to the source to better identify valid determinants of health status. Identification of valid health status measures involves accurate screening tests.

Administration of screening tests, some of which might be fairly simple and relatively inexpensive when compared with the burden of disease, provides value in improved quality of care and decreased health care costs. Screening is not generally a diagnostic measure, nor is it curative. It is a preliminary step to identify (upstream) individuals who need more diagnostic workup to prevent further development of the condition or disease and to ameliorate adverse disease outcomes. More importantly, it is a step toward empowering individuals to make more informed choices about their health and health behaviors. A second, but equally important, objective of screening is to reduce the costs of managing the disease by avoiding more intensive

interventions required in later disease stages. A cost-conscious approach to health care mandates that health care professionals, at all levels, acquire a basic understanding of the screening process and its application. Unfortunately, upstream screening and the application of screening processes involves complicated decision-making, and is entangled with social policy, communication and media information, and personal choice.

Advantages and Disadvantages of Screening

Advantages

Some screenings are very simple and performed at home (blood pressure, heart rate, weight, even currently oxygen saturation), and nurses are involved in promoting their use and educating people about their use. This chapter, however, will focus more on the efficacy and efficiency of clinical, procedural, and laboratory-based tests. Screening tests offer several advantages. Although some screening procedures are simple and relatively inexpensive, others are expensive and may not be cost-effective. The simplicity of some screening procedures decreases the time and cost of the health care personnel involved, especially when compared with the cost of treating the disease after symptoms appear, and enables less skilled technicians to administer the test.

A second advantage is the ability to apply the screening process to both individuals and larger populations. In an **individual screening** program, one person is tested by a health professional who has selected the individual as high risk (such as prior hypertension). The practitioner can make this decision independently; the health care agency can define a specific policy; or legislative bodies can require the screening by law as in the case of newborn hypothyroidism and PKU, or lead-screening programs in children.

PKU is a rare genetic disorder that causes the level of an amino acid, phenylalanine, to build up because of a metabolizing enzyme defect. Children who are identified as having PKU can be placed on a phenylalanine-restricted diet and medication to avoid the worst complications of PKU-related disease (neurological problems, delayed development, and intellectual disability/mental retardation). Lead screening for children is an essential component of the well-child visit. Children younger than 6 years are at greatest risk, and once exposure has occurred, it is difficult to reverse toxic effects (Ness, 2013). A

pediatrician in Flint, Michigan, who was reviewing positive lead screening test results in children alerted public health authorities and the state to the existence of high lead levels in the city water. As electronic health records become more digital, an electronic flag during well care visits ideally alerts the provider when the care recipient needs recommended screening.

Group or mass screening occurs when a target population is selected on the basis of an increased incidence of a condition or a recognized element of high risk within an identified group. For example, the target population may be invited to a central location on a designated day to be tested for the selected disorders (elevated levels of lipids and cholesterol, hypertension, osteoporosis, elevated blood glucose level).

A third advantage is the ability to provide one-test disease-specific screening or multiple test screenings. A **one-test disease-specific screening** is the administration of a single test that searches for a characteristic that indicates a high risk of developing a disorder. An example of this would be blood pressure screening to evaluate hypertension (Yoon et al., 2015). **Multiple test screening** is the administration of two or more tests to detect more than one disease. In some cases, one sample can be used to evaluate an individual for several conditions, saving time and money and making the process efficient and economical. For example, a blood sample can be assessed for a number of components, including glucose and cholesterol levels. The combination of the relatively low-cost screening test and flexibility makes screenings adaptable to all levels within the health care delivery system. Other multiple test screenings of importance are for substance abuse, mental health disorders and depression, and sexually transmitted infections (STIs).

A final advantage of screening is that it creates an opportunity for providing health education (see Chapter 10) to a group of individuals who may not otherwise receive it. In some situations, it is possible to establish a clinical relationship during the screening process that leads to preventive visits and includes educating people about healthy lifestyles, risk reduction, developmental needs, activities of daily

living, and preventive self-care. Many of today's chronic illnesses are a result of individual health behaviors. Awareness is the first step in prevention. If better awareness is combined with health-education and health-promotion tools, individuals have a better opportunity to manage their own risks. Taking advantage of a potential health-promotion teachable moment should never be overlooked.

The commonly recommended 6-month dental screening is an example. Although the individual is at the dentist's office to be screened for cavities and to have teeth cleaned to avoid gum disease, the hygienist provides education and reminders on the correct way and the necessity to brush and floss teeth correctly, and a check is provided for oral cancer. Another example is the in the recommended counseling for tobacco cessation—ask, advise, assess, assist, arrange (Agency for Healthcare Research and Quality, 2014b). It is not enough to simply screen an individual with the question, "Do you use tobacco?" Readiness to quit should also be determined and combined with cessation treatment assistance (Centers for Disease Control and Prevention [CDC], 2014). Nurses who are familiar with community resources can then refer individuals to smoking cessation programs that fit with the person's preferences and values (Broder, 2013).

Disadvantages

The primary disadvantages of screening stem largely from uncertainties in scientific evidence, which sets normal testing ranges and therefore also ranges of error for screening tests. When effectiveness depends on the screening program's ability to distinguish those who probably have the disease from those who do not, any margin of error can result in serious consequences. Some individuals who do not have the condition will be referred for further tests, and some who do have the disease will not get needed referrals. Those incorrectly referred (false positive) suffer needless anxiety and unnecessary medical interventions, some of which can be harmful, while awaiting more definitive diagnosis (e.g., high levels of prostate-specific antigen [PSA]). False positive osteoporosis screening results can lead to unnecessary bone building medication treatment that may

have adverse effects. Some noninvasive prenatal strategies test for very rare disorders, so the predictive value may be questioned (Nickolich et al., 2016; Vora & O'Brien, 2014). Mammography screening for breast microcalcifications identifies a significant number of women (who may be false positives) who later undergo medically invasive breast biopsies. Women with false positive results bear the burden of the follow-up visits, lost time, inconvenience, and the cost for follow-up interventions to determine whether the disease is actually present.

The effects on those whose diseases have been overlooked (false negative) are even more important. For example, in maternal serum sampling for fetal DNA (cell-free DNA testing), false negative reports have occurred with twin pregnancies and cell mosaicism (possession of normal and abnormal cells) in either the baby or the placenta (Nickolich et al., 2016). These individuals have a false assurance of health that will be shattered eventually when the illness becomes obvious; they lose the opportunity to receive earlier treatment that could prevent irreversible damage. The difficulty of balancing the benefits to some against the burdens to others may be an ethical issue underlying many screening programs. The significance of this disadvantage can vary; therefore, it should be assessed for each screening program, disease, and population.

Selection of a Screened Disease

The selection of a screened disease goes beyond examination of any disease alone. The selection process must also encompass less tangible factors, such as the emotional impact (HIV infection) and the financial impact (osteoporosis) (Nayak et al., 2011) of the disease's detection on the screened population. Even after data have been gathered and the critical issues have been reviewed, the final decision of whether to screen individuals must often be reached with incomplete evidence or with answers that raise ethical issues, on an epidemiological and a personal level.

The potential uncertainties confounding the decision to screen individuals emphasize the need to conduct an analysis of available material to obtain a decision that is as objective and scientific as possible. Answers to the following questions may provide a basis for designating a disease as screenable or not screenable:

- Does the significance of the disorder warrant its consideration as a community problem?
- Can the disease be detected by screening?
- Should screening for the disease be done?
- What are the health benefits? For example, can it be treated?
- What are the tangible and intangible costs?

As simplistic as these questions may appear, the answers or lack of answers, in addition to individual preferences, may expose complex issues that determine whether a well-informed decision can be made on screening.

Significance of the Disease for Screening

According to the CDC, **epidemiology** is the "method used to find the causes of health outcomes and diseases in populations. In epidemiology, the patient is the community and individuals are viewed collectively. By definition, epidemiology is the study

(scientific, systematic, and data driven) of the distribution (frequency, pattern) and determinants (causes, risk factors) of health-related states and events (not just diseases) in specified populations (neighborhood, school, city, state, country, global)" (CDC, 2015).

Health information on both morbidity and mortality may be used to identify the most important diseases affecting populations. The term **morbidity** refers to a diseased state or disability from any cause; however, the view of morbidity can be broader, including a range or degree of the illness that affects the person. **Mortality** statistics (deaths) in a given population can be easier to use as end outcome indices as long as statistical collection measures are accurate.

The **significance** of a disease refers to the level of priority assigned to the disease as a public health concern. Although the opinions of political and public interest groups may influence this evaluation, significance is generally determined by incidence and prevalence, and by the quantity (severity) and quality of life affected by the disorder (CDC, 2012). The media may also have a role in defining a public health problem which should be screened for, or addressed, as the media provides a place for compelling storytelling about the impact of disease and potential screening (Dorfman & Krasnow, 2014). The ability of the Zika virus to infect the fetus and cause neurological problems and microcephaly is a graphic example of the media telling the story of mothers and babies infected and the spread of this virus worldwide.

Key factors in assessing the need for screening criteria are quantifying measures of disease frequency. The two measures most used in epidemiology are incidence and prevalence (CDC, 2012; Lundy & Janes, 2014). **Incidence** indicates the rate of a new population problem and estimates the risk of an individual developing a disease or condition during a specific period or over a lifetime. **Prevalence** is the proportion of a given population with the disease or condition at any one point in time. It provides the best estimate of whether a person is likely to become ill during a specific period. In short, incidence is new cases, and prevalence is all cases within a set period. Chronic conditions are usually measured by their

prevalence (generally existing), whereas acute conditions are assessed by their incidence (rate of new occurrences). Both are used in assessing the need for community services and screenings, and help develop the criteria for evidence-based practice screening guidelines that include the age at which screening should be performed, the frequency and manner of screening, and the person who should perform the screening. The greater the physical and psychological harm experienced by the population, the greater is the urgency to designate the condition/disease as a priority health problem. A first step in assessing screening feasibility is evaluation of disease significance to decide if the disorder warrants the time, effort, and financial resources that must be allocated. For example, there has been a significant decline in the incidence of late-stage colorectal cancer in the United States since 1987, and this is attributed to increased rates of screening (Yang et al., 2014).

Estimating the **quality of life** affected by a disease presents problems but is also a necessary step. The perception of quality of life is subjective, and individual evaluations may differ. For example, not all people equally perceive the disability resulting from a disease; some may make adjustments and cope, whereas others do not. Those who do not may be more likely to say that the quality of their lives is significantly lower than that of other people.

Two epidemiological measures are used to estimate quality of life. A **quality-adjusted life year** (QALY) is a measurement of quality of life. It is defined as perfect health minus the disability-adjusted life year (DALY). The QALY assumes that 1 year of excellent health is 1 QALY (1 year of life times 1 utility value equals 1 QALY). It also assumes that 1 year spent in a less perfect state of health or with disease (or comorbidities) is worth less. A determination of the QALY value involves multiplication of the utility value associated with a state of health by the number of years lived in that state of health. Following this thinking, half a year lived in excellent health is 0.5 QALY (0.5 year of life times 1 utility value), which is the same as one full year of life lived in a disease state (immobile, fractured hip assuming half utility value) (1 year times 0.5 utility value).

A second measure, the **disability-adjusted life year** (DALY), refers to a year spent in less than healthy life. It is a measure of the burden of disease, and measures the gap between the current health status and excellent health status. It also accounts for life lost and life quality diminished through disability. The QALY and DALY measures may both be used depending on whether the outcome of the screening measure is intended to maximize health or minimize disability (Costello, 2014; Airoldi & Morton, 2009).

There is currently greater focus on quantifying measurements of health outcomes so as to weigh the costs of screening, treatment, and effects on populations. The QALY incorporates morbidity and mortality in a single arithmetic measure. It allows computation, estimation, and comparisons of screening decisions. However, the estimation of formulas association with utility and disability is difficult. QALYs assist in analyzing the gap between strict treatment decisions and their economic costs, informing public health decision-making (Costello, 2014).

By contrast, measures of the **quantity of life** affected by the disease are more readily obtainable. In addition to prevalence and incidence rates, disease-specific mortality rates present different aspects of the disease for analysis. Disease-specific mortality may be linked to the severity of an incident occurring or the longtime health burden cost associated with management of the disease. There is some evidence that mandatory screening of athletes reduces the incidence of sudden cardiac death in athletes who are supposedly young and fit; the cost of comprehensive cardiac screening is high and controversial (Anderson et al., 2014; Shephard, 2011); a death in a young athletically fit person is a very untoward, severe event. With other diseases, the prevalence of the disorder may not be high, but the problem requires disproportionate amounts spent on maintenance or management after the condition is fully expressed. For PKU, a case undetected at birth means a lifetime of suboptimal development and neurological disease management.

Detection

With the relative significance of the disease established, the next step is to determine if health professionals can screen individuals for the disease. Are there well-documented diagnostic criteria for the disorder? Is there a valid and reliable screening instrument? Are sufficient community resources and treatment modalities available to support a screening program?

Diagnostic Criteria

Detection of a disease requires knowledge of the characteristics that indicate its presence or, as in screening, its early pathogenic, asymptomatic state, and is often based on risk factors such as heredity, age, sex, and family history. For example, screening tests may be recommended for men or women (US Department of Health and Human Services, Office on Women's Health, 2012, 2013; Womenshealth.gov, 2013). Selected disease diagnostic criteria should be well documented and defined and not merely accepted as commonly used indicators. The impact of uncertainty in detecting disease is amplified when the application of the screening design is considered. Some diseases, such as sickle cell anemia or PKU, are defined by the presence or absence of a single, isolated gene or enzyme. Other conditions, such as high blood glucose levels (diabetes), are measured according to numerical values for which a normal range has been set. Although there may be some disagreements over normal parameters, diabetes is a serious disease, and early treatment has been shown to decrease the incidence of morbidity and death attributable to vascular diseases and stroke.

Screening Measures

The next step is to determine if methods exist to detect the disease during an early stage. If screening measures are available, an analysis should determine if any of them fulfill the requirements for the screening process: available, easy to administer, safe with minimal discomfort, cost-effective, and accurate. Ultimately the decision to use a screening test will depend on how well the measure can distinguish

those individuals who probably do not have and will not develop the condition from those who are likely to develop the condition. The variables that aid in a screening instrument's evaluation include reliability, validity, and reproducibility, which are a measure of the accuracy of the instrument.

Reliability is an assessment of the reproducibility of the test's results when different individuals with the same level of skill perform the test during different periods and under different conditions. The instrument or measure should yield consistent or stable results over time. If the same result emerges when two individuals perform the test, **interobserver reliability** is shown. If the same individual is able to reproduce the results several times, **intraobserver reliability** is demonstrated.

From this information, health professionals can determine the amount of training required for health care professionals, technicians, or personnel who administer the test. For example, if interobserver reliability is low, additional training might be required to work toward a more consistent method of screening test delivery. This is frequently necessary in blood pressure cuff hypertension screening (Ringrose et al., 2015) or in weight measurements, where the scale may not function properly. If intraobserver reliability is low, the health professional might surmise that the instrument, and not the individual, is at fault. Some screening measures are of necessity more qualitative, and intraobserver reliability may be very important in the case of substance abuse or mental health/depression screening. Finally, for a screening test to be valid, which is the next requirement, it must first be reliable, but reliability is only a necessary condition and is not entirely sufficient for validity.

Validity reflects the accuracy or truthfulness of the test or instrument itself. In a controlled setting, one evaluates validity by testing the instrument on a group of individuals who have positive or negative results. A valid test correctly distinguishes individuals who have preclinical disease from those without preclinical disease. The ideal result is to have the instrument identify 100% of the diseased individuals (positive reactions) and 100% of the nondiseased

individuals (negative reactions).

There are also ranges of measurement for disease reliability and validity. Perfectly accurate categorization of validity rarely occurs in practice; therefore the measure of validity has been divided into two components that quantify the margin of error in screening instruments. **Sensitivity** measures the first component. This refers to the proportion of people with a condition who correctly test positive when screened. If a test has good sensitivity, the number of individuals with the disease who are missed through inaccurate categorization as false negatives will decrease. Conversely, a test with poor sensitivity will overlook individuals with the condition, and there will be a large number of **false negative test results:** individuals actually have the condition but were told they are disease-free or tested negative for the disease.

Specificity is the second component. Specificity measures the test's ability to recognize negative reactions or individuals in which disease is absent. A test with excellent specificity will rarely produce a positive result if the disease is not present. A test with poor specificity could result in **false positive test results.** Individuals with false positive test results are told that they have a disease or condition when in actuality they do not. Specific epidemiological formulas are used to measure both sensitivity and specificity.

In a perfect world, tests would be highly sensitive and highly specific; however, that is usually not the case, and some balance is reached between the two concepts. For some tests, there may also be an indeterminate zone in which the individual does not test strictly negative or positive. In these tests, the numerical cutoff may be subject to interpretation or a more arbitrary decision. A cutoff decision may be made so that the screening instrument is less likely to miss actual cases of disease at the cost of erroneously identifying cases of disease (false positives) that will need more diagnostic work, which may be expensive and invasive.

Consider the issues that a public health nurse faces when using a newly developed screening test with low specificity and moderate sensitivity. Low specificity means few true negative test results and

more false positive test results. This is the current situation with mammography screening. The nurse and other health professionals (also health advocacy groups, such as those involved in breast cancer awareness) must then consider the cost, inconvenience, and psychological stress experienced by the people with false positive results during the period after their incorrect screening test, the unnecessary additional referrals, and the ability of the existing follow-up services to meet these needs. With only moderate sensitivity, a number of false negative results could occur, which may ignore individuals who could benefit from treatment. Medical, economic, political, and ethical issues are involved; that is, should a screening program be implemented when it is known that the tests may involve avoidable harms such as additional biopsies and excessive treatment. The use of mammography screening became a special case for inclusion under Affordable Care Act coverage as this legislation requires coverage for preventive services having a certainty of moderate or substantial benefit, and mammography science testing to date cannot meet that level of accuracy (Lin & Gostin, 2016).

A broader issue concerns large health fair screening programs; for example, where a targeted population such as older adults is sought for a mass screening. The **efficiency** and **efficacy** of such programs must be analyzed. The following are examples of questions that address efficiency and efficacy: Is the targeted population prepared in an appropriate way before engaging in the screening tests? Are the health care practitioners who are administering the test educated (and certified) according to the standard protocols of test administration? Are follow-up measures and appropriate referral access instituted in the program? There are times when an older adult lacks the cognitive ability or finances to follow-up on positive screening results. Patients and health care providers may overestimate the benefits and underestimate the harm of screening and associated treatment (Hoffmann & Del Mar, 2015). Answers to these questions challenge health care providers in the development, implementation, and follow-up processes identified so that screening efficiency and efficacy is enhanced.

Very recently, a number of for-profit genomic and biotechnology companies have marketed genetic tests (Box 9-1: Genomics) to identify genes and ancestry associated with risk factors and diseases. A number are available on the Internet. One of the most widely known, *23andme* (http://www.23andme.com), reports that its DNA analysis can provide information on about 100 health disorders and traits, including carrier risk, drug response, and disease risk (e.g., Parkinson disease, cholesterol levels, presence of diabetes). Noninvasive prenatal tests are currently marketed to identify neonatal chromosomal abnormalities, including Down syndrome, very early in gestation with a simple blood test (Nickolich et al., 2016); these tests are less invasive than amniocentesis, but positive test results require confirmation by amniocentesis. These tests are becoming common and dramatically less expensive.

Box 9-1

Genomics

Detection of Maternal Malignancies via Prenatal Testing for Fetal Chromosome Abnormalities

Prenatal screening on blood samples is becoming the norm and is reducing amniocentesis testing. This less invasive blood test determines whether the fetus has a chromosomal abnormality (Down syndrome—chromosome 21, or other chromosomes—13, 18, X, and Y) by testing free DNA. If the finding is abnormal, amniocentesis is used to confirm the original result. In this study (Bianchi et al., 2015) of 125,426 blood samples, 3% were found to be abnormal.

What is interesting about this study is that this prenatal screening may identify not only problems in the fetus but also problems in the mother's cells' arrangement indicative of cancer. From the set of 3757 abnormal fetal results, 10 cases of maternal cancer were found.

The uses of genomic testing are just beginning to be realized and may lead in directions unexpected from the original purpose of the

screening.

From Bianchi, D. W., Chudova, D., Sehnert, A. J., Bhatt, S., Murray, K., Prosen, T. L., et al. (2015). Noninvasive prenatal testing and incidental detection of occult maternal malignancies. *JAMA, 314*(2), 162–169.

Green and Farahany (2014) reported that the Food and Drug Administration (FDA) may be overcautious in its oversight of consumer genetic testing/genomics as the FDA is requiring stricter disclosure of information to consumers. Consumer-available tests can involve issues of standardization, cost, and privacy, and failure to make reports fully explainable or understandable. Comprehensive research on screening tests significantly influences the efficacy of the entire process. Data on the reliability and validity of individual tests and screening programs in general provides valuable information to evaluate, anticipate, and ideally control these influences, enabling the program to work effectively toward its established goal and positive health care outcomes.

Primary Care and Community Screening Resources

Screening is often done in an outpatient primary care setting. As funding for traditional public health nursing roles is declining, the responsibility for screening often falls to nurses in other basic and advanced practice roles. Implementing a screening program depends on availability of appropriate **community resources,** such as funds, health care workers, and follow-up services, including access, referrals, treatment sources, and administrative personnel. Nurses can provide structure and design for screening programs as seamless organization of a program is essential to success. Knowledge of a disease's characteristics and an effective screening instrument are useless without financial and organized human support to use them. Many screening programs are of necessity complex, requiring intense efforts in the area of partner development.

A **lead agency** or group may be identified to oversee the

development of the community health program. The origins of the lead agency range from a community service organization to local public health departments responding to regulations or a mandate at the state or federal level. Regardless of its origin, the agency must perform a self-evaluation to compare its level of expertise with what is required to supervise the process of the screening effort. Early identification of the lead agency, along with potential partnerships, allows the effective use of talents and the division of labor.

Some screening programs may involve intricate legal issues; for example, states have policies about HIV testing and privacy and identification of individuals. HIV screening and testing is highly recommended in high-risk individuals—those who have injected steroids or drugs, those who have unprotected sex (especially men who have sex with men), and those who have other STIs or comorbidities (e.g., hepatitis C). Consumer-controlled home screening kits may protect individual identities (CDC, 2011). In 2012, the FDA (2012) approved the first over-the-counter HIV test. This test, OraQuick (http://www.oraquick.com), requires a fluid specimen from the mouth at the upper and lower gums and gives preliminary results in 20 minutes.

For the lead agency to develop and oversee the development of any community health program, such as the delivery of a screening program, partnerships and coalitions are essential. The agency must contact and organize necessary stakeholders. **Stakeholders** are individuals or groups who have a legitimate interest in the topic. Examples of stakeholders include key community individuals; hospitals; health and social service agencies, such as primary health care centers; and community organizations, including houses of worship, community centers, schools, transportation agencies, and volunteer organizations. **Key community individuals** are those people who are considered leaders within the community. The primary rule is to never assume that what is appropriate and effective for one community will be appropriate and effective for another.

Stakeholders and partners along with nurses perform the **community assessment** together. A community assessment is a

systematic method of data collection that provides a detailed account, first identifying need and subsequently determining the type, quantity, and quality of resources. Review of demographic, vital statistics, and morbidity and mortality data may identify the assessed need. Resources might come from an eclectic variety of support sources, including government entities such as public health departments, social services, and even safety and transportation in the case of car seat safety screenings. Schools, private businesses, churches, and places of social gatherings might provide resource support, either in screening support or in the actual administration of the screening.

After the assessment has been completed, the data analysis will reveal the **target community** or high-risk population, the available health care resources, and the health needs of the high-risk population. The identified partners collaborate, review, and analyze the data, leading to the development of health-improvement strategies (in this case a screening program), with methods of implementation to move the target population smoothly through the screening process. Finally, monitoring and evaluating outcomes is essential to determine the effectiveness of the program and the achievement of stated goals. Evaluation includes monitoring of the entire process, including the successful workings of the partnership. Figure 9-2 presents a model of collaborative partnership: community health program development. Population health nursing is an important component of the partnership.

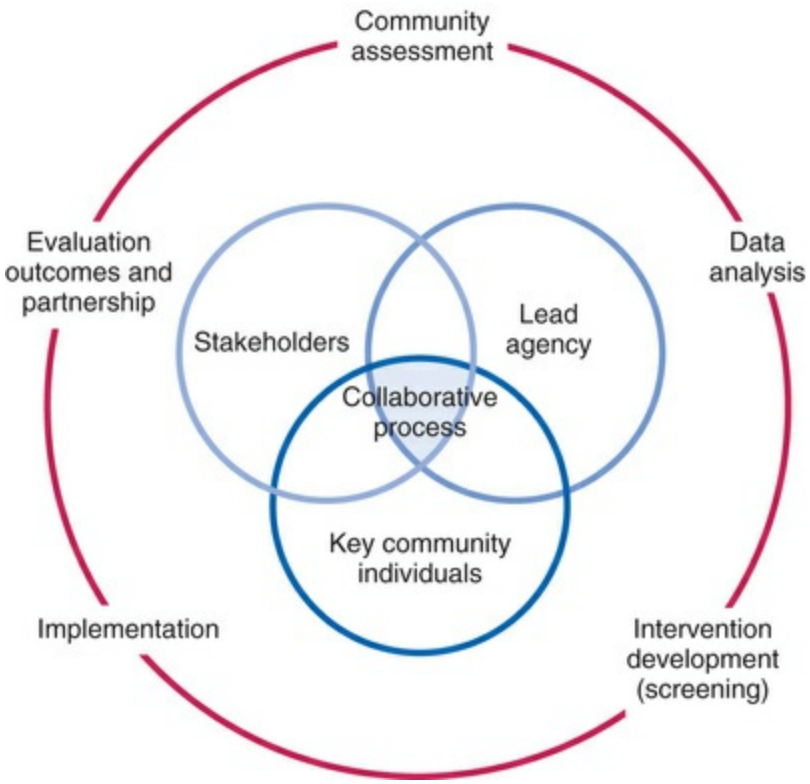

FIGURE 9-2 Collaborative partnership: community health program development.

The constraints affecting the operation of a screening program include financial concerns, political issues, cultural constraints, follow-up and referral services, and accessible treatment facilities. All partners are aware that responses from the target community are affected partly by their experience with other screening programs, such as the means used to inform them, the accessibility of the location, the availability of transportation, the convenience of the program's hours, and the cultural sensitivity of the delivery and design of the program. A public health nursing approach identifies the necessary community resources and defines how these resources interact and may be mobilized to achieve maximal benefits and positive outcomes. Financial support of a screening program is a constraint that can influence all points in the system. Although some programs are delivered entirely on a voluntary basis, organizers of others must submit grant proposals to local, state, or federal departments when consideration of medical and economic ethics is

involved. Planners must look beyond the screening day and investigate financial resources for follow-up care and treatment.

In addition to financial accessibility, follow-up services need to be accessible in terms of convenient locations and open hours. For example, an evening clinic may reach those who are reluctant or financially unable to miss work. Nurse practitioner clinics facilitate access to preventive health services at convenient times for various population groups. An efficient referral system links the follow-up resources to the screening program, providing continuity of care. A method must be devised to encourage the participant to take positive action on the referral. Public health nurses will facilitate this process with a variety of communication techniques, such as e-mails, telephone or in-person counseling, mailings, and home visits.

Another example is that a college of health sciences organizes a health fair which includes screening. This also creates opportunities for **interprofessional education** and practice (Uden-Holman et al., 2015). Nursing students and medical students manage physical assessments and laboratory screenings. Pharmacists screen individuals for medical use of inappropriate or contraindicated medications. Social workers may assess individuals for mental health issues. There is a plan for continuation of care if disease issues and risks are identified; for example, individuals needing immediate referrals for hypertension control. In this instance the college may agree to assist in referrals to providers who will donate time to assist in this effort.

Should Screening for the Disease Be Done?

After it has been determined that the disease is significant and can be screened for, establishing whether health professionals should do so is the final step. Screening for a particular disorder and ultimately treating those with the early-identified disorder improve the chances of a favorable outcome in comparison with those whose disorder is not found until signs and symptoms become evident. Therefore several questions must be considered. If a test accurately identifies a condition in the early stages, is there any benefit to the individual?

Are there effective treatment modalities for the condition? The **US Preventive Services Task Force** (USPSTF) may recommend against routine screening (USPSTF, 2016a). In 2012, the USPSTF recommended against PSA screening for prostate cancer. PSA screening was rated as grade D (not recommended) because the balance of harms from early treatment (urinary incontinence, bowel control, erectile dysfunction) outweighed the benefits of early diagnosis. As noted before, recommendations for mammography screening have changed several times within the last decade because of high rates of false positive test results, overdiagnosis, too many normal/benign biopsy specimens, and overtreatment (Kidd & Colbert, 2015; Lin & Gostin, 2016; Thompson et al., 2015). A woman with microcalcifications found on mammography may have to undergo an open or core biopsy to determine if cancer cells are truly present; this may involve several days' absence from work or child care.

It is necessary for the health care provider to remain aware of changes in screening guidelines. Screening is based on the disease's asymptomatic period; therefore adequate information must exist concerning the optimal time for screening, specific intervention during this time, and knowledge regarding the effect of early detection and treatment on the prognosis. Without this knowledge, health care professionals are unable to explain how the outcomes of those with early detected disease differ from those with undetected disease, and they cannot support the health benefits derived from the screening program.

Follow-up is critical to determine if the intervention strategies prescribed are in fact happening. Should screening be done if there is no follow-up in terms of medical or social services? A prescribed follow-up regimen may be very broad and include a wide variety of intervention strategies, such as diet, exercise, and drug therapy. Follow-up services may include an evaluation and review of the literature that discusses evidence-based practice pertaining to a particular drug, as well as the identification of intervention characteristics that impair follow-up, such as cost, inconvenience, or side effects. Consideration must also be given to those factors that

enhance follow-up. For example, nurses can provide ongoing counseling and education about a medication and assist individuals in lifestyle transformations that include health-promoting behaviors.

The safety of a potential intervention is a concern when the widespread application of further medical interventions or invasive diagnostic tests after a screening program is considered. Risks or harmful side effects can be costly in terms of human health and the increased medical care required to correct **iatrogenic** or interventional effects (e.g., additional surgical procedures or emotional distress). As an example, Jordana, who is aged 54 years and has a low risk of breast cancer, attends a community clinic and wants more information about the optimal interval between breast cancer screenings. She heard that there are disagreements between US government studies (USPSTF), the American Cancer Society, and other sources of reasonable medical advice. The nurse, using an evidence-based practice model, helps Jordana to find or review the most recent and best sources of information that would answer her question (Mandelblatt et al., 2016). In addition to the scientific literature, the nurse locates consumer information for Jordana. In this case the nurse would assist women to make informed health choices about screening tests.

The bottom line is that to be effective, a high-quality, cost-effective, research/evidence-based screening tool or technique is needed that identifies a real or potential "problem." Screening must provide real and workable "solutions," in which the tangible and intangible costs of the screening are less than the risk of the disease and result in measurable health benefits.

Ethical Considerations

Improving health is considered a just and moral act integral to values endorsed throughout the care delivery system. Screening activities are separate from interventions offered for established disease (e.g., myocardial infarction). Rather than treating those who have established disease, a screening program invites seemingly well individuals to be tested to determine their disease risk and the need for follow-up. This request for voluntary participation implies an expectation of a health benefit, although at this stage nothing is said about what it will be, the cost, or what the participant must do to obtain it. Screening programs need to clarify expectations and inform participants as contingent issues occur. Screening participants need to know whether the ultimate benefit is preventive, ameliorative, or curative and what responsibility they assume to secure this outcome.

Borderline Cases and Cutoff Points

A screening program measurement is often based on a numerical value, so a question often arises about the use of cutoff points for the screening instrument and borderline cases. The goal of a screening program, identifying an individual as having high risk or not having high risk, depends on this numerical value. When the clinical parameters are not clear, a cutoff point is used. Above this point, the person is considered to be disease positive; below this point, the individual is disease negative. Consequently, readjusting the cutoff point can become a highly controversial issue, as the cutoff point controls the percentage of positive and negative results. If the disease were potentially life threatening, an increase in false positive results (lower cutoff point) would be preferred to missing individuals who may have the disease. In addition, if a disease is relatively benign in terms of potential stigmatization, anxiety, and problems with treatment, lowering the cutoff point could again be safe and ethical.

Examples of problems related to identifying cutoff points and

borderline cases are common in community nursing practice. Hypertension is a common disease in which a variance of 5 to 10 mmHg can make the difference in identifying a person as having high risk of hypertension. Lipid and cholesterol level cutoffs and ratios are always subject to further examination. Osteoporosis standards for men are debated (USPSTF, 2015). Recommendations change as new evidence emerges. Sophisticated approaches may discriminate between borderline cases that should be referred and ones that should not. Nurses can assist in identifying other risk factors associated with hypertension or lipid level evaluation, such as family history, diet, and smoking, as criteria for deciding whether to refer an individual. An updated literature review is imperative before these issues are reviewed in relation to a particular screenable disease.

Economic Costs and Ethics

In the past, the tendency was to disregard the cost of promoting a healthy, disease-free, or disease-controlled status; this results in a philosophical stand that all care should be given to all people at all costs. There is now a fuller recognition of the enormous costs that could be involved with many screening programs. Allocating community funds to a large screening event may result in a lack of funds for other projects. Populations benefiting from a screening test will be balanced by those suffering in terms of decreases in service for other medical or social needs.

The initial operational costs must be considered, including buying or renting screening equipment, floor space, and engaging professionals or technicians to administer the tests and interpret the results. These costs are encountered a second time when individuals are referred for further evaluation. Consumer costs include follow-up visits, treatment, and time and income that are lost. Given the combined operational and consumer costs, several questions are raised. Do the costs result in improved health outcomes? Are the benefits worth the expenditures required? These answers are influenced partly by the values (other than monetary ones) attributed to the benefit. Saving lives in a young population may be judged more

valuable than screening older populations with more chronic illnesses. A strictly economic approach, however, may eliminate the intangible variables and require the use of more objective data for decision-making.

When program designs are reviewed, three main approaches may be used to evaluate the economic resources affected: cost-benefit ratio, cost-effectiveness, and cost-efficiency analyses. The current relevance and use of such concepts require a basic understanding of their role in the selection of a condition for screening. They tend to be separate methods and most frequently are used independently of one another.

Cost-Benefit Ratio

Cost-benefit ratio analysis is performed first, because it allows the comparison of various outcomes in monetary terms. This comparison is necessary in health planning when the initial consideration is dependent on whether the expected health outcome (such as reduction in the incidences of cardiovascular disease, decrease in infant mortality, or reduction of the detection of a visual problem) will be most beneficial to the community at the most reasonable cost. The cost of the screening versus the cost of long-term care management may be weighed. For example, what is the cost-benefit ratio of blood pressure screenings, compared with the medical and financial cost of a stroke caused by undiagnosed hypertension, to the individual, the community, and the health care system? The cost of screening is weighed against other factors, such as the cost and feasibility of vaccination programs, as in the case of screening individuals for human papilloma virus for cervical cancer (Maine et al., 2011). Resources available through the use of electronic data gathering tools, such as the CDC's Chronic Disease Cost Calculator version 2 (CDC, 2013), which estimates state Medicare expenditures for certain diseases, may assist in this analysis.

Cost-Effectiveness

If the reduction of cardiovascular disease is chosen as the desired

outcome, the next step is a **cost-effectiveness analysis**, which determines the optimal use of resources to reach a predetermined, constant end-point or the desired health outcome. The screening benefit remains the same; the best method of getting to the target outcome is the focus of the investigation. For example, for reduction of cardiovascular disease, various methods might be used. These methods include screening individuals for hypertension and cholesterol, performing electrocardiograms on all individuals aged 25 years or older who are admitted to the hospital, screening young athletes for cardiovascular disease, sponsoring an antismoking campaign, or providing nutrition counseling. Implementation of all these options would be ideal, but with limited resources some choices are made.

Cost-Efficiency

The last approach to help bring the economic resources into perspective is **cost-efficiency analysis.** The purpose is to be efficient and budget a limited amount of money toward achieving as much of the desired outcome as possible. The funds are the focus, not the health benefit.

Selection of Screenable Populations

The selection of a screenable population is as important as the selection of a screenable disease and is often based on incidence and prevalence data. The objective is to identify a high-risk group that, when tested, will yield a significant number of diseased individuals. With a well-planned selection approach, the efforts and cost of screening the population are minimized and the health benefit is maximized. The main criterion used to define an appropriate population is the definitive presence of risk factors related to the disorder. Within community settings, nurses can ensure a thorough examination of possible risk factors, including both person-dependent and environment-dependent factors (Box 9-2: Research for Evidence-Based Practice).

Box 9-2

Research for Evidence-Based Practice

Population-Based Research Optimizing Screening Through Personalized Regimens

The National Cancer Institute has developed Population-Based Research Optimizing Screening Through Personalized Regimens (PROSPR) to support research on the community-based screening processes to include experiences and outcomes for breast, colon, and cervical cancer. The overall aim is to develop coordination between the research practices conducted at multiple sites. It reviews recruitment, screening, diagnosis, referral, and treatment rates. It focuses on research translation and implementation, addressing issues such as the controversy regarding breast cancer screening and mammography by studying the comparative effectiveness and outcomes of existing and emerging research. In September 2011 the National Cancer Institute funded seven research centers and one

statistical site as part of this integrated research screening program. Be on the lookout for similar new programs because the Prevention Fund supported by the Affordable Care Act supports the development of other such opportunities to discover and support evidence-based health-promotion and disease-prevention activities.

From National Cancer Institute. (2015). *PROSPR: Population-Based Research Optimizing Screening Through Personalized Regimens*. https://healthcaredelivery.cancer.gov/prospr/.

Person-Dependent Factors

The person's age is important because of age-dependent changes in the levels of risk factors throughout the population. For example, the risk of many cancers increases as a person grows older (Weir et al., 2015). A high priority is placed on screening vulnerable populations, especially women, infants, and children, as the outcomes obtained affect long-range growth and development patterns. As the average life span increases, however, the effects of risk factors in young adults and middle-aged adults are becoming more apparent, making certain prevalent and costly chronic conditions equally important to control. The middle-aged adult population may be screened for hypertension, diabetes, breast cancer, glaucoma, and heart disease; this population is requiring earlier screening as some of these disease conditions are becoming apparent in early adulthood and even teenage years. Older adults may be screened for cognitive decline, although screening for the asymptomatic elderly is controversial because of lack of effective dementia treatment. Routine genetic screening for various biomarkers, such as amyloid amyloid β_2-microglobulin and tau proteins, amyloid plaques, and *APOE-e4* is under investigation (Alzheimer's Association, 2015; Sutphen et al., 2015).

Gender has obvious implications for screening programs. For example, women are tested frequently for two reproductive-related conditions: breast cancer and cervical cancer (Figure 9-3). Screening a population from a particular ethnic or racial group is appropriate as some disorders occur more frequently in certain racial or ethnic groups. For example, black American women are more than 35% more

likely than white women to die of breast cancer, but breast cancer is diagnosed in them 10% less frequently (CDC, 2010; Kidd & Colbert, 2015). Vietnamese American women have the highest rate of cervical cancer among any racial or ethnic group in the United States, and the rate is five times higher than the rates among non-Hispanic white women (CDC, 2010). Nurses can lobby and advocate for specific groups to have more targeted screenings, particularly in communities that have large numbers of ethnic or racial minority women (Box 9-3: Diversity Awareness).

Box 9-3

Diversity Awareness

Eliminating Health Disparities Among Ethnic Groups

The United States has been referred to frequently as a population melting pot. Diversity is acknowledged as a strength of the United States, but it is apparent that disparities exist among the various racial and ethnic groups in the attainment and maintenance of health. The minority populations of the United States include black Americans, Hispanics, Asian/Pacific Islanders, American Indians, and Alaskan Natives. These categories oversimplify the reality of the multicultural nature of assessing health status, screening, and making plans to improve health. These particular racial groupings are not absolute because there are subgroups within each.

These disparities and factors such as access to care need to be taken into consideration when screening programs are being planned. To plan, implement, and evaluate a screening program that targets a specific population, the provider must have an awareness of the target population that includes components such as lifestyle, socioeconomic characteristics, education, heredity, environmental factors, values, religious and cultural beliefs, communication style, and language. Partnering with key individuals and organizations in the community through the entire process is important for any screening program to be successful, as the following scenario illustrates.

Hospital administrators in a town located outside a city in the Northeast are concerned about the health status of a new immigrant population. Recent census data indicate that the number of immigrants from Guatemala has grown. The census data also reveal that this population is primarily young adults, male and female. The officials of the town and the hospital are aware that most of the men are day laborers, many of whom gather each morning in the town

square to be transported to their jobs. The young women are mothers who work in small, privately owned businesses or are hired by local house-cleaning services.

On the basis of these data, the hospital officials decide to plan a health and screening day for this population. The hospital distributes flyers in the community in the primary native language of the target population. The day of the screening arrives, and the number of participants is very low. The hospital officials are very concerned. They had good intentions. They do not know what to do next.

- What critical actions did the hospital officials perform that might be considered positive in the planning of the health and screening day?
- What critical actions did the hospital officials not perform that might have contributed to the poor turnout at the health and screening function?
- What might the hospital officials consider in their planning for the next health and screening day?
- How might they engage the community and the target population in planning the health and screening day?
- What local community agencies and groups might be invited to participate as partners when the health and screening day is being planned and implemented?
- Can you identify any creative ways to bring the health and screening day to the targeted population, making the program more accessible?

Income level has been associated repeatedly with many health disparities. According to a 2010 Gallup poll, chronic conditions are more likely to be diagnosed in low-income Americans than in high-income Americans. The physical health illness disparities were the greatest for depression, high blood pressure, and diabetes, and higher

levels of obesity also place lower-income populations at greater risk (Mendez, 2010). In addition to a greater likelihood of not having adequate health insurance, low-income Americans can least afford necessary preventive care, effective treatment, and health education (Mendez, 2010).

Personal behavioral characteristics related to lifestyle may suggest the need to screen a particular individual or group. When health care practitioners review lifestyle, they are looking at daily habits that affect health and wellness, such as nutrition, fitness level, tobacco use, alcohol and drug use, sexual practices (HIV), stress management, adequate rest, immunizations, periodic examinations, use of seat belts, and other safety factors. Engaging in some of these behaviors while avoiding others is essential for living a healthy life. Therefore screening for personal behavioral characteristics that are considered risky assesses the likelihood of a longer, disease-free life. Once screening recommends elimination of risky behaviors, the development of healthy behaviors via programming and transformation of lifestyles is crucial. Health care providers have a responsibility to educate and empower individuals about the next step in the evaluation of their potential condition once screening has been completed. Those being screened have a responsibility to seek treatment and follow-up services, and ultimately engage in behavioral change toward a healthy lifestyle if the screening is to serve a purpose.

Regional disparities exist and include many of the previously mentioned disparities. These disparities are of great concern, but identifying the cause is complex. Research is being done on interrelationships between the determinants of health, to include biology and genetics, individual behaviors, the social environment, the physical environment, and health services (access and quality). The Centers for Disease Control and Prevention (CDC) **Racial and Ethnic Approaches to Community Health** (REACH) program (http://www.cdc.gov/reach/) addresses the factors and is demonstrating success by empowering residents to "seek better health; help change local health care practices; and mobilize communities to implement evidence-based public health programs

that address their unique social, historical, economic, and cultural circumstances" (CDC, 2010). Appropriate screening is integrated into the REACH program.

Environment-Dependent Factors

The area of environmental health and protection has expanded over the years and is becoming more complex. Environmental health and protection has been defined as the science that is concerned with elements of the environment that influence people's health and well-being. These factors include conditions of the workplace, home, and communities, including chemical, physical, and psychological forces (Allender et al., 2014). Environment-related risk factors relevant to screening designs are associated with an individual's surroundings. Areas that may be considered include overpopulation; indoor and outdoor air pollution; water pollution; safe drinking water; noise pollution; radiation exposure; biological pollutants; hazardous waste management and disposal of garbage; vector and pesticide control; deforestation, wetlands destruction, and desertification; energy depletion; inadequate housing; contaminated food and foods with toxic additives; safety in the home, at the work site, and in the community; and psychological hazards (Allender et al., 2014; Roelofs et al., 2010).

In occupational health, a legitimate population for screening includes those in high-risk work areas, where harmful chemicals, airborne particles, or high-decibel machinery puts the workers at risk of cancer, respiratory conditions, or auditory problems. At the other extreme is the sedentary executive work life, where the lack of exercise is prevalent, placing the worker at risk of obesity and obesity-related conditions such as diabetes. The use of an occupational health nurse to provide individual and mass screening for such problems, in addition to routinely recommended screening, is recognized as integral in promoting better business practices.

National Guidance and Health Care Reform

Healthy People 2020

Many national organizations are guiding and promoting evidence-based care and screening. *Healthy People 2020* has been establishing benchmarks and monitoring progress on goals and objectives to promote health care delivery partnerships, guide individuals toward making empowered health decisions, and assess the efficacy of preventive programs (HealthyPeople.gov, 2015). This newest version of *Healthy People 2020* also includes resources for implementing community programs that support its goals and objectives, including screening. For more specific objectives related to screening, see Box 9-4: *Healthy People 2020*.

Box 9-4

Healthy People 2020

Objectives Related to Screening

- (Developmental) Increase the proportion of persons with a diagnosis of hemoglobinopathies who receive early and continuous screening for complications.
- Increase the proportion of women who receive a cervical cancer screening based on the most recent guidelines.
- Increase the proportion of adults who receive a colorectal cancer screening based on the most recent guidelines.
- Increase the proportion of women who receive a breast cancer screening based on the most recent guidelines.
- Increase the proportion of adults who were counseled about cancer screening consistent with current guidelines.
- Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal

health and wellness in the following areas: handwashing or hand hygiene; oral health; growth and development; sun safety and skin cancer prevention; benefits of rest and sleep; ways to prevent vision and hearing loss; and the importance of health screenings and checkups.

- Reduce the proportion of children who experience developmental delay requiring special education services.
- Increase appropriate newborn blood-spot screening and follow-up testing.
- Increase the number of states including the District of Columbia that verify through linkage with vital records that all newborns are screened shortly after birth for conditions mandated by their state-sponsored screening program.
- (Developmental) Increase the proportion of children with a diagnosed condition identified through newborn screening who have an annual assessment of services needed and received.
- Increase depression screening by primary care providers.
- Increase tobacco screening in office-based ambulatory care settings.
- Increase tobacco screening in hospital ambulatory care settings.
- (Developmental) Increase tobacco screening in substance abuse care settings.
- Increase the proportion of preschool children aged 5 years or younger who receive vision screening.

Recommended Screenings of the US Preventive Services Task Force

More specifically, the USPSTF, part of the **Agency for Healthcare Research and Quality** of the Department of Health and Human Services, identifies recommendations in its *Guide to Clinical Preventive Services* (Agency for Healthcare Research and Quality, 2014a). There are recommendations for adults, children, and adolescents (USPSTF, 2016b). The recommendations evolve as new scientific evidence becomes available, so this chapter will not provide specific details on the recommended screenings. Boxes 9-5 and 9-6 list the USPSTF recommended screening services for adults (USPSTF, 2016b), children, and adolescents.

Box 9-5

Preventive Services for Adults (Examples)

- Abdominal aortic aneurysm screening
- Alcohol misuse screening
- Aspirin for prevention of cardiovascular disease
- BRCA-related cancer in women
- Breast cancer screening
- Colorectal cancer screening
- Depression screening for adults
- Diabetes mellitus screening
- HIV infection screening
- Obesity screening and counseling

- Osteoporosis screening
- Sexually transmitted infection (STI) prevention counseling
- Syphilis infection screening for pregnant women
- Tobacco use Screening

From Agency for Healthcare Research and Quality. (2014a). *Guide to clinical preventive services. Clinical summaries, recommendations for adults, children and adolescents.* http://www.ahrq.gov/professionals/clinicians-providers/guidelines-recommendations/guide/.

Box 9-6

Preventive Services for Children and Adolescents (Examples)

- Alcohol misuse
- Blood lead levels
- Cervical cancer screening
- Child maltreatment
- Developmental dysplasia of hip
- Gonorrhea screening
- Hearing loss
- Height, weight, and body mass index screening
- Hematocrit or hemoglobin screening for children
- HIV infection screening
- High blood pressure screening in children

- Hyperbilirubinemia screening in infants
- Iron-deficiency anemia
- Major depressive disorder screening
- Obesity screening and counseling
- PKU screening
- Sexually transmitted infection (STI) prevention counseling and screening
- Speech and language delay screening
- Vision impairment screening

From Agency for Healthcare Research and Quality. (2014a). *Guide to clinical preventive services. Clinical summaries, recommendations for adults, children and adolescents.* http://www.ahrq.gov/professionals/clinicians-providers/guidelines-recommendations/guide/.

The Affordable Care Act and Prevention Incentives

The passing of the **Affordable Care Act** (ACA) in 2010 catalyzed a public health movement toward prevention and health promotion, with incentives and policies, including the development of the National Prevention Strategy. One result is that preventive services are required to be covered by new health insurance plans or policies, as an incentivized quality program for Medicare recipients. Medicare now also covers annual wellness visits that incorporate a personalized prevention plan according to the recommendations of the USPSTF, based on an individual's age and health status; these visits can be conducted by a variety of practitioners, including nurse practitioners, clinical nurse specialists, and certified nurse midwives (Center for Medicare Advocacy, 2015).

Among other incentives, Medicare has developed a rating guide for

Medicare Advantage programs, incentivizing high-quality health plans with up to a 10% bonus. Many of the criteria that determine the highest ratings are screening and preventive services. This helps seniors identify quality insurance plans that cover preventive services and provide the necessary follow-up.

National Prevention Strategy

In addition to increasing the funded coverage of preventive services and screenings, the ACA also created the National Prevention Council (NPC), comprising "17 heads of departments, agencies, and offices across the Federal government who are committed to promoting prevention and wellness. The Council provides the leadership necessary to engage not only the federal government but a diverse array of stakeholders, from state and local policymakers, to business leaders, to individuals, their families and communities, to champion the policies and programs needed to ensure the health of Americans prospers" (National Prevention Council, 2011, p. 3) (Box 9-7: Innovative Practice).

Box 9-7

Innovative Practice

Informatics, Technology, and Newborn Screening

Health information technology will allow health care to better assess and manage quality health care with the streamlining of efficient and effective information. A number of US governmental sites list information about newborn screening and long-term follow-up. The results of newborn screening may include normal values and out-of-range values. Access to digital medical records allows the sharing of results and follow-up findings between clinicians, testing laboratories, and health delivery providers.

- How does access to newborn electronic screening results benefit the

clinician? How does it benefit the person seeking care? How does it benefit public health?

- Where else do you think health care could benefit from similar abilities?

- What do you think is necessary for this to happen (think about differences in data collection requirements)?

From US National Library of Medicine. (2014). *Newborn screening coding and terminology guide.* http://newbornscreeningcodes.nlm.nih.gov/nb/sc/updates.

The resulting ***National Prevention Strategy*** (NPS) was released in June 2011 and "recognizes that good health comes not just from receiving quality medical care, but also from clean air and water, safe outdoor spaces for physical activity, safe work sites, healthy foods, violence-free environments and healthy homes. Prevention should be woven into all aspects of our lives, including where and how we live, learn, work and play. Everyone—businesses, educators, health care institutions, government, communities and every single American—has a role in creating a healthier nation" (http://www.surgeongeneral.gov/priorities/prevention/strategy/#TheVision) (Hanna-Attisha et al., 2016) (Box 9-8: Quality and Safety Scenario).

Box 9-8

Quality and Safety Scenario

Pender's Health-Promotion Model

A health care provider's responsibility is to assess, plan, implement, and evaluate a screening program. Part of this responsibility includes teaching individuals, families, and populations about the importance of participating in these programs and ultimately engaging in safe behaviors promoting health. The health-promotion model is a useful guide for practice (Pender et al., 2015). The model presents the

interrelationship among behavior-specific cognitions and affective factors and individual characteristics and experiences that motivate individuals to engage in behaviors that promote health and decrease unsafe habits and practices. The health care provider may find that the application of this model in practice influences the relationship between the provider and the individual in a positive way. The model is a framework that assists the provider in assessing factors believed to influence health behavioral changes. Once the provider has an accurate assessment, obtained via questions, decisions may be made concerning factors that inhibit health-promoting behaviors and, ultimately, potential interventions to assist individuals in achieving positive health outcomes. This information will assist the provider to develop appropriate teaching methods.

Health-Promotion Assessment Questions

- How do you define health?
- What does health mean to you?
- How would you describe your health now?
- Do the choices you make and the actions you take affect your health?
- Can you give examples when choices and actions created a positive change in health for you?
- Can you give examples when choices and actions created a negative or unsafe change in health for you?
- What factors facilitated choices and actions that created a positive change in health?
- What factors created barriers to choices and actions that led to a negative or unsafe change in health?

- Are there any supportive personal influences in your life that would assist you in choices and actions that would create a positive change in your health (e.g., family, friends, and health care providers)?
- Are there any supportive situational influences, such as more than one plan of action, pertaining to the health change available to you?

Modified from Pender, N., Murdaugh, C., & Parsons, M. A. (2015). Health promotion in nursing practice (7th ed.). Upper Saddle River, NJ: Pearson.

The four strategic directions are:

- Healthy and safe community environments: Create, sustain, and recognize communities that promote health and wellness through prevention.
- Clinical and community preventive services: Ensure that prevention-focused health care and community prevention efforts are available, integrated, and mutually reinforcing.
- Empowered people: Support people in making healthy choices.
- Elimination of health disparities: Eliminate disparities, improving the quality of life for all Americans.

Under the second strategic direction, the strategy identifies six recommendations, including a focus on improving cardiovascular health, incorporating screenings, using payments and reimbursement to encourage clinical preventive services, and reducing access barriers to community preventive services (National Prevention Council, 2011) (Figure 9-4).

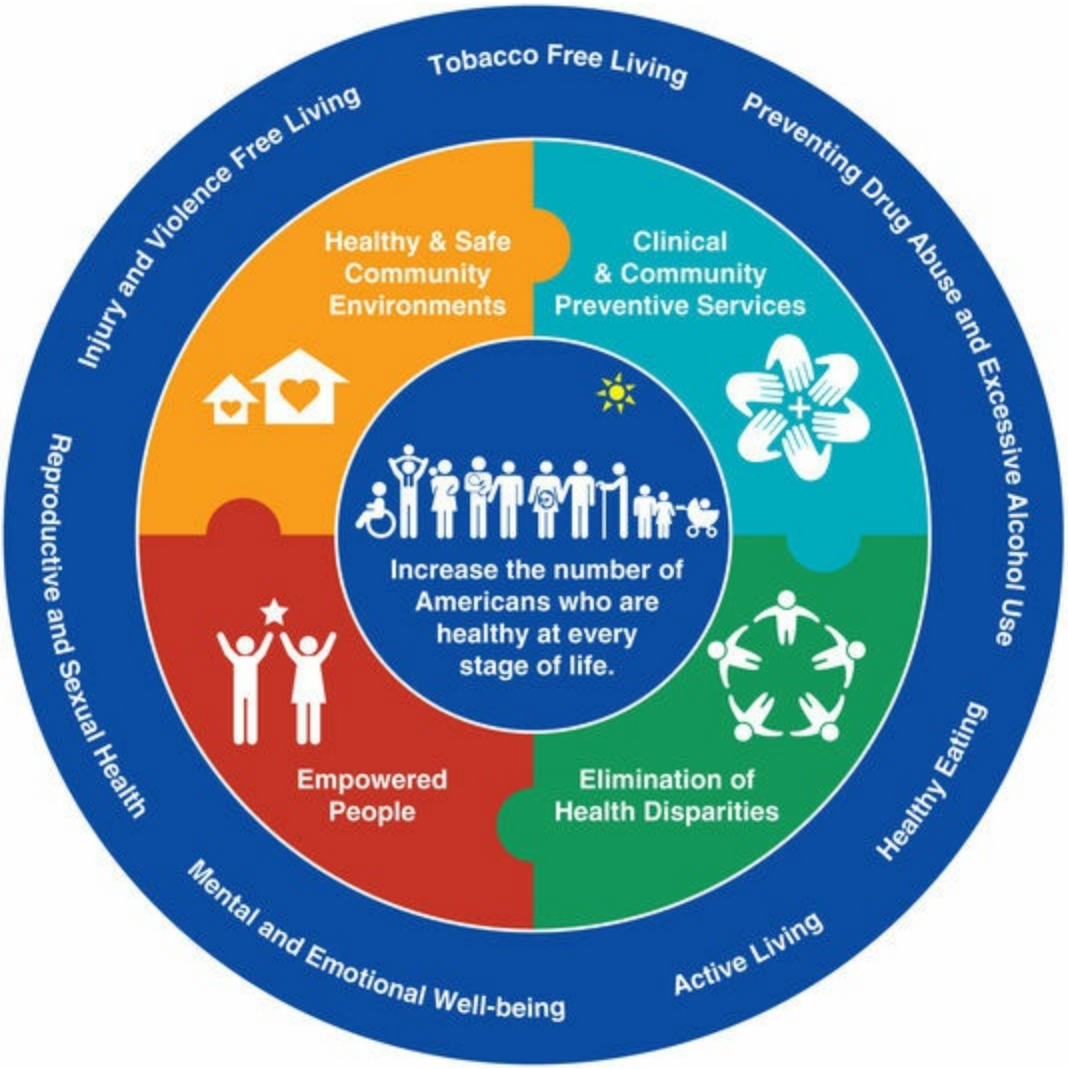

FIGURE 9-4 America's plan for better health and wellness.
(From National Prevention Council. [2011]. *National Prevention Strategy.* http://www.surgeongeneral.gov/priorities/prevention/strategy.)

The Nurse's Role

As one of the important stakeholders (Institute of Medicine, 2011), nurses play a role in every aspect of the screening program development process, including assessment, data analysis, planning, implementation, evaluation of the health outcomes, and evaluation of the process (including the workings of the partnership; see Figure 9-2). One aspect of this health process is the development and implementation of screening programs for targeted groups. As nurses use higher decision-making skills based on advancing education and expertise (Institute of Medicine, 2011), they will face questions such as "Should this condition be screened for or not?" In the role of decision maker and planner, the nurse is responsible for reviewing all issues concerned with screening individuals for an appropriate disease, including the criteria specific to the disease, the medical and economic ethics, and the community resources that are affected. If the choice is to screen individuals, the participation of nurses and other partnering groups is essential in the development of a care plan. The last step integral to the nursing role is the planning and development of an efficient referral system to enhance continuity of care and to ensure follow-up.

Because many preventive care services are provided through insurance coverage, the nurse collaborates with other health providers to ensure that preventive services (see Boxes 9-5 and 9-6), along with the required education and counseling, are available through primary care or community services such as a primary care clinic, a person-centered medical home, or a community health center or even at the work site. These services may include:

- Blood pressure, diabetes, and cholesterol tests
- Cancer screenings, including mammograms and colonoscopies
- Counseling on topics such as quitting smoking, losing weight, eating healthily, treating depression, and reducing alcohol use
- Routine vaccinations against diseases

- Flu and pneumonia immunizations
- Counseling, screening, and vaccines to ensure healthy pregnancies
- Regular well-baby and well-child visits, from birth to age 21 years

Nurses have long been responsible for screening individuals and educating people about healthy lifestyles and decreased risks as part of the ordinary primary care assessment process. Questions concerning nutrition, coping, and self-care are all assessment or screening questions, leading to moments of opportunity or "teachable moments" for health promotion. These evaluation activities are invaluable for gauging risk and potential areas for screening. Teaching individuals the meaning and limitation of screening test results is an important element of this role, as is informing them of their part in obtaining implied benefits.

Nursing staff, at all levels, are important in applying preventive services to include screening and education. The concept of the person-centered medical home encourages the use of each member of the primary health care team to the highest level of their professional and licensing abilities. The combined nursing roles of health educator and screener mean that the nurse continues to educate individuals about risk factors and teach them ways to alter and reduce risks generally through lifestyle changes, such as proper diet, exercise, and stress management, and by limiting the use of alcohol, drugs, and tobacco. The role as educator is essential in the screening process because nurses provide individuals with the information necessary for choices they will make regarding healthy behavioral change. The nurse is actually practicing primary prevention interventions, but this is done in coordination with a secondary preventive role.

Racial and Ethnic Approaches to Community Health

An excellent resource is the CDC REACH website http://www.cdc.gov/nccdphp/dch/programs/reach/. This program supports effective community-level programs to reduce health disparities in minority communities across the United States. Data from the REACH Risk Factor Survey (2009), focusing on breast and cervical cancer prevention, cardiovascular health, and diabetes management, have shown that changing health behaviors in minority communities has improved health and reduced community disparities (Box 9-9).

Box 9-9

Racial and Ethnic Approaches to Community Health US Keys to Success

Trust: Build a Culture of Collaboration With Communities That Is Based on Trust

- **Empowerment.** Give individuals and communities the knowledge and tools needed to create change by seeking and demanding better health and building on local resources.
- **Culture and history.** Design health initiatives that are grounded in the unique historical and cultural context of racial and ethnic minority communities in the United States.
- **Focus on causes.** Assess and focus on the underlying causes of poor community health and implement solutions that will stay embedded in the community infrastructure.

- **Community investment and expertise.** Recognize and invest in local community expertise and motivate communities to mobilize and organize existing resources.
- **Trusted organizations.** Enlist organizations within the community that are valued by community members, including groups with a primary mission unrelated to health.
- **Community leaders.** Help community leaders and key organizations forge unique partnerships and act as catalysts for change in the community.
- **Ownership.** Develop a collective outlook to promote shared interest in a healthy future through widespread community engagement and leadership.
- **Sustainability.** Make changes to organizations, community environments, and policies to help ensure that health improvements are long-lasting and community activities and programs are self-sustaining.
- **Hope.** Foster optimism, pride, and a promising vision for a healthier future.

Case Study

Screening

Mrs. C. is an 82-year-old white widow. Six years ago, she moved from her house into a one-bedroom apartment. Her primary insurance is Medicare. She maintains her apartment and does all her errands without assistance, all of which she is very proud. She reports that occasionally she has fallen, probably because of some degree of

decreasing vision, especially when moving from direct sunlight into shadows and when walking at night. The only medications she takes are an analgesic for pain management of osteoarthritis, an antihypertensive agent, and a daily vitamin and cranberry supplement. Her antihypertensive medication has recently been changed.

Today, she is going to her annual "check-up" with nurse practitioner (NP) Kelly, who is part of a new practice of "integrative medicine." The collaborative practice of registered nurses, NPs, and physicians emphasizes the role of prevention, including screenings. While Kelly is assessing Mrs. C.'s health status, she is also reflecting on how to better care for the practice's ever-enlarging older adult population. Kelly has access to a large referral group including medical specialists.

Reflective Questions

- What data will nurse practitioner Kelly collect to assess Mrs. C.'s health? Why?
- What risk factors will Kelly most likely evaluate? Why?
- What screening tests will Kelly suggest? Why?
- Propose several possible nursing diagnoses for Mrs. C. What possible etiological factors from Mrs. C., her family, and her community might be involved?
- What questions will Kelly ask to evaluate Mrs. C.'s health status?
- Compare and contrast these different (individual, family, and community) approaches to health promotion, emphasizing screening and cost-effectiveness.
- Discuss the advantages and disadvantages of screening older adults.

Care Plan

Health Promotion, Emphasizing Screenings of Older Adults: Mrs. C.

Caring for older adults is challenging and rewarding. New ways of caring need to be developed especially considering the increasing number of the older "baby boomer generation" in America.

*__NURSING DIAGNOSIS: Effective community therapeutic regimen management__

Definition

The pattern in which an individual, family, and/or community experiences (or is at risk of experiencing) difficulty integrating screening programs for the promotion of health and reduction of risk factors

Defining Characteristics

Major

- The individual, family, and/or community verbalizes the desire to manage health promotion with the assistance of the family and community including a nurse practitioner.
- The individual and family verbalize inadequate knowledge of health-promotion strategies, especially risk factors identified through screening methods.

Minor

- What are Mrs. C.'s screening and health-promotion needs?
- What is Mrs. C's understanding of aging and of accelerated risk factors for illness?

Related Factors

- Complexity, including discomfort, of some screenings (e.g., mammograms, osteoporosis testing)
- New ways of thinking about and delivering health promotion, including periodic screening recommended for older adults
- Shifts of resources and costs from individual providers to the community and family (e.g., self-screenings, transportation)

Interventions

- Promote attitudes of openness to new health information.
- For elevated blood pressure readings, repeat blood pressure screening on three different visits.
- Develop a more detailed activity/experience log with special attention to physical safety (falls) and vision problems.
- Explore nutritional and activity strategies that are more appealing to each individual.
- Begin the program slowly.
- Follow up on additional risk factors.
- Offer resources to support goals and interventions.

Expected Outcomes

- The person may experience anxiety.
- The person may experience despair.

Mrs. C., her family, and her community will:

- Verbalize a full understanding of health promotion, especially screenings.

Mrs. C. will:

- Identify and discuss her own risk factors and other data obtained from screenings.
- Establish appropriate goals to decrease the unhealthy findings of her screenings.
- Design and implement a modification program to fulfill these goals.
- Evaluate the efficacy of this care plan with nurse practitioner Kelly.

*NANDA Nursing Diagnoses—Herdman, T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Screening is the administration of measures or tests to distinguish individuals who may have a condition from those who probably do not have it. It is an effective, efficient tool in preventive health care if used for conditions applicable to the screening model and specifically directed toward an at-risk population.

Implementing screening programs requires coordination and planning and provides numerous places for nursing intervention, especially within the currently evolving health care environment, which is emphasizing prevention activities. Nurses can provide individuals, communities, and populations with valuable preventive, health-promotion, and health-education support in the care of healthy individuals and populations.

Health Education

Susan A. Heady

OBJECTIVES

After completing this chapter, the reader will be able to:

- Analyze the goals of health education.
- Discuss learning principles that affect health education.
- Apply teaching and learning concepts to teaching.
- Describe selected theoretical models used in health education to influence the behavior change process.
- Explain the steps in preparing a health teaching plan.
- Propose learning strategies appropriate to each learning domain.
- Discuss the importance of evaluating the educational process.

KEY TERMS

Behavior change
Ecological model
Empowerment
Health behaviors
Health belief model
Health counseling
Health disparities
Health education

Health literacy

Health promotion

Quality and safety

Self-efficacy

Social cognitive theory

Social justice

Social marketing

Transtheoretical model (Stages of change)

Think About It

The Challenges of Health Education

With personal health behavior patterns linked closely to the current causes of morbidity and death, health education is fundamental to promoting lifestyle change. People may lack the knowledge needed for making lifestyle changes, such as awareness of risks. In addition, they may not be aware of effective health-promotion strategies and resources in the community. In each encounter the nurse has the opportunity to assess the learner's needs for education related to primary, secondary, and/or tertiary prevention. Whether the target audience is an individual or a community, the nurse considers these questions in addressing the health-education needs:

- *What can people do to improve their health in the context of lifestyles?*
- *How can individuals, families, and communities make healthier choices?*
- *What is the nurse's role in facilitating health through education and program planning?*

Reflect on the following scenario. Tonya is a 14-year-old black American who lives with her mother and older brothers in a low-income housing complex in a high-risk neighborhood. Her after-school activities focus on texting her friends and watching television. Tonya is obese for her age and

height. According to the school nurse, many of her peers are also overweight or obese. Consider the following:

- What does Tonya know about healthy nutrition and exercise?
- What factors may promote or interfere with Tonya's learning or adopting a change in lifestyle?
- How can the nurse best address Tonya's health-education needs?
- What are the health-education needs of other students in the school?
- What information is relevant to teaching Tonya or planning programs for the middle school students in this neighborhood?
- Which theories can be used in planning health-education programs?
- How might families or the community be involved in supporting obesity prevention and reduction for these teens?
- What are the needs of other residents of the community?

Health education is a vital component in promoting individual and community health. Individual behaviors such as diet, physical activity level, and substance abuse play a significant role in health outcomes.

Lifestyle changes should not be viewed as only primary prevention. Chronic diseases related to health behaviors are the major causes of poor health, disability, and death, and contribute considerably to health care costs. Individual intensive lifestyle changes and strategies to address population health can be effective not only in preventing chronic diseases but also in reversing their progression and significantly reducing health care costs (Bauer et al., 2014).

Health education to promote positive behavior change, along with policies and programs that address the social determinants of health, can reduce the rates of chronic illness and disability in the United States. The *Healthy People 2020* national health objectives emphasize priorities to improve the health of individuals, groups, and

communities in the United States. These priorities involve promoting positive health behaviors, increasing health literacy, and reducing health disparities (US Department of Health and Human Services [USDHHS], 2010). Achievement of these objectives provides challenges and opportunities for health promotion.

Although many health goals are affected by individual lifestyle practices, health is influenced significantly by social, economic, physical, and political factors. The *Healthy People 2020* vision for health education includes a commitment to providing early health literacy and prevention education beginning with preschool, then continuing throughout the K-12 education continuum and beyond. This involves an approach to developing healthy citizens not only by delivering basic health-promotion and disease-prevention concepts and encouraging risk-reduction behaviors but also by demonstrating the value of interrelatedness and the connection between individual and community health (Koh et al., 2011). Box 10-1: *Healthy People 2020* includes objectives related to educational programs.

Box 10-1

Healthy People 2020

Selected Health-Promotion and Disease-Prevention Objectives Related to Educational and Community-Based Programs

Goal: To increase the quality, availability, and effectiveness of educational and community-based programs designed to prevent disease and injury, improve health, and enhance quality of life

School Setting

- Increase the proportion of preschool programs that provide health education to prevent problems in these areas: unintentional injury; violence; tobacco use; alcohol and other drug use; unhealthy dietary

patterns; and inadequate physical activity, dental health, and safety.

- Increase the proportion of elementary, middle, and senior high schools that provide comprehensive health education to prevent problems in the following areas: unintentional injury; violence and suicide; tobacco use; alcohol and other drug use; unintended pregnancy and sexually transmitted infections; unhealthy dietary patterns; and inadequate physical activity.

- Increase the proportion of elementary, middle, and senior high schools that have health-education goals or objectives that address the knowledge and skills articulated in the National Health Education Standards (high school, middle, elementary).

- Increase the proportion of elementary, middle, junior high, and senior high schools that have a nurse-to-student ratio of at least 1 : 750.

- Increase the rate of completion of high school.

- Increase the proportion of college and university students who receive information for the institution of each of the six priority health-risk behavior areas listed in the preceding fourth objective.

Work Setting

- Increase the proportion of work sites that offer an employee health-promotion program to their employees.

- Increase the proportion of employees who participate in employer-sponsored health-promotion activities.

Community Setting and Select Populations

- Increase the proportion of tribal and local health service organizations that provide population-based primary prevention

services in the following areas: injury and violence prevention; mental illness; tobacco use; substance abuse; unintended pregnancy; chronic disease programs; nutrition; physical activity.

- Increase the proportion of local health departments that establish culturally appropriate and linguistically competent community health-promotion and disease-prevention programs.

From US Department of Health and Human Services. (2010). *Healthy People 2020.* http://www.healthypeople.gov.

Nursing, with its unique contributions to health care, is a professional resource that can help facilitate these changes through health-education strategies. Nurses, in partnership with other health care professionals, can be the link between the philosophy of *Healthy People 2020* and the people who need to hear its messages and act on those messages.

Nursing and Health Education

Nurses as educators play a key role in improving the health of the nation. Educating people is an integral part of the nurse's role in every practice setting—schools, communities, work sites, health care delivery sites, and homes. **Health education** involves not only providing relevant information but also facilitating health-related **behavior change**. The nurse, using health-education principles, can assist people in achieving their health goals in a way that is consistent with their personal lifestyles, values, and beliefs.

Nursing: Scope and Standards of Practice (American Nurses Association, 2015) describes health teaching and **health promotion** as primary nursing responsibilities. This includes educating people about healthy lifestyles, risk reduction, developmental needs, activities of daily living, and preventive self-care. *Nursing's Social Policy Statement* of the American Nurses Association (2010) also addresses health teaching and **health counseling**. This responsibility to teach individuals is balanced by their right to receive information about their health status, risks, and ways to reduce their risks. The nurse provides health teaching and health counseling on the basis of individual interests and decisions to enable individuals to make informed decisions about their health.

Nurses usually function as health care coordinators for individuals in their care. Depending on the interests and needs of a person, nurses establish a partnership to guide the individual in the selection and use of relevant health services. Health-education principles provide the nurse with strategies and tools for assessing an individual's readiness for health teaching, with technical information, and with help in practicing healthy behaviors in his or her daily life. These strategies also help the nurse facilitate behavior change while satisfying the person's right to relevant health information and the freedom for people to make decisions about their own health. Health education encourages self-care, self-empowerment, and, ultimately, less dependence on the health care system.

Nurses have long been involved in public health education, taking on the full-time role of coordinating the educational services provided by a health agency or institution. As a health educator, the nurse may use marketing strategies to enhance the effectiveness of health-education programs that are focused on certain target populations. The health-education specialist helps other nurses and health professionals improve their skills in developing and delivering teaching plans.

Definition

Health education is "any combination of learning experiences designed to help individuals and communities improve their health, by increasing their knowledge or influencing their attitudes" (World Health Organization, 2016). This process involves several key components. First, health education involves the use of teaching-learning strategies. Second, learners maintain voluntary control over the decision to make changes in their actions. Third, health education focuses on behavior changes that have been found to improve health status.

Health education facilitates the development of health knowledge, skills, and attitudes through the application of theories or models. Commonly used theories of individual and community behavior change will be discussed later in this chapter. Generally, health-education strategies help ensure that individuals, as consumers of health services, are satisfied and have received the health information that is most relevant to their health risks. From a public health perspective, health-education programs are intended not only to enhance individuals' abilities to make positive lifestyle changes but also to support social and political actions that promote health and quality of life in communities.

The following scenario is an example of a therapeutic situation in which a health-education approach may be used to meet an individual's health needs.

Sada Thompson, a 21-year-old university senior, visits university health services because she wants to change her method of birth

control. She has experienced side effects from the birth control pill that she has been taking for the past year and knows little about other options. She has recently started dating John after breaking up with Steven 3 months ago. Having decided to be sexually active with John, Sada is feeling uncertain about what she needs to do to take care of herself and how to discuss this uncertainty with John. She is aware of all the talk about AIDS on campus, and she knows that John is popular and has dated several other women in school, which concerns her.

Sada needs to learn new information, she may need to acquire new skills, and she needs to clarify any feelings or attitudes that affect her decision to use a new birth control method and ensure her continued safety. After recording her health assessment history and arranging for a gynecological examination and laboratory tests, the nurse develops a teaching plan. Selecting one or more strategies for helping Sada review all the birth control options, the nurse establishes an environment in which Sada can choose to try a new method or request a change in her prescription for oral contraceptives. Together they identify actions that Sada can take to use the method properly. They also anticipate and identify ways that Sada can solve problems of adjusting to the new method.

The nurse answers Sada's immediate questions about safe sex, gives her several pamphlets written for college students about this topic, and suggests that she participate in the peer counseling night on sexually transmitted diseases that will be held on campus in 2 weeks. The peer counseling hotline number and drop-in hours are given to Sada. The nurse explains that the students who provide the peer counseling are trained to help other students talk about and deal with this important issue. The nurse invites Sada to call or come back to the office for additional help, information, and problem-solving discussion.

This example illustrates that educational interventions, in addition to direct health services, are necessary to meet the individual's goal. Although health care providers and nurses prefer that people choose to take actions that will promote health and not detract from it, the

individual determines the at-home application of health recommendations.

Goals

The goal of health education is to help individuals, families, and communities achieve, through their own actions and initiative, optimal states of health. Health education facilitates voluntary actions to promote health. Another important goal of health education is improving health literacy.

Health literacy is defined as "the degree to which individuals have the capacity to obtain, process, and understand health information and services needed to make appropriate health decisions" (USDHHS, 2016). Simply stated, "health literacy is about communicating health information clearly and understanding it correctly" (Osborne, 2013). Health literacy includes the ability to read, write, speak, listen, compute, and comprehend, and to apply those skills to health situations.

According to the 2003 National Assessment of Health Literacy study, only approximately 12% of US adults had proficient health literacy. More than one-third of US adults have only basic or below basic health literacy. This means they would have difficulty with common health tasks, such as following directions on a prescription drug label or adhering to a childhood immunization schedule using a standard chart. Although half of adults without a high school education had below basic health literacy skills, even high school and college graduates can have limited health literacy. The more vulnerable members of our communities—those with lower education levels, racial/ethnic minorities, the uninsured and publicly insured, and the elderly—have the lowest levels of health literacy (USDHHS, 2016).

Nurses, through their unique responsibility for the majority of care recipient, caregiver, and community health education and communication, can also contribute to improving health literacy by assuming a lead role in reviewing and revising all types of forms and educational materials intended for care recipients, examining these

materials for relevance, clarity, cultural appropriateness, and clinical accuracy (Baur, 2011). This includes materials available via the electronic health record.

Addressing health literacy and providing culturally sensitive health education are critical to reducing health disparities and achieving health equity. **Health disparities** are systematic, potentially avoidable health differences that adversely affect socially disadvantaged groups. The groups affected are those with characteristics such as race/ethnicity, skin color, religion, language, or nationality; socioeconomic resources or position; sex, sexual orientation, or gender identity; age; physical, mental, or emotional disability or illness; geography; political or other affiliation; or other characteristics that have been linked historically to discrimination or marginalization (Braverman et al., 2011). Examples of public health interventions to reduce health disparities in the United States include Vaccines for Children; Many Men, Many Voices, for black men who have sex with men; Healthy Love, to reduce the risk of HIV infection in heterosexual black women; and an initiative to reduce motor vehicle accidents in four Native American nations (Centers for Disease Control and Prevention, USDHHS, 2014).

People-centered care is an essential component of **quality and safety** whether health promotion is directed toward an individual, family, or community. In the planning and implementation of health-education programs, essential components include showing respect for values and cultural, ethic, and social diversity, empowering and actively involving the learners, promoting physical and emotional comfort, communicating in ways that are appropriate to health literacy and sociocultural background, and seeking continual self-improvement in effective education (Quality and Safety in Nursing Institute, 2014). Use of health-education strategies that are person centered can have a significant impact on the outcomes of health care recipients (Box 10-2: Quality and Safety Scenario).

Box 10-2

Quality and Safety Scenario

A Community-Based Person-Centered Health Promotion

The Southwest Organizing Project (SWOP) provides an example of a person-centered community-based approach designed to reduce health disparity in people of color. SWOP, a successful grassroots organization, combats childhood obesity in low-income families in Albuquerque, New Mexico, by targeting population-level causes of obesity.

SWOP tailored health promotion to the community using an innovative three lens health-promotion framework based on the Robert Wood Johnson Foundation's Communities Creating Health Environments initiative. The three lenses used to organize the community to advocate for a healthy sustainable environment included social justice, culture-place, and organizational capacity–organizing approach. **Social justice** refers to fair treatment, equal access to goods and resources, and the right to self-determination and cultural expression for all people. The social justice lens is used to identify the structural cause of the targeted health disparity. The culture-place lens, the "total way of life of a people" (values, rituals, patterns of thinking, and group identity), as well as the place characteristics (geography, history, political), determines culturally and geographically meaningful and responsive interventions to address the population cause. Organizational capacity–organizing approach, the capacity of a grassroots organization to organize resources and strategies, determines the most effective strategy to align the interventions and organization to promote health in the targeted area.

For example, in Albuquerque, application of the food justice perspective identified the structural cause of the childhood obesity as limited access to locally grown healthy foods and lack of fresh produce in school lunches. Cultural and geographical analysis indicated tailoring the project to the demographics of the children,

Hispanic and blended Hispanic Native American from a historically farming culture. In addition, because of strong support from several legislators, the state legislature was targeted to support a healthy school lunch policy rather than Albuquerque city council or school board. SWOP's organizational capacity analysis revealed adult and youth leaders, alliance with key community organizations, established relationships with city and state councils, and limited relationships with school decision makers. Community interventions included involving leaders and residents in establishing an urban community garden, education in farming, gardening, and healthy eating, forming alliances with community stakeholders, and advocating a healthy school lunch policy.

SWOP used a three-lens framework to develop and implement interventions centered on the health-promotion needs of the obese children in the Albuquerque community. Community-based health-promotion interventions, such as SWOP, involving nurses and key leaders in partnering with the community, empower communities of color to take long-term action to reduce health disparities.

Data from Subica, A. M., Grills, C. T., Douglas, J. A., & Villanueva, S. (2016). Communities of color creating healthy environments to combat childhood obesity. *American Journal of Public Health*, *106*(1), 78–86.

Health education encourages positive, informed changes in lifestyle behaviors that prevent acute and chronic disease, decrease disability, and enhance wellness. Another goal of health education that may foster successful changes in health behavior is **empowerment**. People who believe that they can make a difference in health and who are involved in decision-making are more likely to make changes (Anderson & Fallin, 2012).

Changes in health behaviors that are related to health education help prevent disease and disability. Two main objectives of health education and health counseling are to change health behaviors and to improve health status. Information alone does not change behavior.

Health education and health counseling are mutually supportive activities. Health educators often use one-to-one and group

counseling techniques as strategies for active health learning. Counselors may refer people to health-education resources or assist them in acquiring information pertinent to solving a health problem. The following example helps illustrate the goals of health education. The general principles of learning that are found in Box 10-3 are fundamental to the planning of successful health-education programs.

Box 10-3

How to Facilitate Learning

- Use methods that stimulate a variety of senses.
- Involve the person actively in the learning process.
- Establish a comfortable, appropriate learning environment.
- Assess the readiness of the learner, which may be affected by physical, social, emotional, and financial factors.
- Make the information relevant by connecting with the existing needs and interests of the learner.
- Use repetition. Review and reinforce concepts several times in a variety of ways.
- Make the learning encounter positive. Structure it to achieve progress recognizable by the individual and provide frequent, positive feedback.
- Start with what is known and proceed to what is unknown, moving from simple to complex.
- Apply the concepts to several settings to facilitate generalization.
- Pace the learning appropriately for the individual.

Kate Hanson, aged 22 years, visits the local family health center for fatigue and symptoms similar to influenza. During the assessment with the nurse, Kate discloses that she has missed her last two periods.

The physical examination findings, the laboratory test findings, and the health assessment pattern confirm Kate's suspicions of pregnancy. Psychosocial evaluation reveals that Kate works part-time as a secretary for a temporary agency and lives in an apartment with her recently unemployed husband, Jim. Further interviewing reveals that Kate has minimal knowledge of prenatal care; she has a diet of take-out food that is high in fat, sodium, and sugar, with infrequent consumption of fresh fruits or vegetables; and she has three or four beers on the weekends. Kate has never taken vitamin supplements, she leads a sedentary lifestyle, and she is obviously overwhelmed by the news that she is pregnant.

The nurse first takes steps to create a safe and trusting atmosphere in which Kate can feel free to share her concerns and apprehensions. When Kate expresses concerns about telling her husband about the pregnancy, the nurse discusses this with her. Kate is then taught the importance of taking a multiple vitamin with an iron supplement daily, discontinuing the consumption of alcohol, checking with her physician before taking medications, and making time for more rest during the day. Sensing that this is all that can be accomplished at this time, the nurse gives Kate two pamphlets on prenatal care and makes an appointment for her to return in 1 week with her husband. Kate acknowledges that she understands the instructions, and the nurse documents the teaching and recommendations in Kate's medical record.

During the next visit, the nurse meets Kate and Jim, explores the meaning of the pregnancy in their lives, and helps them identify actions they will need to take. The recommendations that were made during Kate's first visit are reviewed and reinforced. The nurse then details specifics of dietary changes, reinforces the need for proper rest and exercise, and helps the couple solve problems while they adjust to these new responsibilities. Most importantly, the nurse gives them

information on the clinic's weekly prenatal classes and explains that because the classes are partially covered by local community funding, the charge is minimal. The classes include information about physical changes, psychosocial changes, and nutritional needs during the pregnancy, the labor and delivery period, and the newborn and postpartum periods. A nurse practitioner conducts the classes at the clinic, which are given in a group format to facilitate social support and problem-solving among expectant parents.

The nurse gives Kate and Jim several other pamphlets to read at home, makes a clinic appointment for Kate in a couple of weeks, and encourages her to call if she has questions or concerns in the interim. A schedule of the prenatal classes is reviewed, and a date for the next session is made. The couple is encouraged to meet the social worker to explore their financial needs and options because Jim was recently laid off. Kate and Jim acknowledge that they understand what they need to do, and the nurse documents what was taught and discussed in Kate's health care record.

This example illustrates the goal of health education: to help individuals achieve optimal health and well-being through their actions and initiative. Through health education, individuals can learn to make informed decisions about personal and family health practices and to use health services in the community. The couple in this example receives educational assistance from the nurse that will promote better health and well-being for Kate and their baby.

Learning Assumptions

Chapters 16 to 24 in this text address the factors one should consider when teaching different age groups and the learners' respective characteristics to consider when one is developing a teaching plan.

The nurse considers the developmental stage, cognitive level, and interests of the individual. The level of information to be conveyed and the skills and abilities of the individual will guide the methods and resources used.

Family Health Teaching

The family plays an important role in health and illness. Because the family is the unit within which health values, health habits, and health risk perceptions are developed, organized, and performed, individual's health, understanding, and intervening with the family is essential to promoting health and reducing health risks in individuals and communities (Anderson & Fallin, 2012). Skills in family interviewing and assessment are valuable tools for nurses. Family health assessment and health teaching are closely related. The assessment model in Chapter 6 provides a comprehensive approach to identifying problems, strengths, and health-education needs. The goal is to help the members achieve optimal states of health while guiding them through problem-solving and decision-making. This process empowers them. Members believe they can make a difference in their own health.

In clarifying the health teaching needs of a family, the nurse might ask herself/himself the following questions: "Who is in this family? What health-related tasks are they performing? How are they functioning and how are they meeting each other's needs? How well are they communicating? What does this family need to know? What do they need to know now? What do they think they need to know? How can they learn what they need to know?"

The nurse works with the family to set a broad health-promotion goal for the family, then directs the health teaching toward a more specific area. It is essential that the family agrees with the goal and teaching needs. As the family participates in the assessment interview, perhaps members can identify their own health teaching needs. Health teaching includes all family members, with learning activities appropriate for each individual. The general teaching goal will be the same for all members, but the approaches and specific goals for each member or subsystem will be different. Children, adolescents, and elderly members pose special challenges to the nurse, who may be geared toward teaching young or middle-aged adults (Figure 10-1).

FIGURE 10-1 School-age children will engage in safe travel.

Health Behavior Change

The process of health education directs people toward voluntary changes of their health behaviors. Viewing health behavior through an **ecological model**, the nurse recognizes the complex interaction of individuals with their environment and the multiple influences of the individual, the interpersonal group, and the community on health behavior. This section examines the use of commonly used models of individual health behavior change. Community and group models in health-education planning are addressed later in this chapter.

Individual models of health behavior help explain factors influencing and interfering with positive health behaviors. In addition, they contribute to understanding how educational intervention supports behavior change.

Beliefs, attitudes, values, and information contribute to motivation and behavior and are underlying factors in the making of any decision to change behavior (Richards, 2014). **Health behaviors** are any activities that an individual undertakes to enhance health, prevent disease, and detect and control the symptoms of a disease. Identifying

and teaching people about lifestyle behaviors that need to be changed is only the first step in the process of assisting individuals in moving from knowledge to action. Nurses apply concepts from the health belief model, social learning theory, and the transtheoretical model (TTM) in subsequent steps to formulate an action plan that meets the needs and capabilities of each person in making healthy behavior changes.

Health Belief Model

The **health belief model** is a paradigm used to predict and explain health behavior. The following components of the health belief model provide guidelines for nurses to analyze factors that contribute to a person's perceived state of health or risk of disease and to the individual's probability of making an appropriate plan of action:

- individual perceptions of susceptibility to a health condition or disease;
- perceived seriousness of the disease;
- perceived benefits of health action;
- perceived barriers to the health action;
- cues that promote action (feelings or media responses);
- perceived ability to perform the action (Rosenstock et al., 1988; Skinner et al., 2015).

Application of components of the health belief model generates data to assist nurses in choosing effective educational strategies. The nurse then determines the most appropriate interventions for a particular person through collaboration with the individual.

Social Cognitive Theory

Social cognitive theory is another model that adds to the understanding of the determinants of health behavior. Bandura (1997) emphasizes the influence of self-efficacy, or efficacy beliefs, on health behavior. **Self-efficacy** refers to an individual's belief in being personally capable of performing the behavior required to influence

one's own health (see the case study and the care plan at the end of this chapter). Social cognitive theory also describes the roles of reinforcement and observational learning in explaining health behavior change. Modeling, or providing opportunities for imitating the behavior of others, can be used to demonstrate the desired behavior.

Transtheoretical Model of Change

The **transtheoretical model** (TTM) or **"stages of change model,"** is useful for determining where a person is in relation to making a behavior change (Prochaska & DiClemente, 1984). According to the TTM, health-related behavior change progresses through the following five stages regardless of whether an individual is quitting or adopting a behavior:

- Precontemplation: The person is not thinking about or considering quitting or adopting a behavior change within the next 6 months (not intending to make changes).
- Contemplation: The person is seriously considering making a specific behavior change within the next 6 months (considering a change).
- Planning or preparation: The person who has made a behavior change is seriously thinking about making a change within the next month (making small or sporadic changes).
- Action: The person has made a behavior change, and it has persisted for 6 months (actively engaged in behavior change).
- Maintenance: The period beginning 6 months after the action has started and continuing indefinitely (sustaining the change over time) (Prochaska et al., 2015).

The TTM is useful in determining the person's readiness for learning in relation to changing a behavior so that health education or behavior change interventions can be matched to the stage. Self-efficacy is a key construct in this model. This model also acknowledges the importance of continuing intervention to

maintaining behavior change long term. The TTM has been used by health professionals in planning interventions with a wide variety of people at risk.

Regardless of the quality of nurses' assessment methods and educational strategies, experience in the area of health education indicates that people do not always make the choices recommended to them by health professionals or adhere to the healthy changes. Naturally, health professionals want people to choose the recommended course of action, but each individual has the right to choose not to follow advice. Enlisting the individual's partnership or cooperation achieves better results.

Attempts to influence a person's behavior through education are not always successful. Attempting to persuade people to change their behavior to something that might make them, their friends, and their family healthier can be discouraging and sometimes futile. An individual's values, beliefs, and life stresses may present obstacles to these changes. Effective health education requires an understanding of the influential factors affecting the individual's decision-making (values, beliefs, attitudes, life stresses, religion, previous experiences with the health care system, and life goals). Another key factor in the ability to comply with health education is financial constraints. The individual may not have the resources to pay for a proper diet or may not have a safe, convenient place to exercise.

Many health professionals tend to view a person's cooperation with the health care regimen as a single choice, when this cooperation often involves many choices every day. For example, following a low-fat, low-cholesterol diet involves constant, and often inconvenient, choices throughout the day. The expectation is that people will do this every day for the rest of their lives, even when the nurse cannot guarantee health as a result.

Ultimately, the nurse needs to respect a person's right to choose. However, nurses can increase an individual's motivation and capabilities to change by involving the individual in planning and goal setting, providing information that is understandable and acceptable, and assisting the person in developing new skills.

After clarifying behaviors that a person is willing to change, the nurse can use the following framework for developing interventions for behavior change:

- Assess the behavior.
- Educate the person about the need for and benefits of change.
- Motivate the person using personalized messages.
- Assess and increase the person' self-efficacy.
- Assess and offer resources to decrease barriers to change.
- Assist the person with goal setting to modify behavior.
- Practice the skills needed to change behavior.
- Plan ways to monitor and maintain the behavior change.

Theories of health behavior change are at the heart of health education. The theories presented in this section help nurses to assess an individual's stage in the behavior change process and to develop appropriate teaching plans. The goals of the teaching plans and the strategies selected will differ depending on the factors affecting the individual's readiness to learn and to change.

Ethics

Applying principles of respect, autonomy, justice, and beneficence, nurses have an active role as advocates in empowering care recipients to make their own informed decisions about their health and care. The nurse works as a partner, facilitator, and resource for the person and family (Burkhardt & Nathaniel, 2014). Although the focus of health education may be on the behavior change process, the nurse needs to exercise caution in using tools of persuasion in communication with people because of the potential for manipulation and coercion, particularly when addressing different cultural or minority groups (Simons-Morton et al., 2012).

However, when planning health education to promote health, nurses experience several ethical dilemmas.

Choices about health care practices belong to individuals not health care providers. All competent people have the right to autonomous

choice. Nurses should respect decisions made by people and their families, even when the choice is not what the nurse might do or suggest or is considered "unhealthy." The nurse and the family should work together on a mutually agreed on plan that incorporates these individual and family values and beliefs (Burkhardt & Nathaniel, 2014). When health promotion focuses on individual behavior, disregarding other social factors that may contribute significantly to the problem, this can inadvertently lead to victim blaming. Defining a problem as simply an individual problem suggests the individual is responsible for both the problem and the solution (Simons-Morton et al., 2012).

The role of the nurse is to facilitate a communicative environment in which people can exercise their right to make informed free choices. Individuals need to participate in the decision-making process when their lives may be influenced by a change.

Although each person's state of health affects family members and the community, individuals are responsible for their own health maintenance. Health professionals need to accept and welcome individual differences in meeting this responsibility. By selecting interventions that create an environment of open communication and risk-taking, individuals can better develop the problem-solving skills to direct their own growth and development.

Genomics and Health Education

Advances in genetics and genomics present new opportunities and responsibilities for nurses in health education. Routine use of genetic and genomic technologies requires nurses to incorporate information about and implications of the technologies into educational programs for vulnerable individuals, families, and populations. Although an increasingly wide range of situations include the need for the nurse to be prepared to discuss genetics and genomics, the primary focus for nursing is health promotion, symptom management, and disease prevention. Box 10-4: Genomics describes the current role of the nurse in providing genomics education.

Box 10-4

Genomics

The Nurse's Role in Health Education

Currently the role of all nurses in providing competent genomics education involves:

- Becoming knowledgeable about basic genetic and genomics information relevant to their practice setting and population
- Identifying risks based on three-generation family history (pedigree)
- Recognizing ethical issues such as the right to determine what information to disclose to whom
- Discussing genetic or genomic factors revealed by the history that increase the risk of disease or may guide the selection of treatment options
- Explaining the difference between genetic screening and genetic testing (screening indicates a level of risk, whereas testing provides definitive diagnosis)
- Clarifying the meaning of test results and the implications for the family
- Understanding how family values and experience influence understanding of genetic/genomic facts, the difficult nature of decision-making, and the variability in personal risk interpretation
- Providing reliable sources for genetic education such as Genetics and Genomics for Patients and the Public (https://www.genome.gov/17516481)
- Cautioning the client about the use of direct-to-consumer testing

because of the possible lack of information about validity, counseling, confidentiality

- Referring individuals to the appropriate level of professional help for further information

From Lea, D. H., Skirton, H., Read, C. Y., & Williams, J. K. (2011). Implications for educating the next generation of nurses on genetics and genomics in the 21st century. *Journal of Nursing Scholarship*, *43*(1), 3–12.

Diversity and Health Teaching

The increasing racial and ethnic diversity of the US population, as well as the challenge to eliminate disparities in the health status of people of diverse backgrounds, demands that we provide culturally appropriate health education and health promotion. Individuals' cultural groups influence their beliefs about health, perceptions of disease and illness, help-seeking behaviors, and attitudes toward health providers, and play a role in their use of traditional and complementary healing practices. Prevention strategies must address each group's unique culture, experiences, language, age, sex, and sexual orientation and be culturally and linguistically appropriate for them to be effective (Perez & Luquis, 2014).

Another challenge for health professionals is to apply health-education strategies with people from diverse cultural backgrounds, people who do not speak English as their native language, and people with limited health literacy levels (Box 10-5: Innovative Practice).

Box 10-5

Innovative Practice

Empowering Rural Low-Income Mothers

Rural women often face health challenges such as limited access to care, poverty, and increased rates of obesity. A participatory project focused on empowerment by engaging mothers in designing health

messages that appealed to them. The empowerment process addressed self-efficacy and personal control, positive and negative reinforcement, and barriers specific to the mothers' everyday lives.

Forty-three low-income mothers from different racial and ethnic groups from rural counties in eight states participated in focus groups. They discussed food security, physical activity, and oral health. From the discussions, the main elements of health messages preferred by the mothers emerged. They wanted the spokesperson to be a combination of a peer with facts from an authority. Most of the mothers preferred that messages focus on positive results of doing a health behavior rather than negative results of not doing it. The mothers insisted that messages be simple and fit in with and show empathy for their hectic daily lives. The voices of these rural low-income mothers illustrate how educational messages can be co-created with the target group that are culturally relevant and meaningful.

From Aldoory, L., Braun, B., Maring, E. F., Duggal, M., & Briones, R. L. (2015). Empowerment in the process of health messaging for rural low-income mothers: An exploratory message design project. *Women & Health*, *55*, 297–313.

Nurses also need to provide a welcoming environment for the lesbian, gay, bisexual, and transgender community. This involves, but is not limited to, using inclusive language (such as “partner” rather than “spouse” and “relationship status” instead of “marital status”), not making assumptions, and respecting each person's sexual self-identity (Perez & Luquis, 2014).

The health professional needs to take the time to assess cultural beliefs that influence social and health practices and make an effort to analyze educational interventions that are acceptable and satisfying to the individual. Social marketing processes and the diffusion of innovations model discussed in the next section help one identify characteristics, interests, and concerns of target populations.

When teaching people of different cultural, racial, and ethnic groups, the nurse endeavors to provide culturally sensitive education. Nurses recognize that the person's or group's background, beliefs, and

knowledge may differ significantly from their own and seek to understand and show respect for these differences (Degazon, 2012) (Box 10-6: Diversity Awareness).

Box 10-6

Diversity Awareness

Cultural Aspects of Health Teaching

When There Is a Language Barrier

- Use courtesy and a formal approach.
- Address the person by his or her last name.
- Introduce yourself, pointing to yourself as you give your name.
- Project a friendly attitude with a smile and a handshake.
- Speak with a moderate tone and volume.
- Attempt to use words in the person's language, which indicates respect for the individual's culture.
- Use simple, everyday words rather than complex words, medical jargon, or colloquialisms.
- Use hand gestures to help the person understand.
- Instruct the person in small increments.
- Have the person demonstrate understanding of the message.
- Provide written instructions for the person to take home.
- When available, use flash cards and phrase books in other

languages.

- Use qualified health care interpreters.[a]

Areas to Consider in Cultural Assessment

- Individual's identification with a particular cultural group
- Habits, customs, values, and beliefs
- Language and communication patterns
- Cultural sanctions and restrictions
- Healing beliefs and practices
- Cultural health practices
- Kinship and social networks
- Nutritional beliefs, food preferences, and restrictions
- Religious beliefs and practices related to health
- Attitudes, values, and beliefs about health (Andrews & Boyle, 2008)[b]

Community and Group Health Education

When nurses begin to teach groups of people, they automatically enter a program planning and administrative process. When an organization wants to offer an ongoing health-education program for a target population, social marketing provides a strategy for reaching members of the group and implementing a service that will satisfy these members as consumers. Principles of social marketing and health-education strategies are combined to promote population-based changes in behavior to improve health. Concepts from community group health behavior change models and health-education strategies are combined to promote population-based changes to improve health.

Social marketing is defined as "a process that uses marketing principles and techniques to influence priority audience behaviors that will benefit society as well as the individual. The process relies on creating, communicating, delivering, and exchanging offerings that have value for individuals, clients, partners, and society at large" (Joint Committee on Health Education and Promotion Terminology, 2012). The primary objective of social marketing is to change behavior. Social marketing provides a strategy for reaching members of the group and implementing a service that will satisfy these members as consumers.

Social marketing communication reaches beyond the individual level to influence social conditions, policy, legislation, and normative group behavior. Key attributes of a social marketing approach are the offering of benefits and the reduction of barriers to influence the target group's behavior. Social marketers attempt to modify the attractiveness of specific behavioral options to favor one choice over competing alternatives. The systematic approach to understanding and responding to specific audience characteristics makes the messages more appealing (Storey et al., 2015). Social marketing

strategies could be used in designing programs for health promotion (tobacco use, obesity), injury prevention (seat belt wearing, gun storage), and environmental protection (pesticides, water conservation) (Cheng et al., 2011). Any information about the target population that is generated by social marketing strategies will improve the nurse's ability to develop effective educational interventions.

Another model commonly used in community health-education planning is the diffusion of innovations model (Rogers, 2003), which explains how an idea or product is adopted and spreads through a social system. In public health, diffusion of innovations is used to address the factors that support or inhibit the adoption of effective, evidence-based interventions to improve community health. Practical application of the model involves understanding the target population and recognizing the importance of achieving a good fit among the characteristics of the innovation, the community adopting it, and the context or environment for change. (Brownson et al., 2015).

Teaching Plan

Preparation for teaching a group program, such as a seminar or course, begins after the marketing and administrative plans are well under way. These activities ensure that there are enough participants for the program, and they provide the structure for developing the teaching plan—the program objectives, available time, human and material resources, and so on. When the marketing and administrative functions have been provided by others, and when educational strategies are developed for one person at a time, the nurse can concentrate efforts on developing the teaching plan.

A health teaching plan may emphasize a phase of the behavior change process that is related to the individual's or group's health-promotion needs or problems. The written teaching plan represents a package of educational services provided to a consumer or student. The plan is written from the learner's point of view (Box 10-7).

Box 10-7

Steps in the Teaching-Learning Process

- Assessment
- Learner characteristics
- Learning needs
- Development of expected learning outcomes
- Development of a teaching plan
- Content

- Teaching strategies, learning activities
- Implementation of the teaching plan
- Evaluation of expected outcomes
- Achievement of learning outcomes
- Evaluation of the teaching process

The process of generating a teaching plan helps the nurse recognize and use methods of learning that involve the individual as an active participant. The plan includes a list of specific actions or abilities that the person may perform at intervals during and at the end of the educational intervention. Teaching plans help nurses clarify these outcomes. Preparing a teaching plan involves the steps of the teaching-learning process outlined in Box 10-7.

Assessment

Assessment, the first step in the process, involves determining the characteristics of the learner and identifying learning needs. The following characteristics of the learner are important for the nurse to identify and consider in planning:

- Age, developmental stage in the life cycle, and level of education
- Health beliefs
- Motivation and readiness to learn
- Health risks and problems
- Current knowledge and skills
- Barriers and facilitators to learning

The reader is encouraged to refer to the chapters (see Unit 4) about individual development.

Assessment of the learner can be accomplished by one answering

the following five questions:

- What are the characteristics and learning capabilities of the individual?
- What are the learner's needs for health promotion, risk reduction, or health problems?
- What does the person already know and what skills can the person already perform that are relevant to the health needs?
- Is the learner motivated to change any unhealthy behaviors?
- What are the barriers to and facilitators of health behavior change?

When preparing a teaching plan for one person in a primary care setting, the nurse may learn background information about the individual from that person's record and agency reports that include descriptions of the person's population group. Nurses often agree to teach health classes that others have organized. In this case the nurse asks for project reports that provide marketing and needs-assessment information about the students who are expected to attend the classes (see the care plan at the end of the chapter).

Determining Expected Learning Outcomes

To determine the expected learning outcomes of a health-education intervention, the nurse answers the following questions:

- What broad public health and social goals guide the proposed educational program?
- What are the participant's learning goals?
- What does the learner need to know, do, and believe to progress through the behavior change process?

Program Goals

The program goals of a health-education project reflect the desire to facilitate improvement in some health problem or social living condition. Program goals are broad statements on long-range expected accomplishments that provide direction; they do not have to

be stated in measurable terms (Miller & Stoeckel, 2011).

Learning Goals

Learning goals are best established when the student and the nurse work together. These goals reflect the health behavior or health status change that the person will have achieved by the end of an educational intervention. Learning goals relate to the program goals.

Learning Objectives

Learning objectives indicate the steps to be taken by the individual toward meeting the learning goal, and may involve the development of knowledge, skill, or change in attitude. Objectives are most useful when stated in behavioral terms and when they contain the following components: the learner and a precise action verb that indicates what the learner will be able to do; the conditions under which the task is performed; and the level of performance expected (Bastable & Alt, 2014). Learning objectives guide the selection of content and methods and help narrow the focus of a teaching plan to more achievable steps; they also aid in setting standards of performance and suggesting evaluation strategies.

Selecting Content

To select appropriate content for a health-education program, the nurse considers what information, skills, and attitudes need to be taught and the level of learning to be achieved.

Three Domains of Learning

Content is commonly divided into three domains: cognitive; psychomotor; and affective. Cognitive learning refers to the development of new facts or concepts, and building on or applying knowledge to new situations. Psychomotor learning involves developing physical skills from simple to complex actions. Affective learning alludes to the recognition of values, religious and spiritual

beliefs, family interaction patterns and relationships, and personal attitudes that affect decisions and problem-solving progress.

To learn or change a health behavior, a person may need to acquire new information, practice some physical techniques, and clarify the ways in which the new behavior may affect relationships with others. The nurse's role is to select a combination of content from the three domains that is appropriate to meet the behavioral objective. To find samples of content for a teaching plan, the nurse researches resource materials, such as books, teaching guides, journal articles, pamphlets, and flyers created by nonprofit agencies and professional organizations. The nurse is careful about giving students materials with technical vocabulary that is too complex for the audience.

Examples of Learning Objectives

In writing learning objectives, the nurse selects action verbs from the taxonomies previously mentioned that indicate observable learning. In Table 10-1 examples are given for objectives in each domain of learning. The first objective listed for each domain is incorrect because the verb does not indicate observable learning. The second example for each domain is measurable because the verb used (indicated in boldface type) allows the learning to be observed.

TABLE 10-1

Examples of Nonmeasurable and Measurable Objectives

Domain	Objectives
Cognitive	**Not measurable:** Dan will understand the correct food choices for following a low-fat diet **Measurable:** Dan will correctly **select** low-fat foods from the options provided
Affective	**Not measurable:** Dan will demonstrate the importance of weight loss **Measurable:** Dan will **verbalize** the importance of weight loss
Psychomotor	**Not measurable:** Dan will know how to determine a serving **Measurable:** Dan will **demonstrate** correct measurement of a one-serving portion

When preparing a teaching plan, the nurse differentiates between information the individual needs to know and information considered helpful to know to develop appropriate learning objectives. This process provides cues to the nurse for planning effective strategies for

the necessary level of learning. As the level of learning to be achieved becomes complex, the educational strategies and methods selected involve the individuals in more active application and analysis of the content.

Designing Learning Strategies

Designing the learning strategies for an educational intervention involves selecting the methods and tools and structuring the sequence of activities. The teaching plan to this point provides the foundation on which to base the activity selection and sequence. The following questions guide the design of learning strategies:

- What are some basic considerations for selecting teaching methods for health-education programs?
- How does the nurse, as instructor, establish and maintain a learning climate?
- What actions can the nurse perform to increase the effectiveness of the learning methods?
- What are the appropriate methods for each learning domain?
- What methods tend to promote behavior change?

Teaching Strategies

Numerous strategies for teaching are available (Table 10-2). A few of those most commonly used are listed and described here. Lecture is a well-known method in which the teacher verbally presents information and instructions to the person or audience. Lecture provides a way to present a large amount of information to a number of people in a nonthreatening way. This can be an effective method if active learning strategies such as questioning are integrated. Discussion involves interaction between the nurse educator and the individuals. The nurse prepares questions in advance to guide the discussion. This method allows an opportunity for the nurse to gain a better perception of the individuals' understanding of the topic and to clarify the information.

TABLE 10-2

Domains of Learning, Teaching Strategies, and Examples of Desired Outcomes Related to a Behavior Change

Domain of Learning	Teaching Strategies	Examples of Desired Outcomes Related to a Behavior Change
Cognitive (thinking)	Lecture One-to-one instruction Discussion Discovery Audiovisual or printed materials Computer-assisted instruction	Describes and/or explains information relevant to the behavior change
Affective (feeling)	Role modeling Discussion Role playing Simulation gaming	Expresses positive feeling, attitudes, values toward changing the behavior
Psychomotor (acting)	Demonstration Practice Mental imaging	Demonstrates performance of skills related to the behavior change

Demonstration and practice is used in learning psychomotor skills such as performing exercises. The nurse demonstrates the expected behavior while the person observes. Then the nurse watches and provides feedback and encouragement while the person performs the behavior. Using the actual equipment that the individual will use in his or her home facilitates successful performance. For complex tasks, teaching a few steps at a time, in sequence, aids skill development.

Simulation gaming may involve computer learning, board games, or role play. Obviously, computer learning games are dependent on the availability of hardware and software appropriate for the individual and the topic. Simple board games can be developed for cognitive learning. An example might be the development of a bingo game based on the food pyramid. Role play involves acting out a potential scenario. This allows individuals to practice appropriate responses to challenging situations. For example, a person restricted to a low-fat diet can act out a response to being offered dessert by an insistent family member or friend played by the nurse (Figure 10-2).

FIGURE 10-2 Woman using the Internet as a source for health information. (From Young-Adams, A. P. [2011]. Kinn's the administrative medical assistant, an applied learning approach [7th ed.]. St. Louis: Saunders.)

Considerations for Selecting Methods

The nurse's first consideration is to promote an environment and use methods that foster self-directed learning. An active participant usually learns more.

There will be many learning styles in a group audience; therefore the nurse varies the teaching methods used in a given session. Taking into consideration the characteristics of the population (developmental stage, age, and knowledge of the topic), the nurse selects teaching methods that best support the goals and theme of the educational program. The order of content proceeds from simple ideas and skills to the more complex concepts, from known material toward lesser-known data. The nurse is sensitive to the energy level and anxiety of the audience when presenting content that requires strong concentration or causes anxiety.

Learning Climate

For group presentations the nurse addresses several activities when seeking to establish an environment that is conducive to health behavior change. The first activity is creating a sense of preparedness and organization by providing physical facilities with adequate furnishings and suitable audiovisual materials and handouts. Even the instructor's appearance will lend credibility or distraction to the presentation.

The second activity involves anticipating the needs of the group and communicating information about the schedule and the facilities. This action alleviates the group's apprehension and makes the group members more comfortable.

The third activity focuses on the nurse's assessment of the individual and group learning needs, possibly through questions and dialogue. Members of the group need to believe that the program will be beneficial and relevant to their situations. The instructor watches for and reinforces signs of motivation to participate in the experience.

Fourth, having established a positive learning climate, the nurse seeks to maintain a high level of motivation, a sense of individualized attention, and a progression. As a reality check, the nurse might ask for periodic feedback from the group about the effectiveness of the program and its relevance to group needs.

Finally, the nurse works with the group to maintain the learning climate. This process involves observing group interactions, helping individuals to participate, intervening to help the group deal with controlling its members, and remaining cognizant of dynamics in the group process that will facilitate or inhibit learning.

Teaching for Each Learning Domain

As mentioned, teaching is directed toward one or more of three learning domains: cognitive, psychomotor, and affective. Examples of appropriate teaching strategies for each domain and the expected outcomes in relation to behavior change are summarized in Table 10-2.

Evaluating the Teaching-Learning Process

The teacher can evaluate the learning, or measure achievement of learning objectives, in all domains through the use of written or oral testing, demonstrations, observation, self-reports, and self-monitoring. Teaching methods for one domain may overlap those for another domain.

The nurse can incorporate written, verbal, and nonverbal techniques for obtaining feedback about teaching performance into the teaching plan. End-of-program questionnaires are the usual method for obtaining written feedback. The nurse may ask for verbal feedback at various times from the group, from individual students, and from observers of the class. Nonverbal communication cues from participants may indicate their satisfaction, fatigue, or frustration with the educational intervention.

The overall process of the teaching-learning experience needs to be evaluated. The procedures used to organize and promote an educational program can affect its ultimate success. The nurse (or a program administration committee) records activities such as advertising, registration, fee collection, and availability and repair of equipment and materials. This evaluative information can then be used to improve subsequent programs. Surveys by telephone or by questionnaires help obtain the consumer's opinion about these implementation procedures. Word-of-mouth referrals to future programs and support from other community agencies and professionals may also indicate approval of the program format.

Occasionally the nurse is asked to justify a health-education program in terms of its effect on the community's public health goals or social problems. Health promotion involves a combination of health-protection activities, preventive health services, and health-education programs; therefore drawing a direct correlation between an educational intervention and the statistical improvement of the health problem can be difficult.

Nurses can often describe the theoretical influence of an educational intervention on health behaviors, health problems, and social problems. Statistics such as the number of people served each year,

the percentage of the target population reached, the number of service providers used, and the number and cost of programs are important and need to be preserved. As these statistics change over time, the data will provide cues to program successes and problems.

Referring Individuals to Other Resources

The end of a teaching plan includes resources for people to use for continuing education, counseling, peer support, and health services. Nurses encourage people to view health education as a lifelong learning process. Each person has different developmental needs and health concerns through the life cycle. Moreover, any one educational intervention may help a person move only from one phase of the behavior change process to the next. Additionally, the Internet as a health-education tool may influence a person's health practices.

Teaching and Organizing Skills

To develop teaching and organizing skills in health education, the nurse often needs to learn new behaviors. A systematic guide can be used to learn these professional skills. To perform these steps, the nurse does the following:

- Seeks self-assessment opportunities.
- Identifies, lists, and prioritizes learning needs.
- Begins to identify the resources that are available for reading, instructor training, and practice teaching.
- Drafts an initial set of learning goals.
- Selects the target population and the general topic.
- Works through the steps of the teaching-learning process, including the development of a teaching plan.
- Identifies other people or a project team to help.

After implementing the educational intervention, the nurse sets time aside to discuss what happened. Did the program go as planned? What changes were made in the teaching plan? What can be changed for the next program? The nurse reviews the self-developed learning goals and determines new ones.

In addition, health-education research evaluates teaching interventions. This contributes to the evidence base from which nurses can implement new teaching strategies or question the effectiveness of traditional approaches. For an example of a study comparing the effects of using narrative information versus traditional information to teach a high-risk group, see Box 10-8: Research for Evidence-Based Practice.

Box 10-8

Research for Evidence-Based Practice

Promoting Health Among Teens Intervention

Because black Americans are disproportionately affected by cardiovascular disease and cancer, this health-promotion intervention targeted black American youth to address behaviors that contribute to these disparities in adults. Promoting Health Among Teens (PHAT) is a brief, culturally tailored health-education curriculum focused on dietary behaviors, physical activity, and substance use knowledge in black American teens.

A total of 1654 teens aged 14 to 17 years participated, with at least 400 from each of four mid-sized eastern cities in the United States (Macon, Georgia; Providence, Rhode Island; Syracuse, New York; and Columbia, South Carolina). The teens were randomly assigned to either the PHAT group (experimental) or a sexual-health-promotion group (control). Comparison of general health knowledge at the baseline showed no significant difference between the experimental group and the control group.

The PHAT intervention curriculum consisted of eight modules designed to increase health knowledge, develop health behavior skills, change attitudes, increase self-efficacy, explore beliefs about personal health behaviors, and address factors that interfere with healthy behavior related to diet, physical activity, and substance abuse. The program was tailed to promote cultural pride in black American teens. Workshops were held on two consecutive Saturdays for a total of 16 contact hours with 12 to 13 participants per group. Various interactive learning strategies included discussion, games, role playing, and sharing exercises implemented by trained group facilitators. At least half of the trainers were black American to promote racial concordance. The consistency of the curriculum and implementation was maintained across sites throughout the project.

Audio computer-assisted self-interview (ACASI) was used to collect demographic characteristics, and assess knowledge and behaviors. ACASI helps to reduce literacy-related challenges and social desirability in participant response. Data collection occurred at the baseline and at 3, 6, and 12 months after the intervention to measure differences between PHAT participants and the control group in health knowledge, dietary behaviors, physical activity, and

substance use.

PHAT program participants had significantly greater increases in health knowledge than the control group; however, their changes in behavior were modest. Importantly participants retained the higher knowledge at least 1 year after a brief intervention, and those with higher knowledge demonstrated greater behavior change. Recommendations for the future application of PHAT are to continue the emphasis on knowledge building while increasing the number of contact hours and spreading the intervention over several more days to facilitate behavior change. A longer intervention might allow facilitators to develop increased rapport and trust, practice health behaviors, and develop increased self-efficacy to implement and maintain behavior change. Further research is suggested to explore the differences in the impact of increased knowledge on specific risk behaviors.

From Kerr, J. C., Valois, R. F., Farber, N. B., Vanable, P. A., DiClemente, R. J., Salazar, L., et al. (2013). Effects of promoting health among teens on dietary, physical activity, and substance use knowledge and behaviors for African American adolescents. *American Journal of Health Education*, *44*(4), 191–202.

As additional programs on either an individual or a group basis are provided, the nurse will be able to clarify specific instructor teaching and organizing skills that come naturally.

These skills tend to improve a program's effectiveness and enable the logistics to run smoothly. The teacher is first a learner; this is true in health education and any other form of education.

Case Study

Albert

Albert Mitchell is a 36-year-old man who will be traveling to Dubai to give a business presentation in 3 months. Although he has traveled widely in the United States as a consultant, this is his first trip to the Middle East. He requests information regarding immunizations

needed before his trip. Albert states that as he will be in Dubai for only a few days, he is unlikely to contract a disease in such a short time and therefore believes that it is illogical to obtain immunizations. Albert states that he has heard that the side effects of the immunizations might be worse than the diseases they prevent. He is also concerned about leaving his wife at home alone because she is 6 months pregnant.

Reflective Questions

- How would you address Albert's beliefs?
- What learning would be needed in each domain?
- What learning theories would you consider?
- How might his family concerns be addressed?

Care Plan

Preparing a Teaching Plan

***NURSING DIAGNOSIS: Deficient knowledge (specify area)**

Defining Characteristics

- Verbalization of inadequate information or an inadequate recall of information
- Verbalization of misunderstanding or misconception
- Request for information
- Instructions followed inaccurately
- Inadequate performance on a test

- Inadequate demonstration of a skill

Related Factors

- Pathophysiological states
- Sensory deficits
- Memory loss
- Intellectual limitations
- Interfering coping strategies (denial or anxiety)
- Lack of exposure to accurate information
- Lack of motivation to learn
- Inattention
- Cultural or language barriers

Expected Outcomes

- The individual will express an interest in learning.
- The individual will correctly state the information on the specific topic.
- The individual will correctly demonstrate skills needed to practice health-related behavior.
- The individual and the family will explain how to incorporate new information into their lifestyle.
- The individual will modify health behavior on the basis of the acquisition of new knowledge.

- The individual will list resources for more information or support.

Interventions

- Provide accurate and culturally relevant information related to the specific topic.
- Select teaching techniques appropriate to the individual's learning needs.
- Explore the individual's interpretation of the information and its meaning in the context of the person's life.
- Demonstrate and then have the individual practice new skills.
- Assist the person in identifying and implementing alternative strategies when initial choices are not successful.
- Include the family or significant others as appropriate.
- Provide names and telephone numbers of resource people or organizations.

---

*NANDA Nursing Diagnoses—Herdman, T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Of all health professionals, nurses spend the most time in direct contact with individuals; they have many opportunities to recognize a need for knowledge and a readiness to learn new information and behaviors. Nurses often coordinate group programs. The more accurate the analysis of the educational aspects of a health-promotion program and the assessment of characteristics and learning needs of the target audience, the more effective an educational intervention will be in influencing health behaviors.

The principles of health education form a generic basis for implementing a variety of health topics, such as accident prevention and use of first aid, expectant parent education, hypertension education, nutrition and fitness, stress management, substance abuse, sex education, and education in areas including diabetes and arthritis. The two scenarios described in this chapter provide insights into the nurse's role in conducting educational interventions about family planning and prenatal care.

Planning to teach one person is different from planning to teach a group. One-to-one interventions tend to follow a counseling or problem-solving approach. Group interventions can range from guided discussions on concerns that evolve from the group to a more structured learning experience involving presentations, skill practice, and attitude-awareness exercises. The range of health-education strategies provides nurses and all health care professionals with techniques and methods applicable in health service settings, schools, work sites, and other community facilities.

Nutrition Counseling for Health Promotion

Myrtle McCulloch, Staci McIntosh

OBJECTIVES

After completing this chapter, the reader will be able to:

- Evaluate the objectives outlined in *Healthy People 2020* nutrition and food safety issues.
- Analyze the leading diet-related causes of illness and death in the United States and the corresponding nutrients specific to each.
- Summarize and evaluate the rationale behind the recommendations contained in the *Dietary Guidelines for Americans 2015–2020.*
- Compare the number of servings and serving sizes recommended in MyPlate with serving sizes featured currently in the marketplace.
- Analyze US food aid programs for marginalized groups and older adults in the United States.
- Evaluate personal diet intakes over a 24-hour to 48-hour period using SuperTracker (https://www.supertracker.usda.gov) to learn how to plan diets for any stage in the life cycle.

Think About It

This format may be used to evaluate your own nutrition intake as well to obtain a diet history from a care recipient. Use http://www.choosemyplate.gov.

1. *Ask the individual which food from each of the following food groups he or she has consumed in one 24-hour period. Use a set of household measuring utensils (cups and spoons) to make accurate estimations where possible. Start with this question: In the past 24 hours how many foods did you eat*

from each of the following groups?

Grains (*6 ounces*)	**Vegetables (2½ *cups*)**	**Fruits (*2 cups*)**	**Dairy (*3 cups*)**	**Proteins (5½ *ounces*)**	**Oils, Added Sugars (*Use as directed*)**
Whole or refined grains, cereals, pasta, rice	Whole, canned, fresh, frozen, or juice	Whole fruits, fresh, canned, frozen, sauces, juices	Milk, skim or low fat, cheese, yogurt; soy, rice, or almond milks	Meat, poultry, fish, beans, lentils, nuts	Butter, margarine, cream cheese, sour cream, shortening; sugar, candy, syrup, jelly; soda, alcohol

2. *Use the measuring utensils to estimate amounts from each group and insert them in the corresponding boxes. Recommendations for each food group are listed.*

3. *Use this information to obtain the nutrition analysis using SuperTracker (https://www.supertracker.usda.gov) to explain how to improve the diet or make any other changes that may be of benefit.*

4. *Teach yourself and your clients how to convert grams of sugar into teaspoons. Use 5 g is equivalent to 1 teaspoon of sugar. These are close enough to provide a fair deal of accuracy. In 1 cup of a fruit juice (e.g., cranberry juice) you may get 35 g of sugar. This equals 7 teaspoons. Use this same calculation to check the amount of sugar in yogurt, cereals, and baked goods. As most people do not use the metric system, this method will help.*

Nutrition in the United States: Looking Forward From the Past

Classic Vitamin-Deficiency Diseases

Food and nutrition have always been important to health. Until as recently as the 1940s, many nutrient-deficiency diseases, such as rickets, pellagra, scurvy, beriberi, xerophthalmia (eye fails to produce tears), and goiter, were still prevalent in the United States (Carpenter, 2000). Although these conditions still persist in some developing countries, they have virtually disappeared from developed areas of the world. The availability of an abundant food supply, the fortification of some foods with critical nutrients, and the implementation of better methods of determining and increasing the nutrient contents of foods have contributed to the decline of nutrient-deficiency diseases.

The introduction of iodized salt in the 1920s, for example, contributed greatly to elimination of iodine-deficiency goiter as a public health problem. Similarly, beriberi and pellagra disappeared after the discovery that inadequate thiamine and niacin levels respectively contribute to these diseases. Today, nutrient deficiencies are mostly seen as iron and calcium deficits, with osteoporosis and anemia respectively being the most common, as well as malnutrition related to obesity and its related comorbidities. The few cases of protein-energy malnutrition that are listed annually as causes of death generally occur as secondary results of severe illness or injury, premature birth, child neglect, problems of the homebound aged, alcoholism, or some combination of these factors. Although undernutrition still occurs in some groups of people in the United States, including those who are isolated or poor, these once-prevalent diseases of nutritional deficiency have been replaced by diseases of dietary excess and imbalance (Table 11-1).

TABLE 11-1

Health Problems Related to Poor Nutrition

Health Problem[a]	Contributing Lifestyle and Nutrition Practices[b]
Anemia	Diet with inadequate iron, folate, or vitamin B12 intake (depending on type of anemia)
Cancer (breast, cervical, and colon)	Excessive calorie intake, belly fat; low fiber intake
Cirrhosis	Excessive alcohol intake
Constipation	Inadequate fiber or fluid intake; high fat intake; sedentary lifestyle
Dental caries	Excessive, frequent consumption of concentrated sweets or sugar-sweetened beverages; lack of fluoride; poor dental hygiene
Type 2 diabetes	Excessive calorie intake; excessive fat intake (in particular saturated fat, trans fat); sedentary lifestyle
Cardiovascular/heart disease	Excessive calorie intake; excessive fat intake (in particular saturated fat, trans fat); excessive sodium intake, inadequate fiber intake; sedentary lifestyle
Hypertension	Excessive sodium and insufficient potassium intake; excessive calorie intake; possible excess alcohol intake; sedentary lifestyle
Obesity	Excessive calorie intake; excessive fat intake; sedentary lifestyle
Osteoporosis	Low calcium intake; low vitamin D intake; excessive intake of protein, sodium, and caffeine; sedentary lifestyle; excessive alcohol intake
Underweight and growth failure	Inadequate calorie intake; poor diet

[a]A number of health problems are caused or exacerbated by poor nutrition. Health care professionals strive to prevent or delay these health problems.

[b]Not all may apply in every case.

Dietary Inadequacy

Calorie inadequacies can have devastating effects in children in developing countries leading to wasting and stunting syndromes. Although not to the same degree, many impoverished areas in the United States show some degree of these imbalances.

Although there are differences as to their causes, eating disorders are also classified as calorie imbalances. These can be seen in any sex and age group, with some starting in elementary school children. For diagnostic purposes, there are four conditions: anorexia nervosa, bulimia nervosa, binge eating disorder, and disordered eating not otherwise specified. The latter may include binge eating, compulsive overeating, or overexercising with respect to the calories consumed.

Depending on the length of time and the age of the individual, the physiological consequences, especially for anorexia nervosa, are life threatening. Long-term complications may include alterations in the

heart rate and blood pressure, depletion of lean mass, anemia, bone loss, amenorrhea, hypoglycemia, and psychological symptoms. Early diagnosis and treatment are critical to the success of recovery.

Dietary Excesses

Problems resulting from dietary imbalances (i.e., overconsumption of some foods groups and inadequate consumption of other food groups) now rank among the leading causes of illness and death in the United States. As stated in 2015 by the US Department of Health and Human Services (USDHHS) and the US Department of Agriculture (USDA) in their *Dietary Guidelines for Americans 2015–2020* (USDHHS & USDA, 2015), "the US population, across almost every age and sex group, consumes eating patterns that are low in vegetables, fruits, whole grains, dairy, seafood, and oil and high in refined grains, added sugars, saturated fats, sodium, and for some age-sex groups, high in the meats, poultry, and eggs subgroup."

Four leading causes of death directly associated with diet are **coronary heart disease** (CHD), some types of **cancer, stroke,** and **diabetes mellitus** (DM). Four other major causes of death—accidents, **cirrhosis**, suicide, and homicide—are often associated with excessive alcohol intake.

Current statistics show that two in three American adults and one in three children are either **overweight** or **obese** (Flegal et al., 2010). Although adult levels of overweight/obesity on their own are alarming, excess weight among the young has been linked to health problems that until now were seen only in adults: high blood pressure, type 2 diabetes, and high cholesterol levels (White House Task Force on Childhood Obesity, 2010). Although there has been a slight leveling off as compared with earlier statistics (National Center for Health Statistics, 2010), the proportion of American children who are obese is currently 17% (Ogden et al., 2014).

Reducing the incidence of obesity in any age group is vital to overall health. Although excess weight or obesity is commonly viewed as an imbalance between energy intake and energy expenditure, other factors need to be considered, such as the

environment, race, and socioeconomic status. For example, genes are involved in the process of energy balance as well as in differences in fat distribution by sex and age (Bray & Champagne, 2007). The more recent interest in the human **microbiome** has generated studies on microbial gut alterations, obesity (Kaplanm & Walker, 2012), and diabetes (Tai et al., 2015).

The fifth guideline of the ***Dietary Guidelines for Americans*** *2015–2020* states: "Support healthy eating patterns for all: Everyone has a role in helping to create and support healthy eating patterns in multiple settings nationwide, from home to school to work to communities." The guidelines acknowledge the importance of a coordinated, system-wide approach that engages all sectors of influence. Figure 11-1 demonstrates the complex layers of influence that shape a person's food and physical activity choices. Creating and supporting a healthy eating pattern means that such influential factors have been taken into consideration and that healthy food options should be made available and should be accessible to all individuals. In support of this guideline, the Centers for Disease Control and Prevention (CDC) has proposed strategies for both providing healthy food and preventing obesity in the United States (see Box 11-1: Innovative Practice for examples).

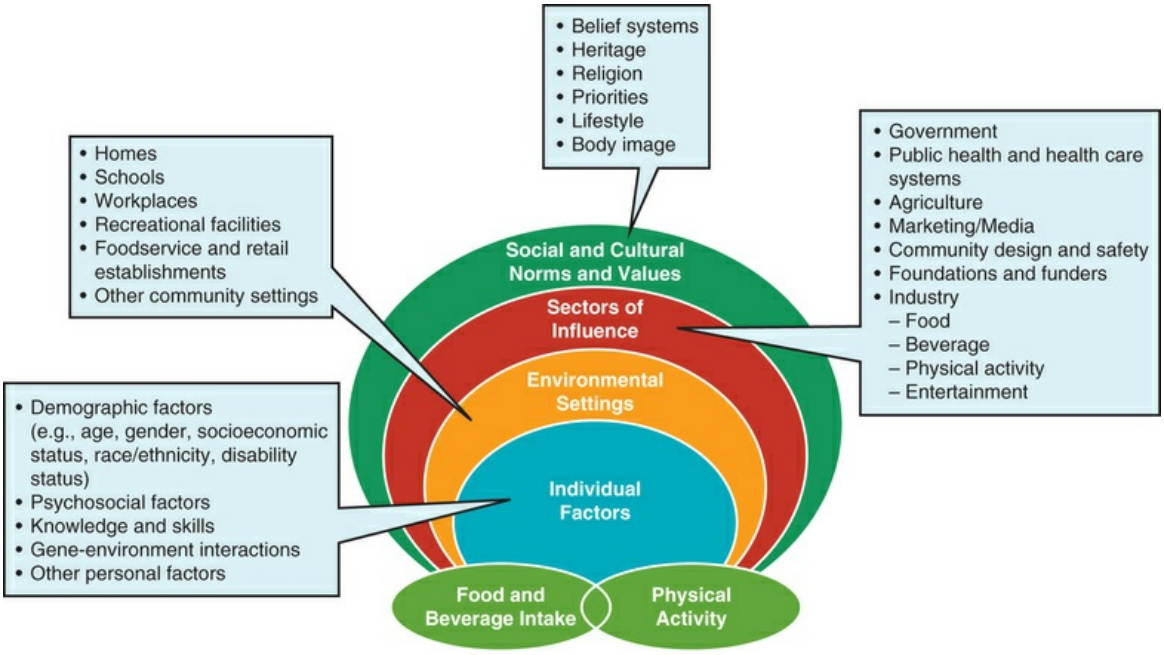

FIGURE 11-1 Social-ecological framework for food and physical activity decisions. (From US Department of Health and Human Services & US Department of Agriculture. [2015]. *Dietary guidelines for Americans 2015–2020* [8th ed.]. http://health.gov/dietaryguidelines/2015/guidelines/.)

Box 11-1

Innovative Practice

Summary of Recommended Community Strategies and Measurements to Prevent Obesity in the United States Related to Healthy Foods[a]

Strategy 1

Communities should increase availability of healthier food and beverage choices in public service venues.

Suggested Measurement

A policy exists to apply nutrition standards that are consistent with the *Dietary Guidelines for Americans* to all food sold (e.g., meal menus

and vending machines) within local government facilities in a local jurisdiction or on public school campuses during the school day within the largest school district in a local jurisdiction.

Strategy 2

Communities should increase availability of affordable healthier food and beverage choices in public service venues.

Suggested Measurement

A policy exists to affect the cost of healthier foods and beverages as defined by the Institute of Medicine (Koplan et al., 2005) relative to the cost of less healthy foods and beverages sold within local government facilities in a local jurisdiction or on public school campuses during the school day within the largest school district in a local jurisdiction.

Strategy 3

Communities should increase geographical availability of supermarkets in underserved areas.

Suggested Measurement

The number of full-service grocery stores and supermarkets per 10,000 residents located within the three largest underserved census tracts within a local jurisdiction.

Strategy 4

Communities should provide incentives to food retailers to locate in and/or offer healthier food and beverage choices in underserved areas.

Suggested Measurement

Local government offers at least one incentive to new and/or existing food retailers to offer healthier food and beverage choices in underserved areas.

Strategy 5

Communities should increase availability of mechanisms for purchasing foods from farms.

Suggested Measurement

The total annual number of farmer-days at farmers' markets per 10,000 residents within a local jurisdiction.

Strategy 6

Communities should provide incentives for the production, distribution, and procurement of foods from local farms.

Suggested Measurement

Local government has a policy that encourages the production, distribution, or procurement of food from local farms in the local jurisdiction.

Strategies to Support Healthy Food and Beverage Choices

Strategy 7

Communities should restrict availability of less healthy foods and beverages in public service venues.

Suggested Measurement

A policy exists that prohibits the sale of less healthy foods and beverages (as defined by the IOM; Koplan et al., 2005) within local government facilities in a local jurisdiction or on public school campuses during the school day within the largest school district in a local jurisdiction.

Strategy 8

Communities should institute smaller portion size options in public service venues.

Suggested Measurement

Local government has a policy to limit the portion size of any entree (including sandwiches and entree salads) by either reducing the standard portion size of entrees or offering smaller portion sizes in

addition to standard portion sizes within local government facilities within a local jurisdiction.

Strategy 9

Communities should limit advertisements of less healthy foods and beverages.

Suggested Measurement

A policy exists that limits advertising and promotion of less healthy foods and beverages within local government facilities in a local jurisdiction or on public school campuses during the school day within the largest school district in a local jurisdiction.

Strategy 10

Communities should discourage consumption of **sugar-**sweetened beverages.

Suggested Measurement

Licensed child care facilities within the local jurisdiction are required to ban sugar-sweetened beverages, including flavored/sweetened milk, and limit the portion size of 100% juice.

Strategy to Encourage Breastfeeding

Strategy 11

Communities should increase support for breastfeeding.

Suggested Measurement

Local government has a policy requiring local government facilities to provide breastfeeding accommodations for employees that include both time and private space for breastfeeding (or pumping of milk) during working hours.

---

[a]The entire report includes 24 strategies and measurements to include those related to physical activity. Because physical activity is discussed in Chapter 12, this excerpt includes nutrition advice only.

Institute of Medicine (IOM), Koplan, J.P., Liverman, C.T., & Kraak, V.I. (2005). *Preventing childhood obesity: Health in the balance*. Washington, DC: The National Academies Press; Khan, L. K., Sobush, K., Keener, D., Goodman, K., Lowry, A., Kakietek, J., et al. (2009). Recommended community strategies and measurements to prevent obesity in the United States. *MMWR. Recommendations and Reports, 58*(EE-7):1-26.

Encouraging healthy choices in diet, exercise, and weight control is also one of the major themes of *Healthy People 2020* (USDHHS, 2010a) (Figure 11-2). It also includes a new framework to include additional emphasis on health disparities and health inequities, as well as focus on future measures to help healthy choices be the easy choice wherever people live, work, learn, and play.

FIGURE 11-2 Children who eat with each other in an appropriate environment often eat more nutritiously and try a wider variety of foods than when eating alone or at home (From Mahan, L. K., & Raymond, J. L. [2017]. *Krause's food & the nutrition care process* [14th ed.]. St Louis: Elsevier.)

Because dietary factors contribute substantially to the burden of preventable illness and premature death, *Healthy People 2020* aims at directing American dietary patterns toward current recommendations, especially the *Dietary Guidelines for Americans 2015–2020* (USDHHS & USDA, 2015).

Healthy People 2020: Nutrition Objectives

The nutrition and weight status objectives of *Healthy People 2020* (Box 11-2: *Healthy People 2020*) reflect evidence-based science supporting the health benefits of consuming a nutritious diet and maintaining a healthy body weight. The objectives also emphasize that efforts to change diet and weight should address individual behaviors, as well as policies and environments that support these behaviors, in settings such as schools, work sites, health care organizations, and communities.

Box 11-2

Healthy People 2020

Objectives Related to Nutrition and Food Safety, Healthier Food Access

- Increase the number of states with nutrition standards for foods and beverages provided to preschool children in child care.
- Increase the proportion of schools that offer nutritious foods and beverages outside school meals.
- Increase the number of states that have state-level policies that incentivize food retail outlets to provide foods that are encouraged by the *Dietary Guidelines for Americans.*
- (Developmental objective) Increase the proportion of Americans who have access to a food retail outlet that sells a variety of foods that are encouraged by the *Dietary Guidelines for Americans.*

Health Care and Work Site Settings

- Increase the proportion of primary care physicians who regularly measure the BMI of their care recipients (both adults and children/adolescents).
- Increase the proportion of physician office visits that include counseling or education related to nutrition or weight (by diagnosis such as CVD, diabetes, hyperlipidemia, or obesity).
- (Developmental objective) Increase the proportion of work sites that offer nutrition or weight-management classes or counseling.

Weight Status

- Increase the proportion of adults who are at a healthy weight.
- (Developmental objective) Prevent inappropriate weight gain in youth and adults.

Food Insecurity

- Eliminate very low food security among children.
- Reduce household food insecurity and in so doing reduce hunger.

Food and Nutrient Consumption

- Increase the contribution of fruits to the diets of the population aged 2 years and older.
- (Leading health indicator) Increase the variety of vegetables in and their contribution to the diets of the population aged 2 years or older (increase the contribution of total vegetables, including dark green vegetables, orange vegetables, and legumes).
- Increase the contribution of whole grains in the diets of the population aged 2 years or older.

- Reduce the consumption of calories from solid fats and added sugars in the population aged 2 years or older.
- Reduce the consumption of saturated fat in the population aged 2 years or older.
- Reduce the consumption of sodium in the population aged 2 years or older.
- Increase the consumption of calcium in the population aged 2 years or older.
- Reduce iron deficiency among young children and females of childbearing age (children aged 1–2 years and aged 3–4 years, females aged 12–49 years).
- Reduce iron deficiency among pregnant females.

Objectives for Selected Diseases With Nutrition Components

Heart Disease and Stroke

Goal: Increase overall cardiovascular health in the US population and reduce CHD and stroke deaths.

- Reduce the proportion of adults with high total blood cholesterol levels.
- Reduce the mean total blood cholesterol levels among adults (for adults aged 20 years or older).
- Increase the proportion of adults with pre-hypertension who meet the recommended guidelines (for nutrition, BMI, saturated fat consumption, sodium intake, and moderate alcohol consumption).
- (Developmental objective) Increase the proportion of adults with hypertension who meet the recommended guidelines (for nutrition,

BMI, saturated fat consumption, sodium intake, and moderate alcohol consumption).

- (Developmental objective) Increase the proportion of adults with elevated LDL cholesterol levels who have been advised by a health care provider regarding cholesterol-lowering management including lifestyle changes (such as cholesterol-lowering diet, weight control) and, if indicated, medication.

- (Developmental objective) Increase the proportion of adults with elevated LDL cholesterol levels who adhere to the prescribed LDL cholesterol–lowering management lifestyle changes (such as cholesterol-lowering diet, weight control) and, if indicated, medication.

- (Developmental objective) Increase the proportion of adults with CHD or stroke who have their LDL cholesterol level at or below recommended levels.

Obesity

- (Leading health indicator) Reduce the proportion of adults who are obese (to 30.6% from 34%).

- (Leading health indicator) Reduce the proportion of children and adolescents (age categories 2–5 years, 6–11 years, 12–19 years) who are considered obese (to 14.6% from almost 17%).

Diabetes

- Improve glycemic control among the population with diagnosed diabetes.

- Improve lipid control among people with diagnosed diabetes.

- Increase the proportion of the population with diagnosed diabetes

whose blood pressure is under control.

- Increase the proportion of people with diabetes who receive formal diabetes education.

- Increase prevention behaviors in people with pre-diabetes at high risk of diabetes.

Objectives for Food Safety

- Reduce the number of outbreak-associated infections due to Shiga toxin–producing *E. coli* O157, or *Campylobacter, Listeria,* or *Salmonella* species associated with food commodity groups (beef, dairy, fruits and nuts, leafy vegetables, and poultry).

Key Food Safety Practices

- Increase the proportion of consumers who follow key food safety practices (clean: wash hands and surfaces often; separate: do not cross-contaminate; cook: cook to proper temperatures; chill: refrigerate promptly).

- (Developmental) Improve food safety practices associated with food-borne illness in food service and retail establishments.

From US Department of Health and Human Services. (2010). *Healthy People 2020.* Washington, DC: US Government Printing Office. http://www.healhypeople.gov/2020/default.aspx.

The report also contains 12 topics of leading health indicators, with "Nutrition, Physical Activity, and Obesity" being one of them. Although the importance of physical activity will be discussed in Chapter 12, combining physical activity with nutrition and obesity as one topic illustrates how interrelated they are. Details of the leading nutrition health indicators are listed in Box 11-2: *Healthy People 2020*.

Nutrition-Related Health Status

A variety of diet-related factors exact a heavy toll on the US population as the following key points illustrate (CDC, 2015; Food Research and Action Center [FRAC], 2011; National Prevention Council, 2011). The following statements give a broad-based view of the health status of Americans:

- Less than 18% of adults in each state surveyed consumed the recommended amount of fruit, and less than 14% consumed the recommended amount of vegetables (CDC, 2015).
- From 2007 to 2010, 60% of children consumed fewer cup equivalents of fruit than recommended, and 93% consumed fewer vegetables than recommended.
- Sixty-three percent of adults and 84% of adolescents consume at least one sugar-sweetened drink (e.g., soda, sport drinks, fruit drinks and punches, low-calorie drinks, sweetened tea) each day.
- Most American adults consume more than twice the recommended average daily sodium intake level (for healthy people). Nearly 80% of this sodium originates from packaged, processed, and restaurant foods.
- More than two-thirds of the adult population is overweight or obese. Approximately one in five children are overweight or obese by the time they reach age 6 years, and more than half of obese children become overweight at or before age 2 years.
- Low-income women are more likely than their higher-income counterparts to return to work earlier after childbirth and to be engaged in jobs that make it challenging for them to breastfeed. Babies who are breastfed may be less likely to become obese (USDHHS, 2011).
- Almost 50 million households (15%) experience **food insecurity** at least occasionally during the year, meaning that their access to adequate food is limited by a lack of money and other resources. Individuals and families who experience food insecurity may be more likely to be overweight or obese, potentially because of the relatively lower cost of calorie-dense foods (i.e., foods with a low nutrient density).

- Each year approximately one in six Americans (48 million people) become ill. Of those who are sick, 128,000 are hospitalized and 3000 die of food-borne diseases. Reducing the number of people affected by food-borne illness by 10% would prevent illness in approximately 5 million Americans each year.

Nutrition Objectives for the United States

As can be seen already, a considerable gap exists between public health recommendations and consumer practices. The overarching goal for nutrition in the second decade of the millennium is that food intake patterns change in the direction of the targeted goals recommended in *Healthy People 2020,* the *Dietary Guidelines for Americans 2015–2020,* and the **MyPlate** food guidance system.

Food and Nutrition Recommendations

Food and nutrition guidelines are introduced in this chapter, with the intent of motivating the reader to achieve three principal goals. The first goal is to encourage individual interest in the health-promoting power of good nutrition and to promote self-evaluation and comparison of one's own food habits and choices with respect to the dietary recommendations presented here. The second goal is to understand the many systemic factors that have contributed to the current nutrition-related health issues. These problems are so pervasive that many health authorities believe a multisectoral approach, beyond traditional education about healthy food choices, is required. A final goal is to define the kinds and amounts of food that are generally acknowledged as essential for obtaining the necessary energy and nutrients required for health. The following reports provide the foundation for national nutrition recommendations that have been translated into law, policy, programs, and many consumer messages.

- *Dietary Reference Intakes*: *The Essential Guide to Nutrient Requirements* (National Research Council, 2006) and *Dietary Reference Intakes for Calcium and Vitamin D* (National Research Council, 2010)
- *Dietary Guidelines for Americans 2015–2020*, eighth edition (USDHHS & USDA, 2015)
- MyPlate food guidance system (USDA, Center for Nutrition Policy and Promotion, 2010) (Figure 11-3)

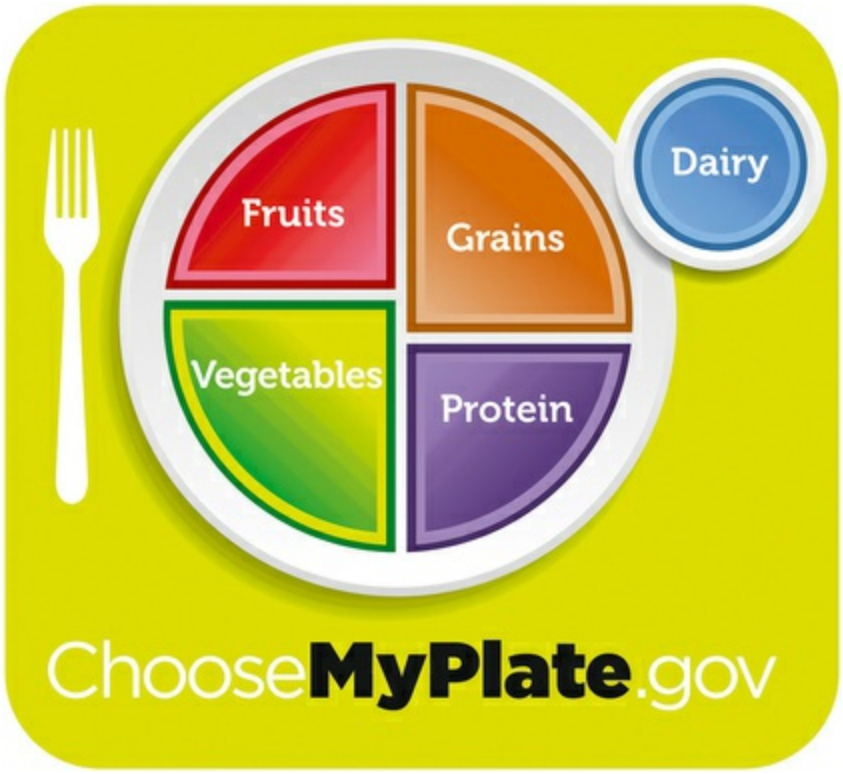

FIGURE 11-3 Learn about healthy eating at http://www.choosemyplate.gov. (From US Department of Agriculture, Center for Nutrition Policy and Promotion. [n.d.]. *Choose MyPlate.* http://www.choosemyplate.gov.)

Dietary Reference Intakes

The original **dietary reference intakes** (DRIs) were developed by the Institute of Medicine (IOM) of the National Academies of Sciences, Engineering, and Medicine in 1997 to reflect the latest understanding about nutrient requirements based on optimizing health in individuals and groups. They are quantitative estimates of nutrient intakes, which can be used to plan and assess the diets of healthy people in the United States, to prevent disease and deficiencies. The recommended dietary allowances (RDAs) form the basis for the DRIs. The adequate intakes are to be used whenever there is not enough evidence to include a nutrient in the RDAs. See Box 11-3: Dietary Reference Intake Components and Definitions for details on these components and suggested uses.

Box 11-3

Dietary Reference Intake Components and Definitions

Estimated Average Requirement

Estimated average requirement (EAR) is the (median) intake that meets the estimated nutrient needs of half of the individuals in a particular life stage and gender group. It is used as a basis for developing the RDA and is especially useful for evaluating adequacy of nutrient intake of a group (or groups) and for planning how much the group(s) should consume.

Recommended Dietary Allowance

RDA is the average dietary intake level that is sufficient to meet the nutrient requirement of nearly all (97–98%) healthy individuals in a particular life stage and gender group. It is computed with use of the EAR. In the past, the RDA of most nutrients represented the levels needed to prevent deficiency diseases. Now an RDA also includes the goal of preventing chronic diseases (e.g., heart disease or osteoporosis, where applicable). As a variety of IOM DRI publications note, the RDA should not be used to assess or plan nutrient intake for groups but may be useful in some individual applications (Taylor, 2008).

Adequate Intake

An adequate intake (AI) is set to fill the gap (e.g., infants) when there is not enough scientific evidence to determine the RDA. The AI is based on estimates of observed or experimentally determined mean nutrient intake of a group (or groups) of healthy people and assumes that the amount consumed is adequate to promote health. The level is set to meet or exceed the needs of almost all people in a particular life stage and gender group. This is the most controversial component in the DRIs.

Tolerable Upper Intake Level

This is the highest average daily intake that can be safely eaten continuously and still be considered safe for almost all healthy individuals in a specified group. The UL is not intended to be a recommended level of intake. No established benefit exists for individuals to consume nutrients at levels above the RDA or AI. As intake increases above the UL, the potential risk of adverse health effects increases. For most nutrients the UL would include total intakes from any of the following (alone or in combination): food, fortified food, and nutrient supplements. It is important to note that ULs are set only when there is a strong pool of scientific data. In cases where the evidence is limited or inconclusive, a UL will not be established. In that case, eating levels close to the RDA or AI (as applicable) is not advised.

Acceptable Macronutrient Distribution Range

This is the range of intake for a particular energy source (e.g., carbohydrate, fat, and protein) that is associated with reduced risk of chronic disease while providing intakes of essential nutrients for a healthy person within an identified life stage and gender group. An intake outside the acceptable macronutrient distribution range (AMDR) carries the potential of increased risk of chronic diseases and/or insufficient intakes of essential nutrients. For example, the AMDR for carbohydrates for a 19-year-old woman (in the life stage and gender group of female, 19–30 yrs old) is 45% to 65% of calories.

Estimated Energy Requirement

This is the average dietary energy intake predicted to maintain energy balance in a healthy adult of a specific life stage and gender group calculated with a reference weight, height, and level of physical activity that is consistent with good health.

From the American Dietetic Association Evidence Analysis Library and based on Greer, N., Mosser, G., Logan, G., & Wagstrom Halaas, G. (2000). A practical approach to evidence grading. *The Joint Commission Journal on Quality Improvement, 26*, 700–712; Taylor, C. L. (2008). *Framework for DRI development: Components "known" and components "to be explored."*

Background paper. Washington, DC: Institute of Medicine, National Academies of Science, Engineering and Medicine. http://www.nationalacademies.org/hmd/Activities/Nutrition/SummaryDRIs/~/media/Files/Ac
US Department of Agriculture. (2010). Appendix 16: Glossary of terms. In *Dietary guidelines for Americans* (7th ed.). Washington, DC: US Government Printing Office. http://www.cnpp.usda.gov/Publications/DietaryGuidelines/2010/PolicyDoc/PolicyDoc.pdf.

It is important to note that in contrast to the routine 5-year review of the *Dietary Guidelines for Americans,* the DRIs are updated only when deemed necessary. In 2008 the US and Canadian governments decided there were enough new studies as well as concern about vitamin D, in particular, to warrant the development of new DRIs for vitamin D and calcium. The latest updates were published in late 2010. The revision of the vitamin D and calcium DRIs since 1997 demonstrates that DRIs continue to be researched and revised as more information and evidence-based studies become available.

There are some controversies over DRIs because there may be limited data relating to genetic diversity in the population or specific groups such as children, pregnant women, and elderly people. However, they are a good starting point based on best available evidence and probability of harm or benefit.

As the DRIs are intended to be applied to healthy people, it is possible that a provider might override the DRI for a specific nutrient on the basis of clinical judgment and recommend more or less for a particular recipient. It is also helpful to remember that whereas DRIs may be used for individuals, ideally, they are guidelines for population groups and apply over time. So, if an individual does not meet the recommendation for a specific nutrient, such as vitamin C, on a certain day, that is not a cause for alarm. It is the trend that matters with respect to food sources as opposed to supplements.

After this discussion of DRIs, the twentieth-century anthropologist Margaret Mead's statement that “People eat food, not nutrition” seems particularly apt. Nutrition recommendations stated in terms of micrograms or milligrams of nutrients are of no use unless people are advised as to what types and quantities of foods should be consumed to meet the recommendations. The intent of *Dietary Guidelines for Americans 2015–2020* has been to translate science-based nutrition

recommendations into optimal eating guidelines that can be adopted by the public to maximize healthy habits and minimize chronic disease.

The DRIs also form the foundation for US nutrition policy, in the design and implementation of nutrition-related programs, including federal nutrition programs for families, children, and elderly people. These guidelines also provide nutrition education initiatives for the general public of adults and children aged 2 years or older.

Dietary Guidelines for Americans 2015–2020

Key recommendations from the 2015–2020 **Dietary Guidelines Advisory Committee** (DGAC) include recommendations to:

- Follow a healthy eating pattern across the life span. All food and beverage choices matter. Choose a healthy eating pattern at an appropriate calorie level to help achieve and maintain a healthy body weight, support nutrient adequacy, and reduce the risk of chronic disease.
- Focus on variety, nutrient density, and amount. To meet nutrient needs within calorie limits, choose a variety of nutrient-dense foods across and within all food groups in recommended amounts.
- Limit calories from added sugars and saturated fats and reduce sodium intake. Consume an eating pattern low in added sugars, saturated fats, and sodium. Cut back on foods and beverages higher in these components to amounts that fit within healthy eating patterns.
- Shift to healthier food and beverage choices. Choose nutrient-dense foods and beverages across and within all food groups in place of less healthy choices. Consider cultural and personal preferences to make these shifts easier to accomplish and maintain.
- Support healthy eating patterns for all. Everyone has a role in helping to create and support healthy eating patterns in multiple settings nationwide, from home to school to work to communities.

Other topics addressed in detail include guidance for specific

population groups: children and adolescents, women of childbearing age, pregnant and breastfeeding women, and older adults, as well as adults at high risk of chronic disease. A discussion of how to build healthy eating patterns embraces USDA eating patterns with **lacto-ovo vegetarian, vegan,** and **Dietary Approaches to Stop Hypertension (DASH)** variations provided at various calorie levels. (For details, see http://health.gov/dietaryguidelines/.) For nursing professionals interested in helping themselves or others balance calories, Chapter 2 is particularly helpful. Just like *Healthy People 2020,* the report includes an emphasis on consumer aspects of food safety.

Representing the best and most current scientific evidence and advice from nutrition experts, these guidelines are intended to reduce the nation's major diet-related health problems such as CHD, certain cancers, diabetes, high blood pressure, obesity, **osteoporosis,** and stroke (USDA, Food and Nutrition Service [FNS], 2011c).

Nursing professionals play a key role in promoting the *Dietary Guidelines of Americans* as one component of healthful lifestyles. For more information about the articles and reports used to inform the development of the *Dietary Guidelines for Americans,* see the *Report of the Dietary Guidelines Advisory Committee* on the *Dietary Guidelines for Americans 2015–2020,* and the related USDA's Nutrition Evidence Library website (http://www.nel.gov/) (USDA, 2015).

The latest MyPlate food icon revision has retained the on-line tracker tools (now called SuperTracker for adults and BlastOff for kids) as well as Spanish language versions of educational materials.

The USDA unveiled MyPlate in June 2011 in keeping with the 2010 White House Child Obesity Task Force's call for action to provide the US public with easy to understand and useful advice. MyPlate visually reminds consumers what a healthy “plate” looks like using a familiar place setting (see Figure 11-3). It is not meant to stand alone as a teaching tool. Consumers and health professionals are directed to the website (http://www.choosemyplate.gov) for details. The new food guidance system puts four of the food groups on the plate (grains, vegetables, fruits, and protein group [which replaced the meat and bean group]) with dairy (including milk and dairy substitutes) on

the side.

Although the USDA's MyPlate food guidance system reflects general eating patterns of Americans, it has enough flexibility for different cultural traditions and eating patterns, including vegetarian (see Box 11-4: Diversity Awareness).

Box 11-4

Diversity Awareness

Food and Culture

The reasons why people eat the ways they do are numerous. Although it is true that without food people cannot survive, food is much more than a tool of survival. Food is also a source of pleasure ("Let's eat out tonight"), a source of comfort ("Right now, I could use some of my mother's chicken soup"), a symbol of hospitality ("Please come to my house for brunch on Sunday"), and an indicator of social status (consider an expensive T-bone steak versus a hamburger). Food also has ritual significance. Drinking champagne to celebrate an important event, the bride and groom saving the top layer of their wedding cake, and people of the Jewish faith sharing challah (braided bread) at their Sabbath (Friday evening) meal are examples.

To a large extent the environment determines what people typically eat. For example, wheat that is plentiful in the heartland of the United States is the principal grain in North America, whereas rice enjoys a similar status in Asian countries. Typical wheat-based staples in the United States and Canada include a slice of wheat bread, a bowl of wheat cereal, wheat crackers, pastries made from wheat flour, and pasta made from wheat. Rice-based foods form the backbone of the Chinese diet.

Every culture has its particular food ways, or activities related to food. Food ways include the activities that surround procuring, distributing, storing, consuming, and disposing of food, all of which define what is fit to eat, or what is edible. Factors that affect everyone's food choices and factors that affect food selections of new

arrivals to a community should be examined. It is important to remember, however, that just because a person is from a specific culture does not mean the person follows his or her cultural food patterns. These general guidelines are helpful as a starting point, but do not assume—ask questions to clarify specific eating habits with individuals and families.

Among traditional Chinese people, health and disease are believed to relate to the balance between the forces of yin and yang in the body. Diseases that are caused by yang forces may be treated with yin forces to restore balance. Yin foods include low-calorie-density, low-protein foods, such as fresh fruits and vegetables. Yang foods are high in calories, cooked in oil, and irritating to the mouth, or are red, orange, or yellow. Examples include most meats, chili peppers, tomatoes, garlic, ginger, and alcoholic beverages. The hot-cold theory in Puerto Rico follows the same basic principles as do yin and yang, but the food groupings differ somewhat.

Religious beliefs affect the food choices of millions of people worldwide. Many religions, including Buddhism, Hinduism, Islam, Judaism, and Seventh Day Adventism, specify the foods that may be eaten and how they should be prepared. The following is a very basic summary of the principal dietary practices of these five major world religions (adapted from Barer-Stein, 1979, and Kittler & Sucher, 2000).

Many Buddhists practice vegetarianism. Foods of plant origin are viewed as the most appropriate for consumption, except pungent foods (garlic, leeks, scallions, chives, and onions), which are believed to generate lust when eaten cooked and to cause rage when eaten raw. For most Buddhists, however, dietary rules such as these are observed on a voluntary basis. What characterizes all Buddhists is the belief that all forms of life share a common link and are thus sacred. Therefore rather than the specific type of food eaten, more important is the attitude of the person receiving the food and the person's sincere gratitude for the lives of the plants and animals contained in the meal that have served to sustain and further enhance the life of the individual.

Many Hindus practice vegetarianism, but those who originate from

the cold northern areas of India usually eat meat (except for beef, which is considered sacred and prohibited).

Many Muslims follow Islamic food laws, which include foods that are halal (permitted), haram (prohibited), and questionable (*mashbooh*). Foods believed to be unclean, or haram, are animals that are improperly slaughtered or already-dead animals such as carrion, swine/pork and its by-products (bacon, lard, shortening), carnivorous animals with fangs (dogs, cats, and lions), birds of prey, and land animals without ears (frogs and snakes). Alcohol and intoxicants are also prohibited. Halal-certified products are used.

Conservative Jews follow Judaic food laws, which prohibit the consumption of swine/pork, carrion, carrion eaters (scavengers), shellfish, animals with a cloven (split) hoof and that do not chew their cud (horses), and animals not slaughtered by the appropriate ritual method or kosher (fit). According to Jewish kosher dietary laws, meat (beef, lamb, veal, and poultry), fish, and meat products (eggs) cannot be served at the same meal or be cooked or eaten in the same vessels as dairy products. Kosher-certified products are used.

The dietary practices of Seventh Day Adventists focus on health, so many Seventh Day Adventists practice vegetarianism as the foundation of their dietary standard. They also abstain from alcohol, and many do not drink caffeine-containing beverages.

From Barer-Stein, T. (1979). Multiculturalism and nutrition counseling. *Journal of the Canadian Dietetic Association*, *40*(2), 112–116; Kittler, P. G., & Sucher, K. P. (2000). *Cultural foods: Traditions and trends.* Belmont, CA: Wadsworth.

Recognizing that in recent years almost 15 million adults and children have found it difficult to obtain enough food to meet their needs, the MyPlate website includes an emphasis on resources for eating on a budget and how to access nutrition assistance programs. The USDA also has resources available in Spanish. The website continues to be updated, so it is worth checking periodically.

Dietary Supplements and Herbal Medicines

In recent decades the popularity of supplemental vitamins, minerals, proteins, **fiber,** and herbs has earned a high profile in the health field. It was the explosion of the use of single-component dietary supplements in the 1980s that helped to spur the change from the old RDAs to the DRIs. New evidence indicated that perhaps ranges of nutrients could be used that were higher than the old "one size fits all" RDAs. At the same time, there appeared to be a point at which a nutrient could pose more of a risk than an advantage. As a result, tolerable upper limit (UL) guidelines were developed for specific life stages, ages, and gender (Taylor, 2008).

According to the National Institutes of Health (NIH), Office of Dietary Supplements (2012), most US adults take one or more dietary supplements either daily or occasionally. Almost 18% take other products, such as fish oil, echinacea, flaxseed oil, and ginseng (National Center for Complementary and Alternative Medicine, 2010). The 1994 Dietary Supplement Health and Education Act expanded the definition of dietary supplement to include any product intended for ingestion as a supplement to the diet. Today's dietary supplements include vitamins, minerals, **herbals** and **botanicals,** amino acids, enzymes, probiotics, and fish oils, as well as powders, energy drinks, and energy bars. People use supplements as if they were drugs. Additionally, they are marketed in the same manner as over-the-counter medications. To distinguish a dietary supplement from an over-the-counter drug, the words *dietary supplement* must appear on the product label. The labels may carry certain types of structure-function claims about certain common conditions associated with aging, pregnancy, menopause, and adolescence that do not relate to disease. These include health maintenance claims ("maintains a healthy circulatory system"), other nondisease claims ("for muscle enhancement" or "helps you relax"), and claims for common, minor

symptoms associated with life stages ("for common symptoms of premenstrual syndrome" or "for hot flashes"). Such claims must be followed by the words "This statement has not been evaluated by the Food and Drug Administration. This product is not intended to diagnose, treat, cure, or prevent any disease." (Food and Drug Administration [FDA], 2008).

Because the FDA is the federal agency that oversees both dietary supplements and drugs, it might be easy to assume the federal regulations for supplements and drugs are similar. This is not the case. Dietary supplements are not regulated by the FDA in the sense that they do not require premarket review or approval by the FDA. Although a supplement manufacturer is responsible for providing evidence that its products are safe and its label claims are truthful and not misleading, it does not have to provide that evidence to the FDA before marketing the product.

Once a dietary supplement is on the market, the FDA monitors information on the product label and package insert to make sure that information about the supplement's content is accurate and that any claims made for the product are truthful and not misleading. If the FDA finds a product to be unsafe or otherwise unfit for human consumption, it may take enforcement action to remove the product from the marketplace or it may work with the manufacturer to voluntarily recall the product. Some supplements have had to be recalled because of proven or potential harmful effects. The reasons for these recalls include microbiological, pesticide, and heavy metal contamination; absence of a dietary ingredient claimed to be in the product; and the presence of more or less than the amount of the dietary ingredient claimed on the label.

The federal government can take legal action against companies and websites that sell dietary supplements when the companies make false or deceptive statements about their products, if they promote them as treatments or cures for diseases, or if their products are unsafe. In a position paper, the Academy of Nutrition and Dietetics (formerly the American Dietetic Association) states that some people may benefit from supplements but that a diet rich in nutrients should

be their major source (Marra & Bovar, 2009). It went further to say that practitioners need to keep up to date on the safety and efficacy of these supplements. Although laws exist to help protect the consumer, the reality is that it is a "buyer beware" environment because of historically low funding and resources for the FDA, along with political pressure and lack of scientific study on the overwhelming majority of supplements available in the United States (Nestle, 2002).

Although the desirable way for the general public to obtain recommended levels of nutrients is by eating a variety of foods, if people take dietary supplements, they should avoid taking them in excess of the UL of the DRI for those nutrients for their age and gender group to preclude possible adverse effects. An example of this is a recent study of the effects of dietary as well as calcium supplementation in fracture prevention in which it was concluded that there was no such association (Bolland et al., 2015). For other types of supplements, such as herbals or botanicals, caution is also advised. Natural is not always better. For example, the National Center for Complementary and Alternative Medicine cautions against the use of products such as comfrey or kava, which can be toxic to the liver.

Vitamin and Mineral Toxicity

Toxic levels of certain **micronutrients** can cause a host of health problems. For example, it is important to advise individuals not to overuse the fat-soluble vitamins (vitamins A, D, E, and K). Of particular concern is vitamin A, an excess of which may be **teratogenic** during pregnancy or may increase the risk of lung cancer for current or former smokers (American Dietetic Association, 2009). On the other hand, water-soluble vitamins such as vitamin C and the B-complex vitamins may pose less danger because the body is able to excrete them through the urine.

Nutrient imbalances and toxicities are rarely likely to occur when nutrients are derived from foods in a normal diet. Most nutrient toxicities occur through supplementation, and in some cases with a combination of supplementation and fortification of foods. The

estimated toxic doses for daily oral consumption of vitamins and minerals by adults are as low as five times the recommended intake for selenium, and as high as 25 to 50 times or more the recommended intakes for folic acid and vitamins C and E. The toxicities of high doses of nutrients such as vitamin A, vitamin B6, vitamin D, niacin, iron, and selenium are well established. Iron supplements intended for other household members are the most common cause of pediatric poisoning deaths in the United States (National Library of Medicine, 2011).

Large doses of vitamin A may be teratogenic. Because of this risk, supplementation with preformed vitamin A should be avoided during the first trimester of pregnancy unless there is evidence of deficiency (see Box 11-5: Quality and Safety Scenario). Excess preformed vitamin A supplements (more than 10,000 international units [IU]) during the first trimester of pregnancy has been linked to birth defects of the eyes, lungs, skull, and heart (Office of Dietary Supplements, 2012). Such a risk in early pregnancy raises the need for caution about general vitamin and mineral supplement use by women of childbearing age.

Box 11-5

Quality And Safety Scenario

Supplements/Vitamin A

Adele is a 32-year-old married black American woman with no children and a history of one miscarriage. She and her husband have been trying to conceive for the past 4 years and have recently started talking about going to a fertility clinic. Always one to try the “natural way” first, she read that vitamin A is important for normal fetal development and decides to take a multivitamin supplement with 25,000 IU of preformed vitamin A. Adele knows that she can get vitamin A from food, but she also makes an effort to read nutrition labels and choose fortified foods that have 20% or more vitamin A content. She comes into the physician's office for a regular routine

visit. It is common knowledge that she and her husband are trying to have a baby.

Reflective Questions

- Why is it important to discuss the use and type of supplements (and potentially fortified food use) during preconception/pregnancy?
- What is the vitamin A DRI recommendation for a woman of her age?
- How can learning about simple changes in her eating habits/supplement use affect her risk of a spontaneous abortion or a birth defect in the event of pregnancy?
- What would your next step be in this situation?

Note: One retinol activity equivalent = 1 mcg of all-*trans*-retinol = 3.33 IU from retinol = 2 mcg of supplemental all-*trans*-β-carotene = 12 mcg of dietary all-*trans*-β-carotene = 24 mcg of other dietary provitamin A carotenoids. *DRI,* Dietary reference intake.

Besides problems with direct toxicity of some individual nutrients, there may be problems related to nutrient imbalances or adverse interactions with prescribed medication. Often, high doses of a single nutrient may reflect interactions that result in a relative deficiency of another nutrient (American Dietetic Association, 2009). Some examples follow:

- High doses of vitamin E can interfere with vitamin K action and enhance the effect of warfarin as one of the anticoagulant drugs. Examples such as this are one of the reasons that health care providers may ask about supplement use before surgery and recommend discontinuation of use of certain supplements for 1 week before and 1 week after surgery. Large amounts of calcium inhibit absorption of iron and possibly other trace elements.
- Folic acid can mask hematological signs of vitamin B12 deficiency,

which, if untreated, can result in irreversible neurological damage. Folic acid can also interact adversely with anticonvulsant medications.

- Zinc supplementation can reduce copper levels, impair immune responses, and decrease levels of high-density lipoprotein (HDL) **cholesterol** ("good" cholesterol).

Nursing professionals can help people who suspect an adverse supplement effect by reporting the event to the FDA, or by encouraging the individual to file a report. This should be done as soon as possible when there is a suspected problem. Information on how to do this is available at http://www.fda.gov/food/dietarysupplements/reportadverseevent/. Another avenue is to alert the product's manufacturer or distributor to any serious side effects through the address or phone number listed on the supplement's label. By law, dietary supplement firms are required to forward reports they receive about serious adverse effects to the FDA within 15 days.

Circumstances When Nutrient Supplementation Is Indicated

Nutrient supplements or fortified foods, or sometimes a combination of both, are sometimes necessary for specific populations to obtain desirable amounts of particular nutrients (National Research Council, 2010; USDHHS & USDA, 2015). Some examples follow:

- Folic acid (400 mcg) from fortified enriched grains or supplements in addition to folate-rich foods for women who could become pregnant to help prevent neural tube defects.
- Iron supplements during pregnancy when indicated in laboratory tests.
- Calcium and vitamin D supplements in older postmenopausal women to reduce their risk of osteoporosis (levels should not exceed the UL of 2000 mg for calcium or 100 mcg for vitamin D through either supplements or a combination of foods and supplements).

- Vitamin D for those who do not meet the recommended DRI intake (without exceeding the DRI UL of 4000 IU or 100 mcg by a combination of food, supplement, and fortified food).
- Vitamin B12 through food fortified with the crystalline form or B12 supplements for individuals older than 50 years (who may often have a reduced ability to absorb naturally occurring vitamin B12). In addition, vegans should ensure they have adequate intake of vitamin B12 through fortified foods or supplements.

People can get their nutritional requirements from foods and, when necessary, from supplements. However, the amounts needed are generalized to population studies (e.g., amounts for all women during pregnancy). These requirements do not account for individual genetic variations. In the future, it may be possible for specific nutrients to be prescribed to individuals on the basis of genomic maps. This new and exciting study of **nutrigenomics** explores the effects of nutrients on gene expression. However, when it comes to nutrients in foods and their effects on gene expression, the science is not ready to create diets specific to an individual's genome makeup. As this is an issue of ethics medicine as well as nutrition, it is a field that will move with caution (Pavlidis et al., 2015).

Food Safety

Americans spend more than $1 trillion on food each year, with nearly 50% of food consumption occurring outside the home (Johnson, 2011). The combined efforts of the food industry and the regulatory agencies are often credited with making the US food supply among the safest in the world. Nonetheless, the CDC reports that each year an estimated one in six Americans—a total of 48 million people—become sick from food-borne illnesses caused by contamination by any of a number of microbial pathogens. Of these, an estimated 128,000 people require hospitalization and 3000 people die (CDC, 2011a). Food-borne illnesses are estimated to cost the United States $77.7 billion annually, not including costs to the food industry or public health agencies.

Attention to food-borne illnesses is becoming increasingly important with the globalization of the world's food supply. New disease-causing organisms have emerged, and food imports from countries without the same safety standards as the United States are on the rise. Furthermore, more consumers are demanding fresh produce and more seafood to be available throughout the year as well as accessibility to less-processed foods, such as raw milk and fresh juices that are not cooked or pasteurized to kill bacteria. Consumers may also ignore warnings about unsafe food habits because of preferences for foods such as raw oysters, rare hamburgers, fresh juices, unpasteurized cheese, and runny egg yolks, which all carry higher risks of contamination.

To protect the public from numerous sources of food contamination (physical, chemical, biological), private industry and numerous federal, state, and local agencies share responsibilities for regulating the safety of the US food supply. On the food industry side, one example of initiatives is food processors that are working on programs to better trace products through the supply chain and monitor temperatures in trucks from remote locations. In late 2010, Congress passed sweeping food safety legislation called the Food Safety Modernization Act (FSMA), which gives the FDA new powers to

police food safety and focus its efforts on preventing food contamination. Subject to adequate funding, the FSMA allows the FDA to increase its inspection of imported food, set safety standards for fresh produce, force companies to recall tainted products, and require companies to keep better production records.

When the safeguards built into this system fail, however, consumers themselves must serve as the final and sometimes most important guardian against unsafe food. Therefore it is essential to be informed and educated about the potential dangers of food-borne illness and ways to avoid contaminated food products.

Causes of Food-Borne Illness

A food-borne illness is classified according to the source of its contamination (the unintended presence of harmful substances or microorganisms). Food contaminants may be categorized as biological, chemical, or physical. Biological contaminants include bacteria, viruses, parasites, and fungi (yeasts and molds). Chemical contamination refers to the presence of pesticides, kitchen-cleaning supplies, and toxic chemicals in food that have been leached from worn metal cookware and equipment. Physical contamination includes dirt, glass chips, crockery, wood, splinters, stones, hair, jewelry, and metal shavings from dull can openers. Another unintended physical contaminant may be an unintended allergen added to a food product that typically does not include that ingredient (such as peanuts) during food processing in the same location.

Examples of Common Food-Borne Pathogens

The safety of the US food supply is so important that there are specific objectives tied to the monitoring of common pathogens in *Healthy People 2020*. These include outbreak-associated infections attributable to Shiga toxin–producing *Escherichia coli* O157, or *Campylobacter*, *Listeria,* or *Salmonella* species associated with food commodity groups (e.g., beef, dairy, fruits and nuts, leafy vegetables, and poultry). Two

common types are discussed next.

Salmonellosis

The most frequently reported cause of food-borne illness is from *Salmonella* bacteria. Each year in the United States, approximately 40,000 cases of **salmonellosis** are reported, with 400 deaths from acute salmonellosis (CDC, 2010). The actual number of infections may be closer to 1.4 million because milder cases are often not diagnosed or reported. Although the *Salmonella* family includes more than 2300 serotypes of the bacterium, the most common in the United States are *Salmonella enteritidis* and *Salmonella typhimurium.*

The typical way humans are exposed to salmonellosis is by consuming foods contaminated with animal feces. Foods of animal origin such as beef, poultry, milk, and eggs are often the source of infection. However, *all* foods, including seafood from polluted water and vegetables, may become contaminated. Contamination may also occur from unsanitary handling of foods and utensils by infected food handlers and contact with the feces of some pets, especially those with diarrhea. Symptoms of salmonellosis (CDC, 2004) include abdominal cramping, mild to severe diarrhea, nausea, vomiting, and fever within 8 to 72 hours after infection. Symptoms may resolve within 4 to 7 days without treatment; however, infections can become life threatening for people with weakened immune systems such as infants with an immature immune system, young children, pregnant women, older adults, and people with autoimmune disorders or those being treated for cancer. Antibiotics are usually not necessary unless the infection spreads from the intestines. To prevent salmonellosis, avoid uncooked egg dishes, undercooked meat, shellfish, and unpasteurized milk and juice. Adherence to sanitary regulations, as well as proper food handling, is necessary to control salmonellosis outbreaks.

Escherichia coli O157:H7 Infection

Theodor Escherichia, a German pediatrician, first discovered the *E. coli* bacterium in the human colon in 1885. A particularly virulent

strain of *E. coli*, known as *E. coli* O157:H7, was first identified in 1982 as a food-borne pathogen during an investigation of an outbreak of severe bloody diarrhea attributable to ingestion of contaminated hamburgers. As a leading cause of food-borne illness, *E. coli* O157:H7 can produce a powerful toxin causing severe illness and damage to the intestinal lining (CDC, 2011a). The illness is characterized by severe abdominal cramping, watery to bloody diarrhea, dehydration, nausea, and vomiting with or without low-grade fever. **Hemorrhagic colitis** is usually self-limited and lasts for an average of 8 days. Most *E. coli* O157:H7 infections (CDC, 2004) are food-borne and associated with undercooked or raw ground beef, unpasteurized fruit juices and milk, alfalfa sprouts, lettuce, spinach, and fruits. Moreover, outbreaks can be caused by secondary person-to-person contamination in homes, day care centers, nursing homes, and hospitals. Another mode of transmission of *E. coli* O157:H7 is by hand-to-mouth contact with animals or contaminated surfaces at petting zoos and agricultural fairs. Although all people are included in *E. coli* O157:H7 target populations, children and older adults are more susceptible. In cases confirmed in children, infection may develop into **hemolytic uremic syndrome,** leading to permanent loss of kidney function.

Food Safety Practices

The few examples already cited demonstrate how serious food-borne illness can be. Individuals in their own homes can reduce contaminants and keep food safe to eat by following safe food handling practices. Four basic food safety principles work together to reduce the risk of food-borne illness—clean, separate, cook, and chill. These four principles are the cornerstones of Fight BAC!, a national food safety education campaign (http://www.fightbac.org). *Healthy People 2020* included a key food safety objective designed to increase the proportion of consumers following them. As you can see from the following results of the 2006 national Food Safety Survey, there is significant room for improvement (see *Healthy People 2020,* FS-5.1–FS-5.4 for details).

- Clean: Wash hands, utensils, and cutting boards before and after

contact with raw meat, poultry, seafood, and eggs (33% of the surveyed population did not do this) (USDA Center for Nutrition Policy and Promotion 2012).

- Wash all parts of the hands thoroughly with running warm water with soap and friction for approximately 20 to 30 seconds. Teach children to sing the *Happy Birthday* song twice. If no water is available, use alcohol-based (≥60%) hand sanitizers.

- Clean all surfaces with warm, soapy water often (including all appliances, knobs, and handles) and clean up spills immediately. A solution of one tablespoon of unscented, liquid chlorine bleach per gallon of water can be used to sanitize surfaces.

- At least once a week, discard refrigerated foods that should no longer be eaten. Cooked leftovers should be discarded after 4 days; raw poultry and ground meats should be discarded after 1 to 2 days.

- Separate: Do not cross-contaminate. Keep raw meat and poultry separated from foods that will not be cooked while shopping, preparing, or storing foods (11% of the surveyed population did not do this).

- Rinse fresh fruits and vegetables thoroughly with running water before eating, cutting, or cooking them (unless they are prepackaged). Scrub firm surfaces (e.g., cantaloupes and cucumbers) with a

produce brush. Commercial cleaners are unnecessary.

- Cook: Cook food to the proper temperatures and use a food thermometer. The appearance or smell of food does not always indicate its safety.

- Seafood, meat, poultry, and egg dishes should be cooked to the recommended safe minimum internal temperature to destroy harmful microbes. Eggs should be cooked thoroughly, and children should not "lick" the bowls of cake mixes using fresh eggs.

- When food is being cooked in a microwave oven, foods should be stirred, rotated, and/or flipped periodically to help them cook evenly.

- Chill: Refrigerate food promptly within 2 hours, or in 1 hour for environments that are 90°F or hotter. This includes groceries, food being prepared, and leftovers and takeout foods. Keep the refrigerator at 40°F or less and the freezer at 0°F or less and monitor temperatures with a thermometer.

- Keep hot food hot (140°F or higher) and cold foods cold (32–40°F). Between these temperatures is the danger zone in which harmful bacteria can grow rapidly, even exponentially.

- Thaw food properly to avoid any bad bacteria: in the refrigerator; in cold water, such as in a leak-

proof bag, changing the water for cold water every 30 minutes; or in the microwave oven, never on the countertop.

These guidelines also apply to carryout meals, restaurant leftovers, and home-packed meals to go. If in doubt, discard it.

Making a food safe after it has been handled improperly may not always be possible. For example, certain bacteria found in food that has been left at room temperature too long may produce a heat-resistant toxin that cannot be destroyed by cooking. Therefore the principal point is to be careful in preparing food, including cooking foods to the right temperatures, keeping track of the time food is exposed to certain temperatures, and being vigilant when eating out. If there is any doubt about the safety of the food, it is better not to eat it.

Without exception, everyone should exercise their best judgment and care when eating out, when handling their own food, or when handling the food of others. Prevention through education is the key to promoting healthy lives that are unscathed by the potentially severe and life-threatening effects of food-borne illness. On a more positive note, normal healthy adults with healthy immune systems are able to withstand the ill effects of most contaminants from the environment and from food.

Food, Nutrition, and Poverty

As already noted in the discussion of *Healthy People 2020*, a current focus is on attempting to reduce health disparities and health inequities, as well as a focus on future preventive measures. This can be done by healthy food choices being made available wherever people live, work, learn, and play.

Healthy People 2020 goal: Promote health and reduce chronic disease risk through the consumption of healthful diets and achievement and maintenance of healthy body weights.

- Eliminate very low food security among children (from 1.3% of households with children in 2008 to 0.2% in 2020).
- Reduce household food insecurity (from 14.6% in 2008 to 6% in 2020) and in doing so reduce hunger.

Poverty and Income Distribution

For most people in the United States, income has risen over time, providing more options for personal consumption expenditures, including those on food. However, growth in income has not increased equally for all households. Moreover, in recent economic times, people who normally have never needed help have flooded food banks and other federal and community resources (USA Today Supplement, 2010).

According to the US Census Bureau, in 2010 alone, 15.1% of the US population (or 46.2 million people) lived below the poverty level set by the government to determine eligibility for various types of government programs. This was the largest number in 52 years, since the beginning of poverty surveys. Of those people, approximately one-third (35.5%) were children, followed by those with disabilities (28%) and older Americans (25%). Regionally, poverty is concentrated in the South, followed by the West, Midwest, and Northeast. It also appears higher in cities than in rural areas (Nord et al., 2010; US Census Bureau, 2011).

In 2010, the groups with particularly high poverty rates included Hispanics and black Americans, with statistically equivalent poverty rates of 20.6% and 24.3% respectively. Food assistance programs, as discussed next, are one mechanism to provide a limited safety net to keep people from falling further into poverty (Nord et al., 2010).

Food Assistance for Low-Income Individuals

Most Americans are **food secure,** having enough money and resources to obtain adequate food for active, healthy lives. However, for the minority who are living at or below the national poverty line, obtaining a nutritious diet without assistance can be a challenge. Low-income families spend a significantly higher percentage of their annual income on food than other families, often with less access to healthier options such as fresh fruits and vegetables (FRAC, 2016). A variety of federal, state, and local governments and private charitable organizations work to reduce hunger in the United States. The primary responsibility at the federal level falls to the USDA, which administers 15 nutrition assistance programs through the FNS using a combination of federal funding and farm commodities. Programs target the diverse needs of different subgroups of low-income people by providing supplemental assistance through a variety of forms and settings. In 2011, federally funded outlays for nutrition assistance programs resulted in amounts as detailed in the following list (USDA, FNS, 2011a):

- Supplemental Nutrition Assistance Program (SNAP)—formerly known as Food Stamps: $71 billion (Rosenbaum, 2012)
- Child Nutrition Program (includes the National School Breakfast Program [NSBP], the National School Lunch Program [NSLP], the Special Milk Program, the Child and Adult Care Food Program, and the Summer Food Service Program): almost $19.4 billion
- Special Supplemental Nutrition Program for Women, Infants, and Children (WIC): more than $7 billion
- Commodity supplemental food programs (Food Distribution Program on Native American Reservations, Nutrition Services

Incentive Program, the Emergency Food Assistance Program, and farmers' market programs): almost $153 million

One in six people in the United States receive federally funded food assistance at some point every year. The SNAP, NSLP, NSBP, WIC, and Older American Act programs are the main programs that provide food and nutrition assistance. With tightening of federal and state budgets, these programs are continually targeted for significant funding cuts. Table 11-2 provides information on the various programs, along with their website addresses. Income eligibility requirements are based on household income and will change annually. Instructions for applying to the programs may be found directly on the respective websites.

TABLE 11-2

Select Federal Nutrition Assistance Programs

Program	Mission	To Find Out More
Child and Adult Care Food Program (CACFP)	Provide aid to child and adult care institutions and family or group day care homes for the provision of nutritious foods that contribute to the wellness, healthy growth, and development of young children, and to the health and wellness of older adults and chronically impaired disabled individuals	http://www.fns.usda.gov/cacfp/child-and-adult-care-food-program
Child Nutrition Program	Provide healthy food to children from low-income families through a variety of programs, including the National School Lunch Program, the National School Breakfast Program, the Child and Adult Care Food Program, the Summer Food Service Program, the Fresh Fruit and Vegetable Program, and the Special Milk Program	http://www.fns.usda.gov/school-meals/child-nutrition-programs
Supplemental Nutrition Assistance Program (SNAP)	Offer nutrition assistance to low-income individuals and families and provide economic benefits to communities	http://www.fns.usda.gov/snap/supplemental-nutrition-assistance-program-snap
Special Supplemental Nutrition Program for Women, Infants, and Children	Provide federal grants to states for supplemental foods, health care referrals, and nutrition education for low-income pregnant, breastfeeding, and nonbreastfeeding postpartum women, and to infants and children up to age 5 years who are found to be at nutritional risk	http://www.fns.usda.gov/wic/women-infants-and-children-wic

(WIC)		
Food distribution programs	To strengthen the nation's nutrition safety net by providing food and nutrition assistance to schoolchildren and families; and support American agriculture by distributing high-quality, 100% American-grown USDA foods. The programs include the following: the Commodity Supplemental Food Program, the Food Distribution Program on Indian Reservations, The Emergency Food Assistance Program, the Nutrition Services Incentive Program, the DoD Fresh Fruit & Vegetable Program, and the Child Nutrition USDA Foods Program	http://www.fns.usda.gov/fdd/food-distribution-programs

DoD, Department of Defense; *USDA,* US Department of Agriculture.

Modified from US Department of Agriculture, Food and Nutrition Service. (2016). *Programs and services.* Washington, DC. http://www.fns.usda.gov/programs-and-services.

Supplemental Nutrition Assistance Program

SNAP supplements the food-buying power of eligible low-income households and is the foundation of the nations' nutrition safety net. Benefits are provided through an electronic benefit transfer (EBT) card that participants use to purchase food at authorized stores. It is designed to help low-income families and individuals purchase nutritionally adequate foods. Households can use their EBT card to purchase any food or food product for home consumption, as well as seeds and plants for use in home gardens. Restaurants can be authorized to accept EBT cards from qualified homeless, older, or disabled people in exchange for low-cost meals. Items that recipients cannot buy with EBT cards include alcoholic beverages, tobacco, hot ready-to-eat foods, lunch-counter items, and foods to be eaten in the store, vitamins, medicines, and pet foods.

Although there is no requirement that the EBT card be used to purchase nutrient-dense food, the goal of the SNAP nutrition education program is to increase the likelihood that recipients will make healthy food choices within their limited food budget. SNAP uses multiple strategies to facilitate healthy food choices and active lifestyles. These include providing nutrition education programs;

encouraging more farmers' markets, small urban markets, and bodegas to participate in the program; and offering a demonstration project to examine the impact of incentives on participant purchases of fruits and vegetables.

The program is administered nationally by the FNS and locally by state and welfare agencies in all 50 states, the District of Columbia, Guam, and the US Virgin Islands. Eligibility is based on financial factors such as income and expenses available to the household, as well as 5 years of legal immigrant status, if applicable. SNAP requires most able-bodied adults aged between 16 and 60 years (with few exceptions) to register for work, to take part in employment/training programs referred by the SNAP office, and to accept or continue in suitable employment. Households may own certain limited resources. In addition to income, the EBT allotment is also based on family size. In contrast to public perception, less than 10% of households received cash welfare in 2009, and the latest statistics from 2010 showed 40% of households had at least one wage earner. In addition, according to FNS data, most households advance from SNAP in less than 1 year (Rosenbaum, 2012). In 2011, 92% of SNAP funding went directly to 40.3 million people: 48% children, 44% adults, and 8% adult aged 60 years or older. The average monthly benefit per person was approximately $134 and almost $290 per household (USDA, FNS, 2011b).

With passage of the 2012 Farm Bill, approximately $4.5 billion will be cut from SNAP, with an estimated loss of 500,000 possible recipients and almost $90 less in benefits per household.

Child Nutrition Program

Collectively called the “Child Nutrition Program,” these programs provide cash reimbursement and commodity support for meals served to children in schools, child care facilities, and summer settings. They include the NSLP, the NSBP, the Child and Adult Care Food Program, the Summer Food Service Program, and the Special Milk Program. The general purpose of these programs is to help ensure the health and well-being of all the nation's children. The two

biggest and most well-known programs are described next.

National school lunch program.

The federally funded NSLP is administered by the FNS. On the state level, the NSLP is usually administered by the US Department of Education, which contracts with local public, nonprofit private, and residential child care centers and schools to provide balanced, low-cost or free lunches. The NSLP reaches approximately 31.6 million children each school day (FRAC, 2016), including the following:

- Children from families with incomes at or below 130% of the federal poverty level guidelines are eligible for free school meals.
- Children from families with incomes above 130% to 185% of the poverty level are eligible for reduced-price school meals.
- Children from families with incomes more than 185% of the poverty level are eligible for full-price school meals.

Schools that choose to take part in the lunch program must implement wellness policies that promote healthy eating, address obesity, and encourage physical activity. Schools are provided with cash subsidies and approved agricultural commodities from the USDA as a supplement. Up to January 2012, free, reduced-price, or full-price lunches had to meet the following federal minimum pattern requirements:

- Must provide one-third of the recommended nutrient intake of 1989 RDAs
- To the extent possible, be consistent with the *Dietary Guidelines for Americans* recommendations for reducing sugar, salt, and fat intake

Under the Healthy Hunger-Free Kids Act of 2010, the USDA gained authority to set policy and nutrition criteria for all child nutrition standards, including the NSLP. New meal standards were published in 2012 based on the 2009 IOM recommendations to move subsidized meals into line with the *Dietary Guidelines for Americans* and the DRIs (Stallings et al., 2010; USDA, FNS, 2011b). The new rules stipulate a doubling of previous amounts of fruits and vegetables served in schools, set limits on the levels of **trans fats** and salt, increase the

amount of whole grains served, make 1% and fat-free milk the norm, and establish suitable ranges for daily calorie intake. They also require free drinkable water in food service areas and increase subsidies to schools following the new guidelines. Even with changes, the NSLP budget projections are less than the current budget by eliminating the meat/meat substitute requirement at breakfast, allowing a phase-in period for fruits and vegetables, honoring requests to take smaller portions, and discontinuing price supports for meals, including separately priced items.

National school breakfast program.

The NSBP was designed to make it possible for all schoolchildren to receive a nutritious breakfast every day. Skipping breakfast can adversely affect children's performance potential. The NSBP provides assistance to states to initiate, maintain, or expand nonprofit breakfast programs in eligible schools and residential child care institutions. Any child attending a participating school may receive a free, reduced-price, or full-price breakfast based on the same income criteria used by the NSLP. In the 2010 to 2011 school year, 11.7 million children in almost 88,000 schools were fed every day (FRAC, 2016).

Special Supplemental Nutrition Program for Women, Infants, and Children

WIC supplies free nutritious supplemental food, nutrition counseling, breastfeeding support, and health and social service referrals to eligible low-income pregnant or postpartum women and to children younger than 5 years old who are at nutritional risk. Congress funds WIC every year for a specific amount as a federal grant program to be administered by FNS and 90 “state” agencies (including 50 states, 34 tribes, the District of Columbia, and 5 US territories). Services are offered in a wide variety of settings: county health departments, hospitals, mobile clinics, community centers, schools, public housing sites, Indian reservations, migrant health centers and camps, and Indian Health Service facilities.

Eligibility is based on the following factors. Income must be 185% or less of the US poverty income guidelines (approximately $41,000 for a family of four in 2009), and participants must meet one of two major types of nutritional risk:

- Medically based risks, such as anemia, **underweight,** maternal age, history of pregnancy complications, or poor pregnancy outcome
- Diet-based risks, such as inadequate dietary pattern as determined by 24-hour recall, food frequency questionnaire, or diet history

Those who qualify usually receive monthly checks or vouchers to buy foods designed to augment their diet with specific nutrients. In addition, a growing number of state agencies issue an electronic benefit card (like a debit card), and some distribute WIC foods through warehouses or deliver WIC foods to recipients' homes. The foods differ depending on an individual's specific food package designation but can include iron-fortified infant cereal, iron-fortified adult cereal, fruit or vegetable juice rich in vitamin C, eggs, milk, cheese, and peanut butter or dried beans. WIC recognizes and promotes breastfeeding as the optimal source of nutrition for infants. For women who do not breastfeed, WIC provides iron-fortified infant formula. Special infant formulas and medical foods may be provided when prescribed by a physician for a specified medical condition. In 2009 new foods were added and specific food packages were reformulated to improve variety, to increase flexibility for diverse cultures, and for alignment with the *Dietary Guidelines for Americans* and American Academy of Pediatrics infant feeding practice guidelines. These foods include soy-based beverages, tofu, fruits and vegetables, baby foods, whole-wheat bread, and other whole-grain options.

Each WIC participant receives vouchers with maximum monthly allowable amounts of particular components specially designed for the following categories: fully breastfeeding mother; pregnant or partially breastfeeding mother; postpartum, fully formula feeding mother; fully breastfed baby; partially breastfed baby; fully formula-fed baby; and children 1 to 5 years old (California WIC Association, 2009).

Of the 9.17 million people who received WIC benefits each month in 2011, approximately 4.86 million were children, 2.17 million were infants, and 2.14 million were women (USDA, FNS, 2011a). Financial constraints preclude WIC from serving all eligible people; therefore a system of priorities has been established for filling program openings. After a local WIC agency has reached its maximum caseload, vacancies are filled in the order of the following priority levels:

- Pregnant women, breastfeeding women, and infants determined to be at nutritional risk of serious medical problems
- Infants up to 6 months of age whose mothers participate in WIC or are eligible to participate and have serious medical problems
- Children up to age 5 years at nutritional risk of serious medical problems
- Pregnant or breastfeeding women and infants who are at nutritional risk of dietary problems
- Children up to age 5 years at nutritional risk of dietary problems
- Nonbreastfeeding postpartum women with any nutritional risk
- Individuals at nutritional risk only because they are homeless or migrants and current participants who would likely continue to have medical or dietary problems without WIC assistance

WIC funding may be inadequate in the future to fund the increased numbers of expected participants (National WIC Association, 2014). For state agencies that apply for a grant, the WIC Farmers' Market Nutrition Program (or WIC FMNP) gives additional coupons to people to use to purchase fresh fruits and vegetables at participating farmers' markets. The WIC FMNP has two goals: to provide fresh, nutritious, unprepared, locally grown fruits and vegetables from farmers' markets to WIC participants, and to expand consumers' awareness and use of farmers' markets.

The overall statistics on WIC demonstrate it is effective in improving the health of its participants. Medicaid costs for women who participate in the program during pregnancy and their infants are lower than those for women who do not participate. WIC participation is also linked to longer gestation periods, higher birth

weights, and lower infant mortality rates (USDA, FNS, Office of Research and Analysis, 2012).

Food and Nutrition Programs for Older Adults

At the other end of the life cycle, a significant number of older people face special obstacles to obtaining an optimal diet. Of particular concern are adults older than 75 years who are frail, alone, or restricted to a limited budget. Life changes such as the loss of a spouse/significant other; sensory changes in taste or smell; physical inability to obtain food; and decreasing calorie needs can make acquisition of an adequate diet challenging.

A variety of nutrition assistance programs are available to this population. They include SNAP, the Senior Farmer's Market Nutrition Program, the Child and Adult Care Food Program, The Emergency Food Assistance Program, and the Commodity Supplemental Food Program. However, the programs that most people may be familiar with are some of those provided under the Older Americans Act, collectively called the Elderly Nutrition Services Program, which are managed by the Administration on Aging (AoA) through the USDHHS. They are designed to help older adults access nutritionally sound meals, obtain nutritional services and other health-promotion services (including nutrition screening and counseling), and reduce the social isolation that may occur in old age. Priority is given to older people with the greatest social and economic need: low income, minorities, those with limited English proficiency, rural location, and frail seniors at risk of institutionalization (USDHHS, AoA, 2009).

The older adults nutrition services program.

This program includes the Congregate Nutrition Services Program (CNSP), the Home-Delivered Nutrition Services Program (i.e., "Meals on Wheels"); and the Nutrition Services Incentive Program (NSIP), which gives states, territories, and Indian tribal organizations (ITOs) the ability to purchase food or to cover the cost of commodities from the USDA for the CNSP and the Home-Delivered Nutrition Services Program. The AoA provides funds to states, territories, and ITOs, and

it awards money to Area Agencies on Aging for coordination with area food sites such as senior centers, faith-based sites, community centers, adult day care centers, and schools. For NSIP, the share of the population who received meals under CNSP or Meals on Wheels in the preceding year determines money or commodity allocation.

By law, age is the only factor used in determining eligibility. People aged 60 years or older and their spouse or caretaker, regardless of age, are eligible for benefits. ITOs may select an age younger than 60 years for the definition of an older person for their tribes because of a shorter life expectancy and higher incidence of chronic illnesses. Additionally, disabled people who live in elder care housing facilities, people who accompany older participants to congregate feeding sites, and volunteers who assist in the meal service may also receive meals. For those in the Home-Delivered Nutrition Services Program, spouses of any age and disabled persons may also participate as long as they live with the homebound elder.

Additionally, by law, there is no income requirement for meals. Each recipient may contribute as much as desired toward the cost of the meal, but meals are free to people who cannot make any contribution. As of 2011, federal money contributed only approximately 42% of the money for these programs; 15% came from state funding, with the balance coming from local, private, or participant contribution (Johnson, 2011). In recent years, many states have shifted allowable money from congregate feeding sites into Meals on Wheels or other nutrition/health-promotion programs to help keep older adults in their communities. Even so, long waiting lists for Meals on Wheels are not uncommon and volunteers to help deliver meals to stretch limited dollars are always needed. This situation is not likely to improve with continuing federal and state budget constraints.

In 2010, 92.5 million meals, or approximately 40% of total meals, were served in congregate settings to just less than 1.69 million meal participants. A 2009 report by the AoA showed 57% of those people were aged 75 years or older, 48% lived alone, 13% had annual incomes of $10,000 or less, and 57% stated the meal provided half or more of

their daily food intake. Participants also said they saw friends more often because of meals (87%). For every 10 meals, 6 were delivered to homebound elderly people, for a total of 149.2 million home-delivered meals to approximately 880,000 meal participants. Of those older people, 70% were aged 75 years or older, 56% lived alone, 25% had an annual income of $10,000 or less, and 59% said the meals provided half or more of their daily food intake. Four in 10 people needed help with at least one activity of daily living, and 85% needed help with shopping, housework, and ambulating.

Nutrition Screening

Nutrition screening is the process of discovering characteristics or risk factors that are known to be associated with dietary or nutrition problems. Its primary purpose is to identify individuals (such as older adults and the poor) who are potentially at high risk of complex and involved problems that relate to nutrition. To serve this purpose, screening criteria must be simple, relatively straightforward, and easy to administer. Screening is also helpful in establishing priorities for the most efficient use of valuable time and money.

The single largest demographic group at disproportionate risk of malnutrition is older Americans. Nutrition screening holds a tremendous preventive health potential for older adults. The nurse should assess the need for nutrition counseling or a referral to a registered dietitian for an older person who has food-related problems that are impacting eating pleasure and quality of life (American Dietetic Association, 2010a). The pendulum has shifted to reduce unnecessary therapeutic diets for those at risk of unintentional weight loss and undernutrition. There is also controversy about the benefit of weight loss for obese older Americans except if their laboratory test results indicate risk of metabolic syndrome. A dietitian or community nutrition program might be appropriate if any of the following are identified in the individual:

- Inappropriate or inadequate food intake
- Desire by obese elderly person to lose weight—tailoring to provide adequate calories, protein, and physical activity to preserve lean body mass
- Need for nutrient/disease-specific counseling with specific food preferences, cultural taboos, or environmental constraints
- Serum cholesterol levels of more than 240 mg/dL with desire to change eating pattern
- Inability to self-feed or to prepare and purchase food, or inability to carry out food-related activities of daily living

The health care professional should refer the individual to a physician when there has been an involuntary decrease in weight of more than 10 pounds during the previous 6 months. Additional anthropometric measurements suggesting malnutrition include the following:

- Triceps skin-fold thickness less than the 10th percentile
- Mid-arm muscle circumference less than the 10th percentile
- Serum albumin level less than 3.5 g/dL
- Evidence of osteoporosis or mineral deficiency (indicated by a history of bone pain or fractures, particularly in housebound older women)
- Evidence of vitamin deficiency (indicated by long-term inadequate fruit and vegetable intake; angular stomatitis, glossitis, or bleeding gums; or pressure sores in bedridden individuals)

Nutrition Risk Factors

This section examines the role of nutrition in the cause and prevention of the leading nutrition-related chronic diseases—**heart disease,** stroke, some forms of cancer, osteoporosis, obesity, and **type 2 diabetes**—and in the early treatment of people in whom **human immunodeficiency virus** (HIV) infection was recently diagnosed.

Cardiovascular Diseases

Cardiovascular diseases (CVDs), principally CHD and stroke, are among the leading killers of both men and women among all racial and ethnic groups in the United States. Approximately one-fourth of the US population has some form of CVD, including hypertension, CHD, and stroke.

CVD prevention is so important that *Healthy People 2020* has specific objectives to improve cardiovascular health and quality of life through prevention, detection, and treatment of risk factors for heart attack and stroke. Specific objectives are listed in Box 11-2: *Healthy People 2020*.

Heart Disease

Diet Intervention

In an attempt to reduce the incidence of CVD, the American Heart Association (AHA) recommends that people older than 2 years adopt a well-balanced diet (Box 11-6: Research for Evidence-Based Practice), achieve and maintain a healthy body weight, and reach optimal levels for total cholesterol, **high-density lipoprotein** (HDL) **cholesterol, low-density lipoprotein** (LDL) **cholesterol**, blood pressure, and blood glucose (Lichtenstein et al., 2006). (The AHA did not set guidelines for children younger than 2 years.)

Box 11-6

Research for Evidence-Based Practice

Dietary Risk Factors and Heart Disease[a]

Developing guidelines and recommendations for preventing heart disease is a topic that is routinely reassessed. You may ask, "Why do the recommendations change over time?" As with all things scientific, technology is ever-growing and advancing. Such scientific progress brings new findings, for which guidelines are amended. The gold standard in medicine is to base all medical intervention protocols on evidence-based practice. Evidence-based practice is the use of current evidence from available research coupled with clinical expertise to establish high-quality patient care.

CVD is the leading cause of death in the United States, and suboptimal diet quality is the single largest risk factor contributing to death and disability. The American Heart Association notes that the primary contributors to poor dietary habits are insufficient consumption of fruits, vegetables, nuts/seeds, whole grains, and seafood and an excessively high intake of sodium (Mozaffarian et al., 2016). The American Heart Association's evidence-based practice guidelines to prevent CVD encourage American's to achieve at least four of the five following key components of a healthy diet:

- Fruits and vegetables: consume more than 4.5 cups per day
- Fish: consume more than two 3.5-oz servings per week (preferably oily fish)
- Fiber-rich whole grains (>1.1 g of fiber per 10 g of carbohydrates): consume three 1-oz-equivalent servings per day
- Sodium: limit to less than 1500 mg per day
- Sugar-sweetened beverages: limit to less than 450 kcal (36 oz) total per week

Considering that only 1.5% of adults and less than 1% of children in the United States currently meet these healthy diet criteria, there is a lot of room for improvement.

[a]With contribution from Staci Nix.

From Mozaffarian, D, Benjamin, E. J., Go, A. S., Arnett, D. K., Blaha, M. J., Cushman, M., et al. (2016). Heart disease and stroke statistics—2016 update: A report from the American Heart Association. *Circulation*, *133*, e38–e360.

However, eating two or more servings of fish (approximately 8 ounces) every week, preferably oily varieties rich in eicosapentaenoic acid or docosahexaenoic acid, omega-3 fatty acids, such as canned light tuna, salmon, pollock, and catfish seems safe.

Smaller fish may have less mercury contaminants than larger ones.

- Limit intake of saturated fat to 10% of energy by choosing lean meats and vegetable alternatives, and fat-free (skim) or low-fat (1% fat) dairy products.
- When eating food prepared outside of the home, follow these diet and lifestyle recommendations:
- Reduce salt intake by comparing the sodium content of similar products (e.g., different brands of tomato sauce) and choosing products with less salt or sodium; choosing versions of processed foods, including cereals and baked goods, that are reduced in salt or sodium; and limiting consumption of condiments (e.g., soy sauce, ketchup).
- Neither antioxidant vitamin supplements nor other supplements such as selenium are recommended.

Many children, adolescents, and adults who already have unhealthy levels of lipids in their blood should receive nutrition counseling (Grundy et al., 2004). In children aged 2 to 20 years, an acceptable level of total cholesterol is less than 170 mg/dL.

Individuals with LDL cholesterol levels that are higher than 100 mg/dL should be advised to reduce their dietary intake of saturated

fat and cholesterol to levels below those recommended for the general population (Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults, 2001). The upper limit for these individuals is less than 7% of the total energy for saturated fat and less than 200 mg of cholesterol per day. The *Dietary Guidelines for Americans 2015–2020* does not set specific quantitative limits for dietary cholesterol consumption per day. However, the healthy eating patterns that are recommended are naturally low in cholesterol, with approximately 100 to 300 mg of dietary cholesterol per day. Individuals at risk of heart disease may be advised to further limit their cholesterol intake, particularly if their LDL cholesterol levels are high. After the dietary intervention has been outlined to the individual, follow-up sessions are scheduled to monitor lipid levels and dietary adherence.

The National Cholesterol Education Program (NCEP) develops new guidelines periodically, as warranted by research advances. The most recent set of guidelines, the *Third Report of the NCEP Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults,* also known as the Adult Treatment Panel III (ATP III) (Table 11-3), was updated in 2004. The changes in options for more intensive cholesterol level reduction treatment for high-risk and moderate-risk individuals were based on the review of five clinical trials of cholesterol-lowering statin treatment. The update did not change the ATP III recommendations for people at moderate or lower risk. The ATP guidelines recommend that healthy adults have a lipoprotein analysis once every 5 years. A lipoprotein profile measures levels of LDL cholesterol, total cholesterol, HDL cholesterol, and triglycerides (fat in the blood). The level at which HDL becomes a major risk factor for heart disease is less than 40 mg/dL for men and less than 50 mg/dL for women.

TABLE 11-3

Cholesterol and Lipoprotein Profile Classification

Cholesterol Reading Classification
Total Cholesterol (mg/dL)

<180	Optimal
<200	Near optimal
200–239	Borderline high
≥240	High
Low-Density Lipoprotein Cholesterol (mg/dL)	
<100	Optimal
100–129	Near optimal
130–159	Borderline high
160–189	High
≥190	Very high
High-Density Lipoprotein Cholesterol (mg/dL)	
≥60	Optimal
40–59	Borderline/normal
<40	A major risk factor for heart disease
Triglycerides (mg/dL)	
<150	Optimal
150–199	Borderline high
200–499	High
≥500	Very high

Modified from Nix, S. (2017). *Williams' basic nutrition and diet therapy* (15th ed.). St. Louis: Elsevier.

In addition to a low HDL level, there are other major risk factors for CHD:

- Clinical forms of atherosclerotic disease (peripheral arterial disease, abdominal aortic aneurysm, and symptomatic carotid artery disease)
- Age (≥45 years for men and ≥55 years for women)
- Cigarette smoking
- Hypertension (blood pressure ≥140/90 mmHg or taking antihypertensive medication)
- Family history of premature heart disease (heart disease in a first-degree relative at age less than 55 years for men or at age less than 65 years for women)
- Type 1 diabetes
- Obesity
- Metabolic syndrome

HDL cholesterol level greater than 60 mg/dL is considered a negative risk factor.

Therapeutic Lifestyle Changes Treatment Plan

The therapeutic lifestyle changes (TLC) treatment plan of nutrition, physical activity, and weight control is recommended for treatment of people who present with type 2 diabetes, elevated levels of LDL, or **metabolic syndrome.**

Metabolic syndrome describes the presence of a cluster of risk factors that often occur together, which dramatically increases the risk of coronary events. The syndrome is diagnosed when an individual has three or more of the following factors:

- Excessive abdominal fat, as indicated by too large a waist measurement (>35 inches or 88 cm in women and >40 inches or 102 cm in men)
- Elevated blood pressure (higher than 130 mmHg systolic or 85 mmHg diastolic)
- Low HDL level (<40 mg/dL)
- Elevated **triglyceride** level (>150 mg/dL), which is significantly linked to the degree of heart disease risk. (The guidelines recommend even borderline high triglyceride levels be treated with therapy that includes weight control and physical activity.)

The dietary component of the TLC treatment plan includes the following daily intake:

- Less than 7% of calories from saturated fat
- Less than 200 mg of dietary cholesterol
- Up to 35% of calories from total fat, provided most of the fat is unsaturated fat, which does not raise cholesterol levels. (A higher fat intake may be needed by some individuals with high triglyceride levels or a low HDL level, or both, to prevent their triglyceride levels or HDL status from increasing.)
- Intake of certain foods to boost the diet's LDL-lowering power: 2 g/day of plant stanols and sterols found in cholesterol-lowering margarines and salad dressings, and 10 to 25 g/day of foods high in soluble fiber, such as cereal grains, beans, peas, legumes, and many fruits and vegetables

A primary treatment goal of the TLC treatment plan is reduction of

an elevated LDL level to:

- Less than 100 mg/dL with a therapeutic option of less than 70 mg/dL in the presence of CHD or other forms of atherosclerotic disease
- Less than 130 mg/dL with a therapeutic option of less than 100 mg/dL in the presence of two or more risk factors for CHD
- Less than 160 mg/dL in the presence of fewer than two risk factors for CHD

The final goal of the TLC treatment plan includes weight control (to enhance LDL level lowering and raise HDL level) and physical activity that lasts at least 30 minutes, expending at least 200 calories per day on most days (to decrease HDL and, for some, LDL levels).

Removing Barriers to Treatment Goals

To improve an individual's adherence to ATP III goals, treatment barriers can be eliminated by the development of protocols to encourage long-term individual adherence and follow-up, such as establishing clinic policy and developing computerized databases for those seeking care, establishing management algorithms, reinforcing and rewarding adherence, and enhancing third-party reimbursement. The nurse uses behavioral theories to identify a person's level of readiness to change and focus on counseling strategies to match that level of readiness (Snetselaar, 2004).

Hypertension

Blood pressure, the force of blood against the walls of arteries, is recorded as the systolic pressure (as the heart beats) over the diastolic pressure (as the heart relaxes between beats). The measurement is written with one number above (or before) the other, with the systolic blood pressure (SBP) listed first and the diastolic blood pressure (DBP) listed second. For example, a blood pressure measurement of 120/80 mmHg is expressed verbally as “120 over 80.” Normal blood pressure is less than 120 mmHg systolic and less than 80 mmHg diastolic. *The Seventh Report of the Joint National Committee on*

Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (National High Blood Pressure Education Program, 2003) added a **pre-hypertension** classification defined as an SBP range of 120 to 139 mmHg or a DBP range of 80 to 89 mmHg to highlight increased risk of progression to frank hypertension and CVD (National High Blood Pressure Education Program, 2003). A more recent review by the panel members appointed to the Eighth Joint National Committee (JNC 8) did not readdress the definitions of hypertension and pre-hypertension, but reexamined and redefined thresholds for drug treatment (James et al., 2014). JNC 8 also found strong evidence to address treating hypertensive 60-year-old or older individuals to a goal blood pressure of 150/90 mmHg and younger hypertensive individuals aged 30 to 59 years to a DBP of less than 90 mmHg (James et al., 2014). On the basis of this evidence, *Healthy People 2020* contains objectives related to pre-hypertension (see Box 11-2: *Healthy People 2020*).

Epidemiology

In 2008 **hypertension** contributed to the deaths of approximately 348,000 Americans out of 2.4 million people. Approximately 44% were men and 56% were women (Roger et al., 2012). If a definition of hypertension as blood pressure higher than 140/90 mmHg is used, as many as 76.5 million adult Americans, or nearly one-third of all adults in the United States, have high blood pressure. NHANES data from 2005 to 2008 show that one in three people with hypertension are unaware of their condition, and over 50% of those surveyed do not have controlled high blood pressure (Egan et al., 2011). Untreated hypertension can damage arteries and increase the risk of stroke and congestive heart failure. High blood pressure is also responsible for many cases of kidney failure requiring dialysis and increases the risk of kidney failure in people with diabetes.

Non-Hispanic black and non-Hispanic white Americans are more likely to have high blood pressure than are Hispanic Americans although the rates for all ethnicities are significant. More women than men (3 in 4) have high blood pressure at age 75 years or older. It

appears to affect more people with lower educational and income levels, although this may be related to other factors.

Diet Intervention

The modifiable nutrition-related risk factors for stroke include high blood pressure, obesity, habitual high alcohol intake, and high intake of sodium (Appel et al., 2006; CDC, 2011c; Lloyd-Jones et al., 2010). However there appears to be no need to restrict salt intake to less than the suggested 2000 mg currently in the guidelines for everyone with mild hypertension. There appears to be a class of hypertensive individuals who are salt sensitive who benefit from sodium restriction (Sanada et al., 2011). No certain method exists for identifying susceptible people or ascertaining how many of them become hypertensive as a result of excessive salt intake; therefore the conservative preventive health approach recommends a daily salt intake limited to 6 g or less for adults. Sodium chloride is approximately 40% sodium by weight; therefore a diet with 6 g of salt contains approximately 2300 mg of sodium. This amount is regarded as mild sodium restriction. Ideally, the recommendations are to reduce sodium intake to approximately 1500 mg, but this is very difficult with the current prevalence of sodium in packaged and restaurant foods. More than 45 national health organizations and 20 restaurant and food packaging companies have so far joined in the National Salt Reduction Initiative, started by New York City mayor Michael Bloomberg in 2008; the initiative aims to reduce the sodium level in food by 25% over 5 years. The following are the three major sources of sodium in the US diet, in order of predominance:

- Salt added by food processing companies as an ingredient in almost all processed foods (including many foods that do not taste salty, such as baked goods); most processed foods have a high sodium content (80%)
- Salt added by consumers to food during cooking or at the table (5–6% each)
- Salt from all animal products, which are a natural source of sodium

The following recommended food tips are designed to reduce salt and sodium intake:

- Sodium occurs naturally in many foods and is also added to most processed foods; therefore add salt only sparingly in home cooking and at the table.
- Consume fewer foods that have high sodium levels, such as many cheeses; processed meats; most frozen dinners and entrees; packaged mixes; most canned soups and vegetables; salad dressings; and condiments such as soy sauce, pickles, olives, catsup, and mustard.
- Rinse canned vegetables before warming them.
- Eat salty, highly processed salty, salt-preserved, and salt-pickled foods infrequently.
- Check labels for the amount of sodium in foods and choose products lower in sodium (free, <5 mg per serving; low, <140 mg per serving; reduced or less, 25% less than standard-reference food; healthy, <480 mg per serving).

Dietary Approaches to Stop Hypertension Eating Plan

Clinical studies show that following the DASH eating plan helps to lower blood pressure. The National Heart, Lung, and Blood Institute, with additional support by the NIH, funded the DASH research, with the final results appearing in 1997. The DASH eating plan makes consuming less salt and sodium easier because the plan includes abundant fruits and vegetables, which are lower in sodium but higher in potassium than other foods. Potassium and sodium play important roles as electrolytes in intracellular and extracellular fluid balance. People at high risk of hypertension may have a high sodium intake that may upset the sodium-to-potassium ratio, and eating more vegetables and fruits may account for the success of the DASH diet. The plan also includes more fat-free or low-fat milk and milk products, whole grains, fish, poultry, beans, seeds, and nuts, but contains less sweets, added sugars and sugar-containing beverages,

fats, and red meats than the average typical American diet.

The plan is rich in magnesium, potassium, calcium, protein, and fiber. At approximately 2100 calories a day, the nutrients include 4700 mg of potassium, 500 mg of magnesium, and 1250 mg of calcium. These totals are approximately two to three times the amounts most Americans receive.

On the basis of the findings of DASH clinical studies, a combination of the eating plan and reduced sodium intake can reduce elevated blood pressure or prevent it when blood pressure is normal. The plan may even eliminate the need for medication or, in the case of severe high blood pressure, allow a reduction in medication. Other steps to control or prevent hypertension should continue to be encouraged, including exercise weight loss when necessary, not smoking, and limiting alcohol consumption. DASH may also improve health in other ways. The potassium in fruits and vegetables helps reduce hypertension (AHA, 2016) and may reduce the risk of some cancers; the calcium in dairy products may reduce fat mass and thus hypertension (Zemel, 2001). The diet may help lower the risk of osteoporosis, and a diet low in saturated fat and cholesterol can reduce CVD risk. The complete DASH eating plan entitled *Your Guide to Lowering Your Blood Pressure With DASH* (USDHHS, NIH, National Heart, Lung, and Blood Institute, 2006) can be obtained from http://www.nhlbi.nih.gov/health/resources/heart/hbp-dash-index.

Cancer

Epidemiology

The National Cancer Institute estimates that almost one in two (41%) women and men will receive a diagnosis of some type of cancer in their lifetime. Cancer remains the second leading cause of death in the United States (American Cancer Society, 2017; Miniño, 2011).

The most common cancers in in men and women are lung, colorectal, prostate and breast; these cancers apprise approximately 46% of cancer deaths. Over 25% of cancer deaths are due to lung cancer. For men in 2017, 42% of new cases will occur at prostate, lung,

and colorectal sites; in women the most common sites are breast, lung, and colorectal. Breast cancer alone accounts for 30% of newly diagnosed cases (American Cancer Society, 2017).

Approximately one-third of cancer deaths among men and women are related to diet and sedentary lifestyle factors. The introduction of a healthy diet (Figure 11-4) and exercise practices at any time from childhood to old age can promote health and likely reduce cancer risk.

FIGURE 11-4 Teenagers who help to prepare safe, nutritious meals become engaged in the healthy eating process (From Mahan, L. K., & Raymond, J. L. [2017]. *Krause's food & the nutrition care process* [14th ed.]. St Louis: Elsevier.)

Diet Intervention for Risk Reduction

Many dietary factors can affect cancer risk: types of foods, food preparation methods, portion sizes, food variety, and overall calorie balance. An overall dietary pattern that balances calorie intake and physical activity for weight management along with inclusion of a high proportion of plant foods (fruits, vegetables, whole grains, and beans) and limited amounts of processed or red meats and whole-fat dairy products may reduce the risk of cancer. The phytochemicals in

fruits and vegetables, in particular, appear to have a protective effect by themselves, but dietary supplements, in particular supplements that exceed DRIs, do not provide the same benefits.

Based on its review of the scientific evidence, the American Cancer Society (ACS) updated its nutrition and physical activity guidelines in 2011 (Kushi et al., 2012). The ACS recommendations are very consistent with the messages of the *Dietary Guidelines for Americans 2015–2020,* the MyPlate guidelines, and the dietary recommendations of other national agencies for general health promotion and prevention of other diet-related chronic conditions. Although no diet can guarantee full protection against any disease, the ACS believes that the following recommendations offer the best nutrition information currently available to help Americans:

- For national, state, and local community action:

- Apply policy and environmental changes that increase access to affordable, healthy foods in all places where adults and children live, work, go to school, or play and decrease access and marketing of foods and drinks of low nutritional value, particularly to youth.

- For individuals:

- Choose most of the foods you eat from plant sources. Choose fewer and smaller portions of high-fat or calorie-dense foods and beverages. Eat at least 2.5 cups of a variety of fruits and vegetables every day. Choose whole-grain breads, cereals, pastas, brown rice, and beans. Limit consumption of processed meat (bacon, sausage, luncheon meats)

and red meats such as beef, pork, or lamb. For those who do eat meat, choose leaner cuts and small portions, not more than one-quarter of the plate (similar to the MyPlate recommendation). Many scientific studies show that eating fruits and vegetables (especially green and dark yellow or orange vegetables, foods in the cabbage family, soy products, and legumes) may protect against cancers at many sites, particularly for cancers of the gastrointestinal and respiratory tracts. Consumption of at least five servings of fruits and vegetables among both smokers and nonsmokers seems to reduce the risk of lung cancer. Grains as well as fruits, vegetables, and dairy products are also an important source of many vitamins and minerals, such as folate, calcium, and selenium, which have been associated with a lower risk of colon cancer in some studies. Beans (legumes) are especially rich in nutrients that may protect against cancer. Consumption of meat, particularly red and processed meats, has been associated with an increased risk of cancer at several sites, most notably the colon, stomach, and prostate.

- Since 1991 the 5 A Day for Better Health Program (now Fruits and Veggies—More Matters) has raised public awareness about the importance of fruits

and vegetables in disease prevention. The program is jointly sponsored by the CDC and the Produce for Better Health Foundation (a nonprofit consumer education foundation representing the fruit and vegetable industry). Through its unique national public-private partnership, Fruits and Veggies—More Matters seeks to increase consumption of fruits and vegetables to five or more servings each day. The program focuses on mothers as the gatekeepers for families for the most part and provides information, recipes, and materials for both consumers and partner organizations. It gives Americans a simple, positive message: eat more fruits and vegetables, start small, and aim for variety.

- Be physically active: achieve and maintain a healthy weight. Being overweight or obese, by itself or in combination with excess belly fat, increases the risk of cancers at several sites, such as the colon and rectum, prostate, endometrium, breast (among postmenopausal women), and kidney. Both increasing physical activity and balancing food intake to maximize nutrient density within calorie needs are essential. Keeping a healthy BMI without being underweight is ideal. If overweight, avoidance of more weight gain or even losing as

little as 5% to 10% of weight can be beneficial.

- For those who drink alcohol, limit consumption. No more than one drink per day for women or two drinks per day for men should be the limit. Alcoholic beverages, along with cigarette smoking and the use of tobacco products, contribute to cancers of the oral cavity, esophagus, and larynx. Studies have also shown an association between alcohol consumption and an increased risk of breast cancer (American Cancer Society, 2009). The mechanism of this effect is not known, but the association may be related to the carcinogenic effects of alcohol or its metabolites, to changes in levels of hormones such as estrogens, or other processes. Regardless of the mechanism, studies show that the risk of breast cancer increases with an intake beginning at only a few drinks per week. Reducing alcohol consumption is a good way for women who drink regularly to reduce their risk of breast cancer.

Nurses may find it is helpful to refer to the sections in the nutrition and physical activity guidelines (Kushi et al., 2012) that refer to other aspects of food intake relating to prevention of cancer. They include more specific suggestions for particular cancers, evidence specific to nutrient supplementation, and answers to other frequently asked questions. It is available free for download (subject to copyright if used) at http://onlinelibrary.wiley.com/doi/10.3322/caac.20140/full.

Osteoporosis

Epidemiology

Osteoporosis, a bone disease characterized by low bone mass leading to fragile bones and an increased risk of hip, spine, and wrist fractures, is a major public health risk for an estimated 44 million individuals in the United States, or 55% of people aged 50 years or older (National Osteoporosis Foundation, 2011). Osteoporosis has already been diagnosed in 10 million people, and 34 million more people have low bone mineral density or osteopenia, placing them at increased risk of osteoporosis. Of the 10 million Americans estimated to have osteoporosis, 80% are women and 20% are men. Of those with hip fractures, 24% die within a year, men twice as often as women and black American women more often than Caucasian women. Direct financial expenditures for management of osteoporotic fracture alone were estimated at $19 billion in 2005 and will likely rise to approximately $25.3 billion by 2025. These figures underestimate significantly the true costs of osteoporosis because they fail to include the costs of treatment for individuals without a history of fractures or the indirect costs of lost wages or productivity of either the individual or the caregiver.

The National Osteoporosis Foundation recognizes the following risk factors for osteoporosis:

- Older age: as age increases, risk increases
- Female gender
- Personal history of osteoporosis or fracture as an adult
- Family history of osteoporosis or broken bones
- Low levels of sex hormones: in women, early estrogen deficiency (younger than 45 years) or low estrogen levels during menopause, missing periods (amenorrhea); in men, low levels of testosterone and estrogen
- Diet: low in calcium or vitamin D intake; high intake of protein, sodium, and caffeine
- Sedentary lifestyle

- Use of oral corticosteroid therapy for 3 months or more
- Smoking (active or passive)
- High alcohol intake (three or more drinks per day)
- Specific medications (steroids, some anticonvulsants, and other medications)
- Some diseases and conditions (anorexia nervosa, rheumatoid arthritis, gastrointestinal diseases, including celiac disease, sickle cell anemia, and lupus).

Although the prevalence of osteoporosis and the incidence of fracture differ by sex and race/ethnicity, there is a significant risk for all groups even with differences in bone mass density. The latest available facts (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2012a, 2102b) indicate that an estimated 20% of non-Hispanic Caucasian/Asian women, 10% of Hispanic women, and 5% of non-Hispanic black women 50 years or older currently have osteoporosis. Low bone density is even higher in the same groups: 52%, 49%, and 35% respectively. Currently, risk is rising most rapidly in Hispanic women although the reasons are unknown. Among men 50 years or older, an estimated 7% of non-Hispanic Caucasian/Asian men, 4% of non-Hispanic black men, and 3% of Hispanic men have osteoporosis. Low bone density is higher in the same groups: 35%, 19%, and 23% respectively (National Institute of Arthritis and Musculoskeletal and Skin Diseases, 2012a, 2012b). As there is limited information on other ethnic/racial groups, the data are not included.

Pathophysiology

Osteoporosis develops slowly, resulting in loss of bone mass and fractures, especially in the wrist, hip, and spinal areas. It is defined as a skeletal disorder characterized by compromised bone strength predisposing to an increased risk of fracture. Bone strength reflects the integration of two main features: bone density and bone quality. Bone mineral density is expressed as grams of mineral per area or volume and, in any given individual, is determined by peak bone mass and amount of bone loss. Bone quality refers to architecture, turnover,

damage accumulation (microfractures), and mineralization. Osteoporotic bone fractures more easily than healthy bone; as such, osteoporosis is a significant risk factor for fracture.

Factors involved in building and maintaining skeletal health throughout life.

The bone mass attained early in life, 85% to 90% of which is reached by age 18 years for girls and age 20 years for boys, is perhaps the most important determinant of lifelong skeletal health. Individuals with the highest peak bone mass after adolescence have the greatest protective advantage when there is a decline in bone density with increasing age, illness, and diminished sex steroid production.

Genetic factors exert a strong and perhaps predominant influence on peak bone mass, but physiological, environmental, and modifiable lifestyle factors can also play a significant role. Among these factors are adequate nutrition and body weight, the sex hormones of puberty, and physical activity (particularly weight-bearing activity). Therefore maximizing bone mineral density early in life presents a vital opportunity to reduce the effect of bone loss related to aging. Childhood is a critical time for development of lifestyle habits conducive to maintaining good bone health throughout life. Additionally, cigarette smoking, which may start in adolescence, may have a deleterious effect on bone mass.

Prevention

Once thought to be a natural part of aging among women, osteoporosis is no longer considered age or sex dependent and is largely preventable, thanks to the recent progress in the understanding of its causes, diagnosis, and treatment. Optimization of bone health is a process that must occur throughout the life span in both men and women so as to prevent osteoporosis. Calcium and vitamin D are the nutrients most important for attaining peak bone mass and for preventing and treating osteoporosis. Although it is difficult to obtain an adequate amount of calcium from food sources, the alternative use of supplements is in question as there is no

apparent evidence that they prevent fractures as well as dietary sources (Bolland et al., 2015).

A healthy diet, adequate in calories and appropriate nutrients, is essential for normal growth and development of all tissues, including bone. Table 11-4 suggests dietary calcium (and vitamin D) intake recommendations for various stages of life. Factors contributing to low calcium intake include restriction of consumption of dairy products because of food preferences or lactose intolerance, a generally low level of fruit and vegetable consumption, and a high intake of low-calcium beverages such as soft drinks. Lactose and vitamin D enhance calcium absorption, as does as an acidic environment, seen in superior absorption in calcium-enriched orange juice. Calcium is well absorbed from dairy foods, which are also the only source of lactose that enhances absorption.

TABLE 11-4

Dietary Reference Intakes for Calcium and Vitamin D

Calcium				Vitamin D		
Life Stage Group	**EAR (mg/day)**	**RDA (mg/day)**	**UL (mg/day)**	**EAR (IU/day)**	**RDA (IU/day)**	**UL (IU/day)**
Infants from birth to 6 mo	—	—	1000	—	—	1000
Infants from 6 to 12 mo	—	—	1500	—	—	1500
1–3 yr	500	700	2500	400	600	2500
4–8 yr	800	1000	2500	400	600	3000
9–13 yr	1100	1300	3000	400	600	4000
14–18 yr	1100	1300	3000	400	600	
19–30 yr	800	1000	2500	400	600	4000
31–50 yr	800	1000	2500	400	600	4000
51–70 yr men	800	1000	2000	400	600	4000
51–70 yr women	1000	1200	2000	400	600	4000
>70 yr	1000	1200	2000	400	800	4000
14–18 yr, pregnant or lactating	1100	1300	3000	400	600	4000
19–50 yr, pregnant or lactating	800	1000	2500	400	600	4000

EAR, Estimated average requirement; *RDA*, recommended dietary allowance; *UL*, tolerable upper intake level.

From Food and Nutrition Board, Institute of Medicine. (2011*). Dietary reference intakes for calcium and vitamin D.* Washington, DC: National Academies Press.

Vitamin D is a fat-soluble vitamin encompassing two molecules—vitamin D2 (ergocalciferol) and vitamin D3 (cholecalciferol). Vitamin D3 is the form of vitamin D that best supports bone health. It is synthesized in the body when the skin is exposed to the ultraviolet rays of the sun. This process is complicated by various concerns about sunscreens, clothing, and weather changes. Vitamin D from foods, as well as that from sun exposure, then undergoes a complicated metabolic pathway through the liver and the kidneys, emerging as the hormone 1,25-dehydroxyvitamin D_3, the active form. Vitamin D is commonly added to milk, and other food sources of vitamin D include fatty fish (salmon and mackerel); fortified margarine; eggs; and some fortified, ready-to-eat cereals. Some studies are questioning whether or not most infants and young children in the United States are getting adequate calcium and vitamin D intakes. Black and colleagues (2014) concluded that the overall dietary intake of children consuming a usual diet makes it impossible to meet the vitamin D recommendations of the Institute of Medicine, Food and Nutrition Board (2011). During adolescence, when consumption of dairy products decreases, vitamin D intake is likely to be inadequate, which may affect calcium absorption adversely. Other nutrients have been evaluated relative to bone health. High dietary protein, caffeine, phosphorus, and sodium intake may adversely affect calcium balance; however, their effects appear to be offset in individuals with adequate calcium intakes.

Food should be selected to provide adequate calcium intake. Women of all ages should make sure they get adequate calcium intake by consuming more calcium-rich foods, including calcium-fortified foods such as orange juice, milk, and other dairy products as they deliver the most calcium of any food group. Low-fat (1%) and fat-free milk, low-fat yogurt, and low-fat cheeses are the dairy products of choice. Other good sources of calcium include sardines, canned salmon (if the bones are eaten), and some dark green leafy vegetables, especially collard greens. Orange juice and milk fortified with calcium are also good sources, as are soy, almond and rice milks, and other fortified food products. Supplementation with calcium tablets may be

appropriate for high-risk individuals with inadequate calcium intake. However, it is particularly important for older women to be vigilant about their intakes of calcium from dietary sources, supplements, and medications such as antacids because of the risk of exceeding the UL of any age/gender group (National Research Council, 2010). Men may also be wise to limit calcium supplementation and not exceed normal dietary levels because of an association with increased risk of prostate cancer (Kushi et al., 2012).

For those who do choose calcium supplements, calcium carbonate (40% elemental calcium), calcium citrate (24%), calcium lactate (14%), and calcium gluconate (9%) are preferred. (Dolomite and bone meal are not recommended because they may be contaminated with lead.) Calcium supplement absorption is most efficient for individuals with adequate gastric acid production at doses no greater than 500 mg at a time when taken with meals.

Anyone younger than 25 years who ingests less than the recommended DRI for calcium should be urged to develop strategies for increasing it. Children, particularly girls between the ages of 9 and 18 years, are at the highest risk of deficiency (National Research Council, 2010). By modeling appropriate behaviors, health care professionals can help prevent or delay the onset of osteoporosis in themselves, their families, and the people in their care.

Obesity

Overweight (defined in the Body Mass Index Formulas section) can seriously affect health and longevity and is associated with the leading nutrition-related causes of death in the United States: type 2 DM, CVD, and some cancers. Obesity (defined in the Body Mass Index for Adults section) is also associated with gout and gallbladder disease and may contribute to the development of osteoarthritis in the weight-bearing joints.

Epidemiology

Overweight and obesity are found worldwide, and the prevalence of

these conditions in the United States ranks high in comparison with that of other developed nations. As already mentioned, 36.5% of American adults aged 20 years or older are obese. In children, 8.9% of those aged 2 to 5 years were classified as obese and 17.5% of those aged 6 to 11 years were classified as obese, and 20.5% of adolescents aged 12 to 19 years were classified as obese (CDC, 2016a,b). Lifestyle, genetics, hormonal factors, and social-ecological factors are among the many factors contributing to the problem.

Obesity is more common in women than in men. Among men there is a modest ethnic variation in the prevalence of being overweight, the greatest difference occurring between black men (67%) and Hispanic American men (74.6%). Among women the ethnic variation is substantial. Almost 57.6% of white women are overweight, Hispanic American and Puerto Rican women have a greater prevalence of being overweight (73%) than their white counterparts, and more than 79.6% of black women are overweight (National Center for Health Statistics, 2011). Potential contributing factors often associated with the greater propensity for adult black women becoming obese include lower levels of physical activity, higher calorie intake, and lower levels of education and socioeconomic status, as well as broader acceptance of a larger body size within the black American community (Hawkins, 2007; Sanchez-Johnson et al., 2004).

Body Mass Index for Adults

Based on an adult's height and weight, **body mass index** (BMI) is a helpful indicator of underweight, normal weight, overweight, and obesity (USDHHS, 2010b). One can calculate a person's BMI by dividing the person's weight in kilograms by their height in meters squared (http://www.cdc.gov/healthyweight/assessing/bmi).

Body mass index formulas.

BMI may be used as an indicator of body fat, but it cannot be interpreted as a specific percentage of body fat. Age and sex influence the relationship between fat and BMI. For example, women are more likely to have a higher percentage of body fat than men have for the

same BMI. As weight is part of the BMI calculation, it must be noted that scale weights may be inaccurate if used universally. For example, a well-trained athlete with a higher proportion of muscle to fat will weigh more because muscle weighs more than fat. By the same token, bone weight differs in people with smaller frames compared with those with larger frames and higher bone density. Additionally, older people have more body fat than do younger adults (Gallagher et al., 2000). BMI is used to screen and monitor a population to detect the risk of health or nutritional disorders. In an individual, other data must be used to determine whether a high BMI is associated with increased risk of disease and death for that person; use of BMI alone is not diagnostic. Waist circumference is a better indicator of the risk of metabolic syndrome. As mentioned previously, the latter identifies several risk factors associated with morbidity such as elevated level of triglycerides, low HDL level, high LDL level, elevated blood glucose level, and elevated blood pressure. For more details, see USDHHS (2010b).

BMI ranges are based on the effect body weight has on disease and death. A BMI from 19 to 25 kg/m^2 is a healthy target range for adults. BMIs higher than 25 kg/m^2 are associated with increased risks of developing CVD, gallbladder disease, high blood pressure, and non–insulin-dependent DM (type 2 diabetes).

BMIs for adults are expressed by one number, regardless of age or sex, using the following guidelines established by the World Health Organization (2006):

- Underweight: BMI less than 18.5 kg/m^2
- Healthy weight: BMI of 18.5 to 24.9 kg/m^2
- Overweight: BMI of 25 to 29.9 kg/m^2
- Class 1 obese: BMI of 30 to 34.9 kg/m^2
- Class 2 obese: BMI of 35 to 39.9 kg/m^2
- Class 3 obese (morbid obesity): BMI of 40 kg/m^2 or higher

Body Mass Index Growth Charts for Children

Pediatric health care providers have used growth charts since 1977, with the newest ones released in 2000 by the CDC to more accurately reflect the nation's cultural and racial diversity. To track growth and development in children and adolescents through age 20 years, pediatricians, nurses, and nutritionists use charts widely to assist in signaling potential developmental and weight problems earlier in childhood/adolescence. They consist of a series of percentile curves that illustrate the distribution in growth of children across the United States.

The BMI is an early warning signal that is helpful as early as age 2 years to help identify children who have the potential to become overweight. Early identification of obesity risk gives parents the opportunity to modify their family eating and activity patterns before their children develop a weight problem.

The CDC's charts are based on data gathered through the NHNES, the only survey that collects data from actual physical examinations on a cross-section of Americans from all over the country. This survey shows that since the 1980s the number of overweight children and adolescents has doubled. The growth charts indicate that, in general, children are heavier today than in 1977, but height has remained virtually unchanged. The charts are available on the CDC website at http://www.cdc.gov/growthcharts.

Diet Intervention in Weight Reduction

With the advances in **nutritional genomics** it may be possible to individualize dietary recommendations on the basis of a person's genotype, thus having a greater impact on risk reduction in diet-related diseases such as obesity (Box 11-7: Genomics). A balanced diet to support weight reduction should include appropriate **serving sizes** to meet individual nutrient needs. Additionally, exercise is particularly important from the outset, because with exercise there is less need to restrict food intake. Exercise also favors long-term maintenance of body weight (as described in Chapter 12).

Box 11-7

Genomics

Nutritional Genomics[a]

The relatively new field of nutritional genomics is a multidisciplinary field of research that investigates the effects a person's diet has on that person's genes (i.e., nutrigenomics) and how our genetic variations dictate our response to certain nutrients (i.e., nutrigenetics). It has long been accepted that slight variations in our genetic makeup account for the individuality of our physical appearances. Think about how you guess at what your height potential will be. We generally look to our biological parents for answers regarding our physical appearance. Likewise, the study of nutritional genomics is attempting to predict how a specific genetic identity will influence a person's response to food and the nutrients within it.

There are many examples of how such individual genetic variants alter disease treatment in health care. For example, two people with hypertension may need different medications to treat the same condition because of their biological response to certain medications. It stands to reason then that the same two people may also benefit from different dietary interventions. Obesity is one of the primary health concerns in the United States and is a significant risk factor for all other major chronic diseases. Nutritional genomics makes possible the use of personalized diet prescription based on an individual's specific genetic profile. Researchers believe that the potential for personalized dietary intervention could drastically change the prevalence of chronic disease, particularly that of obesity (Huang et al., 2015). If such diet therapies are more effective in managing or preventing disease, this will allow health care to focus more on health promotion instead of disease management. Such a shift in health care represents a significantly more sustainable and cost-effective strategy to enhance the health of the nation.

For additional information regarding nutritional genomics, refer to

the website of the Center of Excellence for Nutritional Genomics at the University of California, Davis: http://nutrigenomics.ucdavis.edu.

[a]With contribution from Staci Nix.

From Huang, T., & Hu, F. B. (2015). Gene-environment interactions and obesity: Recent developments and future directions. *BMC Med Genomics, 8*(Suppl 1), S2.

Nurses make referrals to supervised or unsupervised programs as appropriate. People expect this type of advice on maintaining their health. Therefore nurses can play an important role, although not supervising individuals' weight loss efforts directly. For more information on obesity among adults, see the *Solving the Problem of Childhood Obesity Within a Generation: The White House Task Force on Childhood Obesity Report to the President* (White House Task Force Report on Childhood Obesity, 2010), *The Surgeon General's Vision for a Healthy and Fit Nation* (USDHHS, 2010b), and *Recommended Community Strategies and Measurements to Reduce Obesity in the United States* (Khan et al., 2009).

There are many positive effects of only relatively small amounts of weight loss (5% to 10% of body weight) for people who are obese, including the following:

- Decreased blood pressure (decreased risk of a heart attack and stroke)
- Reduced abnormally high levels of blood glucose associated with diabetes
- Reduced elevated levels of cholesterol and triglycerides associated with CVD
- Reduced sleep apnea (irregular breathing during sleep)
- Decreased risk of osteoarthritis in the weight-bearing joints
- Decreased depression
- Increased self-esteem

The acronym LEARN has been suggested as a mnemonic device for

health professionals. LEARN refers to the steps nurses can take to help the person who needs to improve health-related behavior (Brownell, 2000). LEARN is particularly useful as a guideline for communicating with the clinically obese individual who has indicated dissatisfaction with his or her current weight:

L—Listen with sympathy and understanding to the person's perception of the problem.

E—Explain personal perceptions of the problem.

A—Acknowledge and discuss differences and similarities.

R—Recommend treatment.

N—Negotiate an agreement.

In 1998 an NIH-sponsored technical support conference identified the following characteristics of voluntary weight loss and weight control in the United States (USDHHS, 2010b):

- Obesity is a chronic disease.
- Obesity has many causes.
- Cure is rare; palliation is realistic.
- Weight loss is slow.
- Recidivism is common.
- Weight regain may be slow, but it is often rapid.
- Management is often more frustrating than the underlying disease.

The conference noted significant adverse effects for obese dieters who regain lost weight:

- Repeated weight gain and loss may have adverse psychological and physical effects; for example, evidence suggests that mildly to moderately overweight women who are dieting may be at risk of binge eating.
- Although data on the health effects of repeated weight gain and loss

(weight cycling) are also inconclusive, weight cycling appears to affect energy metabolism and may cause faster regaining of weight.

- Depression and decreased self-esteem occur.

These findings paint a bleak outlook that one should share with caution when advising individuals.

Fad diets do not provide the best way to lose weight and should be avoided. However, recognizing that people will do almost anything to lose weight when desperate, it is helpful to be able to discuss current fads intelligently and to guide individuals as needed. The new prevention-focused model of health care, mentioned earlier, includes many facets needed to avoid and treat obesity among adults and children in the United States. On an individual basis, for people who cannot or do not choose to maintain a BMI less than 30 kg/m^2 as a priority, the paradigm *Health at Any Size* (Spark, 2001) is described in Box 11-8.

Box 11-8

Health at Any Size

The Size Acceptance Nondiet Movement

This paradigm (Spark, 2001) has replaced the question "How can fat people lose weight?" with the question "How can fat people be healthy?" The following tenets are the foundation of the movement:

- Good health is a state of physical, mental, and social well-being. People of all sizes and shapes can reduce their risk of poor health by adopting a healthy lifestyle, which includes eating a variety of healthy foods, being physically active because it is fun and feels good, and appreciating the body as it is.

- Human beings come in a variety of sizes and shapes; size diversity is a positive characteristic of the human race. Respect the bodies of others, although they might be quite different.

- There is no ideal body size, shape, BMI, or body composition that every individual should strive to achieve.
- Self-esteem and body image are strongly linked. Helping people feel good about their bodies and about who they are can help motivate them to maintain healthy behaviors.
- People are responsible for care of their own bodies.
- Appearance stereotyping is wrong. Their weight notwithstanding, all people deserve to be treated equally in the job market and on the job, to be treated equally in the media, and to receive competent and respectful treatment by health care professionals.

How to Become a Size-Sensitive Health Professional

- On the intake form, include a question asking whether the person is satisfied with his or her body size. If the answer is “yes,” then try to avoid the issue in the future.
- When the person asks not to be weighed, the request is acknowledged without complaint and automatically taken into account on follow-up office visits. (There are a few cases in which weighing is necessary, such as when certain medications, chemotherapy, or anesthetics are administered.)
- A size-sensitive health care professional does not necessarily avoid mentioning weight but should avoid making an issue of weight, avoid lectures and humiliation, and respect the individual's wishes with regard to weight discussions.
- When weight contributes to a problem, the professional mentions this situation but also considers other diagnoses and recommends tests to determine the actual diagnosis when appropriate. If weight loss is a recommended treatment for a problem, the compassionate professional may mention this, but at minimum, and recommend

and prescribe other treatments. Accept the individual's wish not to use weight loss as a treatment.

- Some health care professionals believe that overweight and obesity are not necessarily unhealthy. However, other professionals who believe that fat is unhealthy may acknowledge that weight loss is usually ineffective or that individuals have the right to direct their own treatment.

- Ideally, the waiting area, examining suite, and consultation room are equipped with armless chairs, large blood pressure cuffs, large examination gowns, and other equipment suitable for large people. If this is not the case, then the office staff acknowledges the importance of these items when told.

From Spark, A. (2001). Health at any size: The size acceptance nondiet movement. *Journal of the American Medical Women's Association*, *56*(2), 69–72.

FDA-approved weight loss medication can play a helpful role in assisting individuals to lose weight and keep it off. As of early 2012, currently orlistat (also available as Xenical by prescription or Alli over-the-counter) is the only approved general weight loss drug. It is important to help those using it to recognize the warning signs and see a health provider if they have negative symptoms. Other non–FDA-approved weight loss supplements that are available are generally not recommended because of safety concerns.

Diabetes

Prevalence and Incidence

Diabetes is becoming more prevalent, especially type 2 diabetes, which is associated with obesity. The numbers of existing cases **(prevalence)** and new cases **(incidence)** were increasing between 1990 and 2008, but there has been a possible decrease in diabetes incidence since 2008 (Herman & Rothberg, 2015). The CDC's diabetes maps appear to be mirroring the trends seen in state obesity maps. An

estimated 25.8 million Americans (8.3% of the US population) had the disease in 2010 (CDC, 2011b). Among those, older adults and minorities were disproportionately affected. Almost 27% (or 10.9 million) of adults 65 years or older have diagnosed diabetes. After adjustment for population age differences, 2007 to 2009 national survey data of adults (aged 20 years or older) showed the risk of diagnosed diabetes. When compared with non-Hispanic white adults, the risk was 18% higher among Asian Americans, 66% higher among Hispanics, and 77% higher among non-Hispanic black Americans. It was about the same for Cubans, Central Americans, and South Americans, 87% higher for Mexican Americans, and 94% higher for Puerto Ricans. In the Native American population, just among those served by the Indian Health Service, the prevalence is almost twice the national average. Rates differ by region, ranging from 5.5% among Alaska Native adults to 33.5% among Native American adults in southern Arizona.

DM accounts for 90% to 95% of all diagnosed cases of diabetes. The risk factors include the following: having **pre-diabetes** (impaired glucose tolerance and/or impaired fasting glucose), being older than 45 years, being overweight or obese, not exercising regularly, having a family history of diabetes or a personal history of gestational diabetes, or giving birth to a baby of at least 9 pounds. Other risk factors include high blood pressure, low HDL cholesterol level, high triglyceride level, and certain races or ethnic groups (Nesto, 2005).

Type 2 DM is the seventh leading cause of death among Americans and the leading cause of blindness, kidney failure, and lower extremity amputations; it also greatly increases the risk of a heart attack or stroke. In 2007, diabetes accounted for more than $174 billion in direct and indirect medical costs and lost productivity (CDC, 2011b). Much of the burden of diabetes can be prevented or delayed by early detection, improved delivery of care, and better education on disease self-management (American Diabetes Association, 2012).

Type 2 Diabetes in Children

Although DM in children and adolescents was believed to be

exclusively type 1, type 2 diabetes is now considered a sizeable and growing problem among Native Americans and an emerging public health problem among other North American ethnic groups. The epidemic of obesity among children and adolescents, the decrease in physical activity, the increase in calorie-dense foods, and the exposure to diabetes in utero are likely contributors to the increase in prevalence of type 2 DM in this population. Young children with type 1 DM or type 2 DM who are either overweight or obese should be observed for metabolic syndrome and CVD risk. The adolescent population is at higher risk because of lifestyle implications, smoking, poor diet adherence, etc., that may put them at risk of chronic disease earlier in life. Recent studies suggest that renal and CVD disease risk is approximately twice that of youth with type 1 DM (Wong et al., 2015).

Although some children and adolescents are symptomatic, others do not enter the clinical arena until they have severe ketoacidosis and may have a transient insulin requirement. Diabetic complications (**dyslipidemia** and hypertension) have been observed among Pima Indians as early as the teenage years. No evidence-based guidelines for treatment of type 2 diabetes in children and adolescents are available, and oral agents have not been tested or approved for this age group. Generally, children and adolescents with type 2 DM have poor glycemic control. Population mobility, lack of symptoms, denial of illness, absence of family support, and inadequate health care insurance coverage have all been identified as major barriers to adherence to treatment and follow-up and to successful clinical management. Because of a longer duration of disease (from earlier onset), and because glucose control and adherence are challenging during the teenage years, the lifetime complications (microvascular and macrovascular diseases and decreased quality of life) in this population will probably be considerable (Fagot-Campagna et al., 2000).

Diet Intervention

Medical nutrition therapy (MNT) is the most critical and pivotal

component of diabetes care. At the minimum, MNT involves the team efforts of a physician, a registered nurse, a registered dietitian, and, in some practice settings, a mental health professional. The purpose of MNT for people with type 2 DM is to delay or prevent the development of complications (blindness, CHD, nephropathy, and neuropathy). No single diabetic diet or American Diabetes Association diet exists. The recommended diet can be defined only as a nutrition prescription based on assessment, treatment goals, and outcomes. Nutrition advice for people with type 2 diabetes is essentially the same as that for the general population: follow the *Dietary Guidelines for Americans.* MNT for people with diabetes should be individualized, with consideration given to usual eating habits, culture, and other lifestyle factors. Nutrition recommendations are then developed and implemented to meet treatment goals and desired outcomes. Monitoring metabolic parameters, including blood glucose levels, glycosylated hemoglobin (HbA1C) levels, lipid values, blood pressure, body weight, renal function (when appropriate), and quality of life, is crucial to ensure successful outcomes. Monitoring HbA1C to less than 6.5% or 7% in most current guidelines is not always the only criterion to use. More importantly the treatment should be started early to prevent further destruction of the beta cells of the pancreas that produce insulin. Studies show that even in people with pre-diabetes or diabetes there is a loss of 50% to 80% of their beta cells (Aguilar & Zonszein, 2015). The American Diabetes Association further recommends ongoing nutrition self-management education for these individuals.

For people with **hyperglycemia, hyperlipidemia,** obesity, or suboptimal nutrition, start with this nonpharmacological management:

- Determine an appropriate, tailored meal plan based on energy needs for body weight goals (moderate weight loss, weight maintenance, weight gain). With that data, the determination is made with regard to serving sizes and numbers with use of MyPlate. For children and adolescents, their growth needs must be accounted for as well.
- Encourage regular exercise.

- Evaluate the individual with use of the outcome measures listed in Table 11-5. People who have been counseled regarding diet and exercise but who have not responded satisfactorily after 4 to 6 weeks should be referred to a registered dietitian who is a diabetes educator. Those with acute complications, such as hypoglycemia, exercise-related problems, renal disease, autonomic neuropathy, hypertension, or CVD, must first see a physician.

TABLE 11-5

Goals and Recommendations of Medical Nutrition Therapy for Individuals With Type 2 Diabetes

Index	Goal	Recommendation
HbA1c	*For diagnosis must have:* ≥6.5% with a method that is NGSP certified and standardized to DCCT assay	The HbA1c test is the preferred test to diagnose diabetes in nonpregnant adults; other tests listed below may also be used
FPG	≥126 mg/dL (7.0 mmol/L) Fasting is defined as no calorie intake for at least 8 h	The FPG test detects diabetes and pre-diabetes. It is most reliable when done in the morning
2-h plasma glucose	≥200 mg/dL (11.1 mmol/L) during OGTT	May also be used with a WHO-approved method and a glucose load of 75 g of anhydrous glucose dissolved in water
Random plasma glucose	≥200 mg/dL (11.1 mmol/L)	In people with classic hyperglycemia or hyperglycemic crisis
HbA1c	A reasonable HbA1c goal for many nonpregnant adults is <7%; individualize to ≤6.5% or up to 8% depending on factors such as the level of hypoglycemia, life expectancy, duration of disease, and level of CVD	Perform HbA1c test at least twice a year in individuals who are meeting treatment goals and who have stable glycemic control Lowering of HbA1c fraction is associated with reduction of microvascular complications of diabetes and possibly macrovascular disease
Weight change	For most overweight/obese people (BMI <35 kg/m^2) recommend modest weight loss (5–7% of body weight)	Modest weight loss has been shown to reduce insulin resistance
MNT	Individuals who have pre-diabetes or diabetes should receive individualized MNT as needed to achieve treatment goals, preferably provided by a registered dietitian familiar with components of diabetes MNT; meet body's daily nutritional needs and minimized risk of chronic disease	Structure the program to emphasize lifestyle changes, including education and regular physical activity Modify macronutrient composition to individual and medical condition while meeting DRIs for micronutrients; a variety of meal patterns work (Mediterranean, a lower-fat, lower-carbohydrate pattern, or vegetarian); saturated fat intake should be <7% of total calories; intake of trans fat should be minimized
Physical activity	If there are no medication limitations, physical activity distributed over at least 3 days per week with no more than 2 consecutive days without physical activity; encourage the person to perform resistance	Physical activity level gradually increased and sustained at target goal To improve glycemic control, assist with weight maintenance, and reduce risk of CVD, at least 150 min of moderate-intensity aerobic physical

	training at least twice per week	activity per week (50–70% of maximum heart rate)

From American Diabetes Association. (2012). Standards of medical care in diabetes. *Diabetes Care, 35*(1), S11–S63.

A nutrition prescription, which is done after the physician has completed a physical and medical assessment, may be general, but it should reflect the individual's therapy goals. The following are some sample orders the nurse might write for the dietitian:

- Individualized diabetic meal plan to achieve clinical goals of diabetes MNT
- MNT to achieve blood glucose levels as near normal as possible
- Individualized meal plan to decrease diabetes control and blood lipid levels
- Diet for improved glycemic control and blood pressure measurements

The registered dietitian with a summary of the planned nutrition intervention may define the prescription further. For example, the dietitian might write:

- Weight-reduction meal plan based on general eating guidelines, 1200 to 1500 calories, three meals, and one snack
- 2300 mg sodium meal plan with weight maintenance
- Carbohydrate-counting meal plan, adjusting carbohydrate and meal timing to achieve target glucose goals

Human Immunodeficiency Virus/Acquired Immunodeficiency Syndrome

Epidemiology

According to the CDC in 2011, 1.2 million adults and adolescents in the United States were infected with HIV, more than ever before

(CDC, 2016c). In 2015, approximately 40,000 people were diagnosed with HIV: the number of new diagnoses decreased 19% from 2005 to 2014. This represents a true decline in cases (CDC, 2016c). Whereas HIV infection can be diagnosed earlier in many more people, still as many as one-third wait until it is too late for effective prevention or treatment and advance to AIDS within 12 months of diagnosis. AIDS has been diagnosed in just more than 1 million people, since the beginning of the epidemic (CDC, 2016c).

Diet Intervention

Attention to nutrition in early HIV intervention is essential for several reasons. People can now live for decades with HIV/AIDS as long as HIV/AIDS is diagnosed early and they are treated early. Even for those people who are HIV positive but in whom HIV infection is diagnosed late, it may still take up to 1 year before most will progress to AIDS. Nutritious diets can improve the sense of well-being, minimize disease symptoms and the side effects of medications, and reduce the risk of opportunistic infections. For people who are asymptomatic, following the *Dietary Guidelines for Americans* recommendations for meal planning and food safety is suggested. Implementation of good dietary habits early in the disease may have benefits for end-stage developments such as severe weight loss. The person who receives a diagnosis of being HIV positive usually becomes depressed. Depression can lead to loss of appetite; therefore attention to nutrition is critical as soon as a diagnosis is made.

An initial nutritional assessment suggesting the extent to which nutrition counseling is needed and providing valuable baseline information for evaluation of the progression of the disease is necessary (American Dietetic Association, 2010b). Involving the person's significant others in early discussions of optimal nutrition and food safety is important. A nutrient-dense, protein-rich, well-balanced diet in line with the *Dietary Guidelines for Americans 2015–2020* should be stressed but should also include a vitamin and mineral supplement. Evidence suggests that micronutrient deficiencies are common (zinc, iron, selenium, and vitamin B12) and that those

affected individuals not taking vitamin supplementation have increased morbidity and mortality (American Dietetic Association, 2010b). Fair evidence also shows that people with HIV infection and their caregivers do not understand how to best avoid food-borne illness. Giving them practical tips, as well as reasons to avoid certain foods, is helpful (Hoffman et al., 2005). Because of a compromised immune system, illness in people with HIV/AIDS will become worse when they are exposed to food-borne organisms.

The aims of nutrition therapy and counseling specifically for asymptomatic persons who have HIV/AIDS are individualized and based on the following criteria:

- Determine how the person appeared physically before becoming HIV positive. Was the person obese or heavily muscled? Was the person inactive or athletic? Was the person eating a balanced diet high in vitamins and minerals?
- Determine the calorie intakes necessary to achieve or maintain a healthy weight.
- Determine that the protein is of high quality to help maintain or gain healthy muscle mass.
- Determine what the person knows about nutrition and its effect on the disease as well as food and water safety.
- Determine the person's knowledge of the use of food to ease some of the gastrointestinal side effects of medications.
- Determine the person's understanding of the importance of maintaining eating and medication schedules to ensure maximal absorption of medication.

Assess current knowledge when the individual has diabetes or dyslipidemia, and refer the person as appropriate for teaching about how to manage these conditions within the context of HIV/AIDS.

Breastfeeding should be avoided to prevent vertical transmission of HIV from the mother to the child. This objective is fairly easy to implement in the United States, which has a long history of safe breast milk substitutes in the form of milk-based and soy-based infant formulas. In many developing countries, however, the risks attached

to feeding an infant with something other than breast milk are greater than the 20% risk of vertical transmission of the virus that causes AIDS.

Case Study

Obesity/Overweight: Estella

Estella is a 34-year-old Hispanic single mother of three children sharing a small apartment with her 68-year-old mother in inner-city Los Angeles. She is a full-time laborer in a local manufacturing facility and attends night classes to obtain her medical assistant's license. She is receiving some government assistance but is raising her children, aged 4, 7, and 10 years, on a meager income. Most days she arrives home too tired to prepare a well-balanced meal for her family and admits to eating a lot of fast food. Her mother, despite declining vision, works part-time on evenings at a local fast food restaurant to help with financial difficulties. Her mother is responsible for most of the preparation of meals. Their diet consists mainly of inexpensive carbohydrates: flour tortillas, breads, pasta, cheese, and potatoes. The family budget does not allow for much fresh fruit or vegetables or expensive meats; therefore bologna and hot dogs are frequently served.

Estella has recently been hired at a county hospital as a nursing assistant. A required preemployment physical examination revealed several health risks. At 5 feet, 4 inches, she weighs 185 pounds. Her resting heart rate and blood pressure are also above normal levels. She has a family history of diabetes and heart disease: her father died of a heart attack at age 55 years, and her mother has diabetes that requires daily insulin injections. She was referred to her primary care physician, who recommended immediate lifestyle changes, including walking 30 minutes per day, 4 to 5 days per week, as well as dietary counseling.

Reflective Questions

- What is Estella's understanding of healthy eating?
- How can learning about simple changes in her eating habits affect Estella's weight and risk of type 2 diabetes?
- What local resources promote inexpensive programs to help Estella lose weight?

Care Plan

Obesity/Overweight: Estella

***NURSING DIAGNOSIS: Alteration in current weight related to diet modification and weekly monitoring**

Defining Characteristics

- Single mother works full-time and attends night school. Is raising three children and supporting her mother on a limited income. Income falls into poverty level for family of five.
- Is a divorced woman with limited support system and resources.
- Current weight is 185 pounds at 5 feet, 4 inches tall (84.1 kg, 162.6 cm). Her BMI is 31.8 kg/m^2, including her in the obesity category.
- Resting blood pressure is 164/87 mm Hg, and pulse rate is 88 beats/min.
- Father died at age 55 years of a massive heart attack.
- Mother is overweight and has type 1 diabetes and high blood pressure.
- Diet consists of processed foods and a high-fat diet with little fresh fruit or vegetables.

- Recent job change requires her to be on her feet, walking, lifting, and transporting care recipients.
- Inner-city neighborhood is unsafe to walk in alone or allow her children freedom to play outdoors.
- Single mother of three small boys; she realizes the need to improve her own health to be able to care for and enjoy her children.

Expected Outcomes

- Estella's overall health will improve through reduction of all of the following: weight, BMI, resting pulse rate, and blood pressure.
- Establish realistic goals with Estella to improve quality of meals on a limited income.
- Develop a realistic exercise plan that is inexpensive and not time-consuming.

Interventions

- Teach meal planning strategy to include *Dietary Guidelines for Americans* basic recommendations for a healthy diet and (as deemed appropriate) refer Estella to a certified diabetes educator or registered dietitian if resources permit.
- Teach Estella easy menus to prepare that use more whole grains, fruits, and vegetables and less processed or fast food. (Resources might include the USDA's Center for Nutrition Policy and Promotion's *Recipes and Tips for Healthy, Thrifty Meals;* https://www.cnpp.usda.gov/sites/default/files/usda_food_plans_cos
- Encourage a regular exercise program, beginning with a walking program of 30 minutes per day, four to five times per week. Gradually increase the pace and distance to intensify aerobic

benefits.

Investigate safe options, such as a neighborhood YMCA or park program, for family activities; refer to SNAP or WIC as appropriate; or offer other community resources such as Share Our Strength's Cooking Matters (http://cookingmatters.org/) courses for low-income adults and children.

Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

This chapter has introduced a wide range of subjects, including the *Healthy People 2020* and *Dietary Guidelines for Americans 2015–2020* nutrition objectives, the most current diet recommendations to reduce the risks of developing nutrition-related diseases, FDA regulations for food labeling, government nutrition assistance programs for poor and older Americans, and primary and secondary prevention strategies related to the most common nutrition-related chronic diseases. Many more primary prevention strategies are being discussed as an adjunct to secondary prevention in an effort to make all strategies more successful. Together these topics form the basis of what is known as preventive nutrition, a requisite for the promotion of the nation's public health. All the topics examined in this chapter can be studied further through use of the Internet. High-quality, up-to-date materials and continuing nutrition education literature for professionals are free and on-line.

Exercise

Kevin K. Chui, Frank Tudini, Sheng-Che Yen

OBJECTIVES

After completing this chapter, the reader will be able to:

- Explain the physical activity and fitness goals of *Healthy People 2020,* and the progress made toward these goals.
- Describe how physical activity positively influences physical and psychological health.
- Identify the benefits of physical activity throughout the aging process.
- Evaluate the prescriptions for and benefits of daily physical activity, aerobic exercise, and resistance training.
- Explain the interventions to promote exercise adherence and compliance.

KEY TERMS

Aerobic exercise

Anaerobic exercise

Arthritis

Borg scale

Cardiorespiratory fitness

Cool-down period

Cross-training

Exercise

Exercise prescription
Fat mass
Fibromyalgia syndrome
Flexibility
Low back pain
Muscular fitness
Obesity
Osteoporosis
Physical activity
Physical fitness
Relaxation response
Resistance training
Rheumatoid arthritis
Tai chi
Warm-up period
Yoga

Think About It

Knowing Versus Doing

Having knowledge of the benefits of exercise does not correlate well with long-term exercise compliance. Confidence in the ability to exercise and a sense of the meaning and purpose (core desire) of exercise in life ensure better success.

- What motivates an individual to put the effort into developing and maintaining an active lifestyle?
- Why is being active and physically fit important?

Regular physical activity and exercise enhance both physical and psychological health. Generally, people who exercise regularly, or those who naturally include physical activity in their daily routine, feel better mentally and physically, improve their health profiles, and safeguard their functional independence as they go through the aging process. A holistic approach to physical activity involves exercise for cardiorespiratory health (endurance), exercise for musculoskeletal health (strength, flexibility, and bone density), and body awareness. Body awareness and mindfulness during exercise facilitate self-inquiry and self-acceptance, helping to relieve psychological stress and preventing physical injury (Box 12-1). Not only is an active lifestyle an important component of primary prevention but regular physical activity is also an essential modality in the treatment of chronic disease, which establishes the potential for benefit in all aspects of the biopsychosocial and spiritual model of health.

Box 12-1

Health Impact of Physical Activity

- Improves quality of life
- Improves mood and promotes a sense of well-being
- Increases flexibility
- Builds muscle strength
- Increases endurance
- Increases the efficiency of the heart
- Increases bone density
- Helps with weight reduction
- Decreases risk of stroke

- Decreases risk of heart disease
- Decreases risk of diabetes

Defining Physical Activity in Health

To fully understand the *Healthy People 2020* objectives regarding exercise, the following definitions will be used:

Physical activity: body movement that is produced by the contraction of skeletal muscles and that substantially increases energy expenditure; includes transportation and vocational and leisure-time activity. Leisure-time activity can be further categorized into sports, recreational activities, and exercise training (Figure 12-1).

FIGURE 12-1 Some people choose more vigorous types of exercise.

Exercise (exercise training): planned, structured, and repetitive body movement performed to improve or maintain one or more components of physical fitness.

Aerobic exercise: activity that uses large muscle groups in a repetitive, rhythmical fashion over an extended period to increase the efficiency of the oxidative energy-producing system and

increase cardiorespiratory endurance; uses stored adipose tissue as a major fuel source.

Anaerobic exercise: high-intensity, short-duration activity that increases the efficiency of the phosphocreatine and glycolytic energy-producing systems and increases muscle strength, power, and speed of reactivity; uses phosphagens and glucose-glycogen as major fuel sources.

Physical fitness: a set of attributes (**cardiorespiratory fitness**, muscular fitness, and flexibility) that people have or achieve that relates to the ability to perform physical activity without undue fatigue or risk of injury.

Muscular fitness: the strength and endurance of muscles that allows participation in daily activities with low risk of musculoskeletal injury.

Flexibility: adequate muscle length and joint mobility to allow free and painless movement through a wide range of motion (ROM).

Healthy People 2020 Objectives

Unfortunately, only 23% of the adult population performs enough regular, sustained exercise to gain any significant health benefit, and slightly more than 10% of the population exercises at an intensity necessary to promote cardiorespiratory fitness. According to the Physical Activity and Fitness section (focus area) of *Healthy People 2020,* overall 30.3% of adults 18 years or older in 2013 reported no leisure-time physical activity (National Health Interview Survey, Centers for Disease Control and Prevention [CDC], National Center for Health Statistics) (US Department of Health and Human Services [USDHHS], 2010). Furthermore, the percentage of adults who report no leisure-time physical activity differs by race and ethnicity, sex, educational level, geographical location, disability status, age group, and the presence or absence of arthritis symptoms. The tendency to be sedentary, unfortunately, continues to increase with age and affects all the body's systems, such as the cutaneous, cardiovascular, respiratory, gastrointestinal, and urinary systems. As a result of a person being sedentary, the risk of premature morbidity, death, impairment, functional limitation, and disability increases. According to data from the 2013 Behavioral Risk Factor Surveillance System (BRFSS), the percentage of adults who engage in no leisure-time physical activity increases with age: 18.3% for 18 to 24 years, 22.5% for 25 to 34 years, 24.9% for 35 to 44 years, 27.3% for 45 to 54 years, 28.7% for 55 to 64 years, and 33.1% for 65 years or older (CDC, 2016a). The goal of the Physical Activity and Fitness focus area is to "improve health, fitness, and quality of life through daily physical activity" (USDHHS, 2010). In 2008 the USDHHS released the first-ever publication of national guidelines for physical activity, *2008 Physical Activity Guidelines for Americans* (USDHHS, 2008). These guidelines provide an evidence-based approach to assist Americans to improve their health status. They recommend that children and adolescents be active for at least 60 minutes daily and advise adults to perform at least 150 minutes of moderate-intensity activity per week or 75 minutes of vigorous

activity per week. In 2012, only 20.6% of adults met the guidelines for both aerobic and muscle-strengthening activities (CDC, 2017). The importance of physical activity in the nation's health is reflected in the 15 physical activity and fitness objectives (USDHHS, 2010), a number of objectives which now emphasize traditional and nontraditional partnerships. These objectives take into account the demonstrated relationship between physical activity and an improvement in the biological markers associated with health, and they identify the reasons for the trend toward a more sedentary lifestyle. The National Physical Activity Plan has a vision that all Americans will be physically active in all aspects of their life, which includes work and play (National Physical Activity Plan, 2010). Box 12-2: *Healthy People 2020* provides a summary of the updated physical activity objectives set for 2020.

Box 12-2

Healthy People 2020

Objectives for Physical Activity

- Reduce the proportion of adults who engage in no leisure-time physical activity.
- Increase the proportion of adults who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.
- Increase the proportion of adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.
- Increase the proportion of the nation's public and private schools that require daily physical education for all students.
- Increase the proportion of adolescents who participate in daily

school physical education.

- Increase regularly scheduled elementary school recess in the United States.
- Increase the proportion of school districts that require or recommend elementary school recess for an appropriate period.
- Increase the proportion of children and adolescents who do not exceed recommended limits for screen time.
- Increase the number of states with licensing regulations for physical activity provided in child care.
- Increase the proportion of the nation's public and private schools that provide access to their physical activity spaces and facilities for all persons outside normal school hours (i.e., before and after the school day, on weekends, and during summer and other vacations).
- Increase the proportion of physician office visits that include counseling or education related to physical activity.
- (Developmental) Increase the proportion of employed adults who have access to and participate in employer-based exercise facilities and exercise programs.
- (Developmental) Increase the proportion of trips made by walking.
- (Developmental) Increase the proportion of trips made by bicycling.
- (Developmental) Increase legislative policies for the built environment that enhance access to and availability of physical activity opportunities.

Physical Activity Objectives: Making Progress

The review of the physical activity data from *Healthy People 2020*

(http://www.healthypeople.gov) provides evidence of the progress that has been made toward achieving the original objectives and the regress that has occurred (National Center for Health Statistics, 2016; USDHHS, 2010).

Improving trends (the percentage of):

- Adults aged 18 years or older who reported no leisure-time physical activity: 36.2% in 2008, 32.3% in 2009, 32.4% in 2010, 31.6% in 2011, 29.6% in 2012, 30.3% in 2013.
- Adults who engage in aerobic physical activity of at least moderate intensity for at least 150 min/wk, or vigorous intensity for at least 75 min/wk, or an equivalent combination: 43.5% in 2008, 47.2% in 2009, 47.1% in 2010, 48.8% in 2011, 50.0% in 2012, 49.9% in 2013.
- Adults who engage in aerobic physical activity of at least moderate intensity for more than 300 min/wk, or vigorous intensity for more than 150 min/wk, or an equivalent combination: 28.4% in 2008, 31.2% in 2009, 31.7% in 2010, 33.1% in 2011, 34.3% in 2012, 34.3% in 2013.
- Adults who perform muscle-strengthening activities on 2 days or more per week: 21.9% in 2008, 22.6% in 2009, 24.2% in 2010, 24.2% in 2011, 23.9% in 2012, 24.1% in 2013.
- Adults who meet the objectives for aerobic physical activity and for muscle-strengthening activity: 18.2% in 2008, 19.0% in 2009, 20.6% in 2010, 20.8% in 2011, 20.6% in 2012, 20.8% in 2013.
- School districts that require regularly scheduled elementary school recess: 57.1% in 2006, 58.9% in 2012.
- School districts that require or recommend elementary school recess for an appropriate period: 61.5% in 2006, 63.3% in 2012.
- Children aged 2 to 5 years who view television, view videos, or play video games for no more than 2 hours a day: 75.6% in 2005 to 2008, 76.2% in 2009 to 2012.
- Physician visits made by all children and adults that include counseling about exercise: 7.9% in 2007, 8.7% in 2008, 9.6% in 2009, 9.2% in 2010.

Worsening or no change in the trend (the percentage of):

- Adolescents who meet current federal physical activity guidelines for aerobic physical activity: 28.7% in 2011, 27.1% in 2013.
- Adolescents who participate in daily school physical education: 33.3% in 2009, 31.5% in 2011, 29.4% in 2013.
- Adolescents in grades 9 through 12 who view television, view videos, or play video games for no more than 2 hours a day: 67.2% in 2009, 67.6% in 2011, 67.5% in 2013.
- Adolescents in grades 9 through 12 who use a computer or play computer games outside school (for nonschool work) for no more than 2 hours a day: 75.1% in 2009, 68.9% in 2011, 58.7% in 2013.
- Children aged 2 to 5 years who use a computer or play computer games outside school (for nonschool work) for no more than 2 hours a day: 97.4% in 2005 to 2008, 97.5% in 2009 to 2012.
- Office visits made by individuals with a diagnosis of cardiovascular disease, diabetes, or hyperlipidemia that include counseling or education related to exercise: 13.0% in 2007, 14.1% in 2008, 15.1% in 2009, 12.3% in 2010.

According to the 2014 *State Indicator Report on Physical Activity* (CDC, 2014), the US national weighted percentage of adults who reported no leisure-time activity is 25.4% (unchanged since the 2010 report), with a low of 16.5% in Colorado and a high of 36.0% in Mississippi. Furthermore, for adults nationally, 51.6% met the 150-minute aerobic activity per week guideline, 31.8% met the 300-minute aerobic activity per week guideline, 29.3% met the muscle-strengthening guideline, 20.6% met both the 150-minute aerobic activity guideline and the muscle-strengthening guideline, and 3.4% usually biked or walked to work. Nationally for youths, from the Youth Risk Behavior Surveillance System (YRBSS) data, 15.2% reported that they did not participate in at least 60 minutes of physical activity on at least 1 day (an improvement from 17.1% reported in 2010), with a low of 10.7% in Montana and Nebraska and a high of 27.7% in the District of Columbia. Furthermore, for youths nationally, 27.1% met aerobic activity guidelines and 29.4% had daily physical education (a decline from 30.3% reported in 2010). However, despite

gains (indicating that the message regarding the benefits of physical activity is reaching some segments of the population), the improvements fall short, and the new goals set for *Healthy People 2020* reflect the work that remains.

The prevalence of obese children, adolescents, and adults has increased in the United States and is considered an epidemic. Children and adolescents (aged 2–19 years) are categorized as being obese if their body mass index (BMI), expressed as weight in kilograms divided by height in meters squared, is equal to or greater than the 85th percentile in age- and gender-specific BMI growth charts. According to results from the NHANES for 2011 to 2014, which is conducted by CDC's National Center for Health Statistics, 17.0% of children and adolescents are obese. By age group, 8.9%, 17.5%, and 20.5% of children and adolescents aged 2 to 5 years, 6 to 11 years, and 12 to 19 years respectively were obese, with the same pattern found in both sexes (Ogden et al., 2015). Between 1999 to 2000 and 2013 to 2014, there was a significant increase in obesity in children and adolescents; however, there was no significant increase between 2003 to 2004 and 2013 to 2014: 13.9% in 1999 to 2000, 15.4% in 2001 to 2002, 17.1% in 2003 to 2004, 15.4% in 2005 to 2006, 16.8% in 2007 to 2008, 16.9% in 2009 to 2010, 16.9% in 2011 to 2012, and 17.2% in 2013 to 2014 (Ogden et al., 2015).

Adults, those aged 20 years or older, are considered overweight if their BMI is 25.0 to 29.9 kg/m^2, obese if their BMI is 30.0 kg/m^2 or higher, and extremely obese if their BMI is 40 kg/m^2 or higher. According to data from the NHANES for 2011 to 2014, 36.3% of adults aged 20 years or older were obese (Ogden et al., 2015). The overall prevalence of obesity among women (38.3%) was higher than among men (34.3%). The pattern of obesity for both sexes was similar by age group and was highest (40.2%) among middle-aged adults (40–59 years) and lowest (32.3%) among younger adults (20–39 years), with older adults (60 years or older) falling in the middle (37.0%). Between 1999 to 2000 and 2013 to 2014, there was a significant increase in obesity in adults: 30.5% in 1999 to 2000, 30.5% in 2001 to 2002, 32.2% in 2003 to 2004, 34.3% in 2005 to 2006, 33.7% in 2007 to 2008, 35.7% in

2009 to 2010, 34.9% in 2011 to 2012, and 37.7% in 2013 to 2014 (Ogden et al., 2015).

The age-adjusted prevalence of overweight and extreme obesity has also been reported for adults by the NHANES (Fryar et al., 2014). The prevalence of overweight adults was 34.0% in 1999 to 2000, 35.1% in 2001 to 2002, 34.1% in 2003 to 2004, 32.6% in 2005 to 2006, 34.3% in 2007 to 2008, 33.0% in 2009 to 2010, and 33.6% in 2011 to 2012. The prevalence of extreme obesity was 4.7% in 1999 to 2000, 5.1% in 2001 to 2002, 4.8% in 2003 to 2004, 5.9% in 2005 to 2006, 5.7% in 2007 to 2008, 6.3% in 2009 to 2010, and 6.4% in 2011 to 2012.

The number of adults who combine good dietary practice with regular physical activity in an attempt to attain an appropriate body weight has decreased. This decidedly negative trend may be related to the decline in physical activity in and outside schools. According to the YRBSS data from the CDC (2014), 29.4% of adolescents participated in daily school physical education in 2014 (down from 33.3% in 2009), and the target for *Healthy People 2020* is 36.6% (USDHHS, 2010). Additional changes from the YRBSS include a significant increase in the percentage of 9th to 12th graders who report playing video or computer games or used a computer for 3 hours or more per day (31.1% in 2011 compared with 41.3% in 2013) and a decrease in the percentage who played on at least one sports team (58.4% in 2011 compared with 54.0% in 2013).

In a seminal study that tracked physical activity over time using data from the Trois-Rivières Growth and Development Study, there was a significant but weak correlation between adult and childhood physical activity (Trudeau et al., 2004). Researchers from the same institution (Larouche et al., 2012) recently examined the effects of receiving different amounts of physical education during primary school (5 hours of weekly physical education vs. 40 minutes of weekly physical education) on the amount of physical activity during four life transitions (i.e., adolescence, postsecondary studies, entry into the labor market, and parenthood). They found a progressive nonlinear decline in the physical activity of both groups and differences between sexes during life transitions. The researchers suggest initiatives should

be undertaken to maintain or increase physical activity during these transition periods. In a similar type of study based on data from the National Longitudinal Study of Adolescent Health, increased physical activity during adolescence decreased the likelihood of young adults being overweight (Menschik et al., 2008). Using data from the Canadian Physical Activity Longitudinal Study, Brien and colleagues (2007) reported that previous cardiorespiratory fitness ($\dot{V}O_{2max}$) and previous BMI measurements are significant predictors of future weight gain and obesity in adults. Finally, a meta-analysis explored the different mechanisms through which physical activity during adolescence benefits adult health, such as reducing morbidity (Hallal et al., 2006).

If a standard is to be set for the importance of physical activity throughout the life span, it needs to start with children, who have the potential to develop lifelong healthy habits.

As the health care system moves toward a preventive model, primary care providers must facilitate a wellness attitude in their care recipients, which involves not only encouraging individuals to be physically active but also leading by example. Recommending regular exercise and espousing the benefits from personal experience can have a significant influence on individual involvement. Health care practitioners are in a position to inquire about and provide counseling for the exercise habits of their care recipients. For example, for each of the preferred physical therapist practice patterns (musculoskeletal, neuromuscular, cardiovascular/pulmonary, and integumentary), the first corresponding pattern is primary prevention/risk reduction. Although some progress has been made in providing preventive care to reduce risk, data indicate a shortfall in reaching the goal set for 2020 (USDHHS, 2010). Although there has been some improvement in some areas, overall the proportion of the population reporting physical activity has remained essentially unchanged, and progress is limited. Obviously, the progress that has been made toward the physical activity objectives for the year 2020 does not reflect a significant shift in the attitude of the general population or the health care profession. There are still populations at greater risk of obesity

based on race/ethnicity (National Institute of Diabetes and Digestive and Kidney Diseases, 2012; Whitson et al., 2011); school type, public versus private (Li & Hooker, 2010); and socioeconomic status (Balistreri & Hook, 2011; Scharoun-Lee et al., 2009) (Box 12-3).

Box 12-3

Populations With Low Rates of Physical Activity

- Women are generally less active than men at all ages.
- People with lower incomes and less education are typically not as physically active as those with higher incomes and education.
- Black Americans and Hispanics are generally less physically active than whites.
- Adults in northeastern and southern states tend to be less active than adults in north central and western states.
- People with disabilities are less physically active than people without disabilities.
- By age 75 years, one in three men and one in two women engage in no regular physical activity.

Aging

The biological changes attributed to aging closely resemble the effects of physical inactivity. The list for both aging and inactivity includes an increase in body fat and a decrease in all the following: aerobic capacity, muscle mass (sarcopenia), metabolic rate, strength and flexibility, bone mass, sexual function, mental performance, immune function, and sleep quality.

Among older adults, exercise can improve health, prevent disability

and hospitalizations, improve blood lipid profiles, and reduce body fat. According to the 2010 US census, the population aged 65 years or older has grown to 40.3 million people, an increase of 15% since 2000 (US Census Bureau, 2011). In 2012 there were an estimated 43.1 million older adults aged 65 years or older, and that number is expected to almost double to 83.7 million by 2050 (Ortman et al., 2014). Projected numbers and proportions of the US population of older adults have been reported: 43.1 million or 13.7% in 2012, 56.0 million or 16.8% in 2020, 72.8 million or 20.3% in 2030, 79.7 million or 21.0% in 2040, 83.7 million or 20.9% in 2050 (Ortman et al., 2014).

Exercise is especially important for older women, who constitute the majority of the older population, because it has the potential to improve bone health (Bielemann et al., 2013; Hamilton et al., 2010; Julián-Almárcegui et al., 2015) and reduce fracture risk as part of a multidimensional approach (Kemmler et al., 2013; Perry & Downey, 2012). The percentage of female older adults aged 65 years or older has been reported and projected as 56.4% in 2012, 55.1% in 2030, and 55.1% in 2050 (Ortman et al., 2014). The percentage drastically increases for reports and projections for older adults aged 85 or older: 66.6% in 2012, 62.4% in 2030, and 61.9% in 2050 (Ortman et al., 2014).

By exercising, older people can improve levels of cardiovascular, cardiopulmonary, and metabolic functions, including muscle performance and aerobic capacity. Several researchers have reported significant increases or improvements in strength (Candow et al., 2011), physical performance such as gait speed (Chou et al., 2012), flexibility (Marquard et al., 2012), self-efficacy (Park et al., 2011), quality of life (McGrath et al., 2010), balance (Rose & Hernandez, 2010), continence (Shamliyan et al., 2008), bone density (Alghadir et al., 2015), safety (fewer falls and fall-related injuries) (Caban-Martinez et al., 2015), and the ability to live independently (Cowan et al., 2009). Additional resources are available that discuss **exercise prescription** considerations and guidelines for the older adult (American College of Sports Medicine [ACSM], 2013; Chodzko-Zajko et al., 2009; Elsawy & Higgins, 2010; Liu et al., 2011a; McDermott & Mernitz, 2006; O'Donovan et al., 2010).

Older adults, in particular, need to be concerned about their nutritional status because the potential for malnutrition, a common problem for older adults, is associated with a decline in muscle strength and thus poorer outcomes, such as decreased function and performance (Bauer et al., 2008; Henwood et al., 2012; Jones et al., 2009; Mithal et al., 2013; Morgan, 2012; Tarnopolsky, 2008; Walrand et al., 2011).

The health of the musculoskeletal system depends on movement and activity. Bone is a dynamic tissue, constantly changing and adapting to the stresses to which it is subjected. Bone strength depends on stresses applied by muscular and weight-bearing activity (mechanical stress during active movement). Exercise may increase or maintain bone mineral density (BMD), but recent meta-analytic data suggest that the effects of exercises on BMD may depend on the mode of exercise, body part, combination of exercises (mixed loading), and other (e.g., pharmacological, tai chi) concurrent treatments (Almstedt et al., 2011; Alperson & Berger, 2011; Guadalupe-Grau et al., 2009; Howe et al., 2011; Martyn-St James & Carroll, 2009). To stay healthy, joints must do what they are designed to do—move and bear weight. The health of the cartilage covering the joint surfaces is vital for maintaining proper joint function. The only way the cartilage can receive nourishment is through the manufacture and distribution of synovial fluid, which delivers nutrients, removes waste products, and lubricates joint surfaces. Movement is vital for the creation of this environment of blood and lymph in and out of joint structures and the adjacent soft tissues. Without the stress of weight-bearing activity, normal bone and cartilage metabolism and repair become dysfunctional, resulting in injury and disease.

Effects of Exercise on the Aging Process

Everyone needs physical activity to be healthy. Human physiology has evolved in preparation for physical exertion. Until recently, survival through the vigor of daily living depended on a moderate degree of physical fitness. However, with mechanization and the style of living in today's society, daily life has become too sedentary. A

lifestyle of inactivity places the population at risk of death and morbidity, and the literature supports exercise as an essential element of health.

Regular physical activity can help maintain functional independence and improve the quality of life throughout the aging process (Figure 12-2). Physical and psychological benefits of increased physical activity have been documented widely in healthy and in chronically ill older adults (Arne et al., 2009; CDC, 2015; Dogra, 2011; Lin et al., 2010; Liu-Ambrose et al., 2010). Unfortunately, according to data from the BRFSS, less than 33.1% of older adults engage in physical activity (CDC, 2016a). According to the CDC (2015), older adults require at least 2.5 hours of moderate-intensity aerobic activity weekly, as well as muscle strengthening on 2 days or more per week. Considerable research has tested interventions to increase activity by younger adults and by populations of all ages. Interventions' research with older adults is being reported more frequently. The most common interventions are self-monitoring, general health education, goal setting, supervised center-based exercise, problem-solving, feedback reinforcement, and relapse prevention education. A few studies have examined multicomponent cognitive-behavioral group intervention (Zijlstra et al., 2009). Lifestyle activity in an older adult recommends the accumulation of minutes of physical activity spread over the entire day. Some evidence suggests the potential beneficial effects of lifestyle activity and the probability that some aging adults may be more receptive to lifestyle activity changes that include episodic exercise (Zijlstra et al., 2009).

FIGURE 12-2 Older adults can maintain functional independence while biking.

Cardiac Risk Factors

The literature strongly demonstrates that the risk of coronary heart disease (CHD) decreases as physical activity increases and that a plausible relationship between the decreased risk and a number of potential physiological and metabolic mechanisms exists (Ahmed et al., 2012; Ghadieh & Saab, 2015; Li et al., 2015; Pattyn et al., 2013):

- Increasing levels of high-density lipoprotein (HDL) cholesterol
- Decreasing levels of low-density lipoprotein (LDL) cholesterol
- Decreasing total cholesterol levels
- Decreasing serum triglyceride (TRG) levels
- Decreasing high blood pressure
- Improving glucose tolerance and insulin sensitivity
- Decreasing obesity; altering the distribution of body fat
- Reducing the sensitivity of the myocardium to the effects of catecholamines, thereby decreasing the risk of ventricular arrhythmias
- Enhancing fibrinolysis and altering platelet function

High-Density Lipoprotein and Serum Triglyceride Levels

Exercise has a major influence on lipoprotein metabolism, primarily affecting plasma levels of HDL and TRG. There is a strong negative correlation between CHD and plasma HDL levels. Increases in HDL level lower the total cholesterol to HDL ratio, thereby reducing CHD risk. Exercise, a common part of treatment of hypertriglyceridemia, may have a lowering effect on TRG levels (Cho et al., 2014; Lee & Heo, 2014; Vrablík & Češka, 2015). A meta-analysis of randomized controlled trials examined the effects of progressive resistance training on adults and found significant reductions in total cholesterol levels, the ratio of total cholesterol to HDL, and the levels of non-HDL, LDL,

and TRG (Kelley & Kelley, 2009). A similar systemic review examined exercise in obese children and found that aerobic exercise improved LDL and TRG concentrations and that combined exercise (aerobic fitness, strength, and flexibility training) improved the HDL concentration (Escalante et al., 2012). In another study of obese children, exercise significantly lowered total cholesterol, TRG, LDL, very low density lipoprotein, and insulin levels and significantly increased HDL levels when compared with no exercise (Zorba et al., 2011). A recent meta-analysis of randomized controlled trials compared the effects of diet, exercise, and both diet and exercise on total cholesterol, HDL, LDL, and TRG and found that exercise alone and when combined with diet results in positive changes in lipid and lipoprotein levels in adults (Kelley et al., 2012).

The effect of exercise on lipid metabolism may be related more to the volume (duration and frequency) than to the intensity of the exercise. In a systematic review, Tambalis and colleagues (2009) reviewed the literature for responses in the levels of blood lipids to a variety of modes and volumes of exercise. Moderate-intensity aerobic exercise training (less than 60% $\dot{V}O_{2max}$ or six metabolic equivalents) appears to have the greatest effect on HDL levels. However, stronger evidence suggested that high-intensity aerobic training promotes significant increases in HDL levels. This was observed among a wide range of 90 to 200 minutes per week. Resistance training supported a marked reduction in LDL levels, followed by a significant reduction in total cholesterol levels. The review found combining resistance and aerobic exercise can lead to remarkable reductions in LDL levels, significant increases in HDL levels, and significant decreases in total cholesterol levels (Tambalis et al., 2009).

Hypertension

According to the CDC, the age-adjusted percentage of the US population with hypertension increased from 25.5% in 1988 to 1994 to 30.0% in 2011 to 2012. The ACSM (2009a) and the American Heart Association (Braith & Stewart, 2006) recommend **resistance training** in the prevention and treatment of hypertension (Box 12-4).

Furthermore, the ACSM (Pescatello et al., 2004) summarizes evidence, of differing degrees, that supports the use of physical activity, dynamic aerobic training, dynamic exercise, and resistance training to decrease blood pressure in adults. The summary of the evidence supports regular endurance exercise to decrease blood pressure in older adults. There was no evidence to support a different blood pressure response to exercise between sexes and different ethnicities. A recent systematic review examined the effects of various forms of exercise training on resting blood pressure in healthy adults (Cornelissen & Smart, 2013). Only randomized controlled trials were included in the meta-analysis, and the results indicate that endurance, dynamic resistance, and isometric resistance training lower both systolic blood pressure and diastolic blood pressure. A similar meta-analysis reported the blood pressure–lowering effects of dynamic resistance training and isometric handgrip training (Cornelissen et al., 2011).

Box 12-4

Resistive Training Exercises

Chest Press (**Figures 1 and 2**)

- Lie on a bench with feet flat on the bench, or lie on the floor with knees bent and feet flat, whichever is more comfortable.
- Hold weights near shoulders with elbows out and palms facing away from the body.
- Exhale while extending arms straight up, following an “A” pattern with the weights touching at the peak.
- Slowly lower the weights back to original position while inhaling.
- Repeat 8 to 12 times.

Chest Fly (**Figures 3 and 4**)

- Lie on a bench with feet flat on the bench, or lie on the floor with knees bent and feet flat, whichever is more comfortable.
- With palms facing each other, extend arms above chest, keeping elbows slightly bent at all times.
- Inhale and lower arms perpendicularly away from the body until arms are out of peripheral vision.
- Exhale while returning to starting position by visualizing arms hugging a barrel that is lying on the chest.
- Repeat 8 to 12 times.

Bent Over Row (**Figures 5 and 6**)

- Bend at waist while supporting the body with one hand (on table, bench, etc.) and holding a weight with the other hand in an overhand grip.
- Keep knees bent while the weight is hanging perpendicular to the torso.
- Slowly pull the weight up to the chest as if starting a lawn mower, exhaling and keeping the elbow away from the body.
- Slowly lower weight back to starting position while inhaling.
- Repeat 8 to 12 times on each side.

Dumbbell Curl (**Figures 7 and 8**)

- Stand or sit with weights held at sides in an underhand grip, keeping elbows close to the body and upper arms stationary.
- Curl weights to the chin or upper chest while exhaling.
- Inhale while slowly lowering weights.
- Keep back straight throughout the duration of motion.
- Repeat 8 to 12 times.

Triceps Extension (**Figures 9 and 10**)

- While seated or standing in the neutral back position, lift the hand holding the weight straight above the head and in alignment with the ear.
- Keeping the upper arm tight, slowly bend the elbow to lower the weight between the shoulder blades.
- Use the free hand to support the elbow and to prevent movement in the upper arm.
- Raise the weight back to its original position by straightening the arm and exhaling.
- Repeat 8 to 12 times on each side.

The ACSM recommends endurance training should include aerobic activities with use of large muscle groups on most days of the week for 30 minutes or more (ACSM, 2009a). Low- to moderate-intensity aerobic exercise also appears to be effective in lowering blood pressure (Cornelissen et al., 2009; Hua et al., 2009; Roussel et al., 2009). The mechanisms underlying the exercise-training effect on lowering

blood pressure are not completely clear but may involve attenuation of sympathetic nervous system activity. This attenuation results in the dilation of peripheral blood vessels, which decreases systemic vascular resistance. Decreasing sympathetic nervous system activity may have a beneficial effect on the insulin resistance that is often observed in hypertensive people. The literature has also uncovered significant effects of both interval and continuous training of between 45 and 60 minutes on systolic and diastolic blood pressure (Lamina, 2010). Fagard (2011) reviewed the current literature and found inconclusive evidence for exercise intensity and its effect on blood pressure. This study observed two exercise groups, low-intensity exercise (33% of heart rate reserve) and high-intensity exercise (66% of heart rate reserve), performed three times a week for a 1 hour each time. The results revealed that systolic blood pressure decreases with both intensities but diastolic blood pressure decreases significantly after higher-intensity exercise (Fagard, 2011).

Hyperinsulinemia and Glucose Intolerance

Hyperinsulinemia and glucose intolerance account for the various types of diabetes. Diabetes mellitus encompasses a group of metabolic disorders that have in common an increase in blood glucose levels and associated metabolic dysfunction. Type 1 involves elevated blood glucose levels that are a result of a deficiency of circulating insulin caused by destruction of the pancreatic β cells, and type 2 diabetes involves elevated blood glucose levels from insulin resistance (decreased insulin sensitivity)—largely in skeletal muscles—or impaired insulin secretion (Nathan, 2015). Approximately 90% to 95% of those with diabetes have type 2 diabetes. According to the CDC, the age-adjusted percentage of the US population with diabetes increased from 8.8% in 1988 to 1994 to 11.9% in 2011 to 2012. In addition, adiposity and poor fitness are linked with insulin resistance (Larson-Meyer et al., 2010). Complications of diabetes include heart disease and stroke, peripheral arterial disease, retinopathy, nephropathy, peripheral neuropathy, and lower-extremity amputation (Deshpande et al., 2008).

Exercise, in addition to diet, is a first-line intervention for diabetes (Gulve, 2008). In a recent meta-analysis of randomized controlled trials, both diet and lifestyle interventions including exercise and physical activity decreased 2-hour plasma glucose and fasting plasma glucose levels in individuals with impaired glucose tolerance (Gong et al., 2015). In a similar meta-analysis of randomized controlled trials, researchers examined the effects of lifestyle interventions including exercise and physical activity on risk factors in individuals with type 2 diabetes and found a significant reduction in the level of hemoglobin A1c (HbA_{1c}), among other risk factors (Chen et al., 2015). A randomized control trial by Belli and colleagues (2011) examined the effects of 12-week overground walking training in individuals with type 2 diabetes. The exercise group performed walking at the ventilatory threshold velocity. When compared with the control group, the exercise group had significant reductions in HbA_{1c} levels (glycemic control) and body composition (body mass and BMI) and a significant increase in exercise capacity (peak oxygen uptake and exercise duration). Marcus and colleagues (2008) compared the effects of aerobic exercise with a combination of aerobic and high-force eccentric resistance exercise over the course of 16 weeks in individuals with type 2 diabetes. Both groups had a significant decrease in HbA_{1c} levels, decrease in amount of intramuscular fat, and increase in 6-minute walk distance, with no between-group differences. The aerobic and high-force eccentric resistance exercise group also had a significant gain in lean tissue and greater decrease in BMI when compared with the aerobic exercise group (Box 12-5: Diversity Awareness).

Box 12-5

Diversity Awareness

Walk Away From Ethnic Glucose Intolerance

The Pima Indians of the Gila River Indian Community in Arizona

have the highest documented incidence rates of type 2 diabetes in the world. On the island of Mauritius in the southwest Indian Ocean, all four ethnic groups (Hindu and Muslim Asian Indians, African Creoles, and Chinese) have unusually high rates of type 2 diabetes. In the United States, type 2 diabetes is 30% more prevalent in blacks than in whites. The presence of type 2 diabetes in each of these ethnic groups provides strong support for the existence of one or more modifiable risk factors in the cause of the disease.

Excessive weight gain is a strong independent predictor of type 2 diabetes. The development of type 2 diabetes (characterized by insulin resistance, hyperinsulinemia, and glucose intolerance) is related to weight gain in adults, particularly to fat accumulation around the waist, abdomen, and upper body (android or apple shape). This type of fat distribution is also associated with a higher risk of developing CHD. Adipose tissue is a major site for insulin insensitivity, and most obese individuals have increased insulin resistance or some degree of glucose intolerance, or both.

Physical activity has an important role in the prevention and treatment of type 2 diabetes. By helping to maintain a proper lean-to-fat body mass, either by losing weight or by preventing weight gain, physical activity may indirectly protect against the development of type 2 diabetes. The modulating effect of physical activity on fat stores helps to increase insulin sensitivity and glucose tolerance. Additionally, physical activity may directly affect glucose metabolism. The shorter-term effect of exercise can lower plasma glucose levels by enhancing the effect of insulin; long-term exercise improves insulin action and increases glucose tolerance.

Epidemiological studies of ethnic groups indicate that physical inactivity is also a risk factor for type 2 diabetes. In the United States, blacks and Native Americans have a disproportionate number of poor, unemployed, and disadvantaged individuals who lack access to the health care system. The least active individuals within these populations should be given the most attention because they have the most to gain. The methods and programs that are used to relay information to the public on the importance of physical activity need

to be varied, depending on the socioeconomic and cultural factors specific to ethnic populations. Promotion of physical activity by schools, communities, and government and health agencies, with these factors in mind, will significantly help achieve the goal of improving lifestyles and decreasing the incidence of type 2 diabetes.

In addition, several meta-analyses examined the effects of different modes of exercise on glycemic control. Strasser and colleagues (2010) examined the effect of resistance training with abnormal glucose metabolism and found significant improvements in glycemic control, with a mean HbA_{1c} level reduction of 0.48%. Irvine and Taylor (2009) found the following results in individuals with type 2 diabetes: progressive resistance exercise resulted in a significant reduction in HbA_{1c} level of 0.3% when compared with no exercise; there was no difference in HbA_{1c} levels between resistance and aerobic exercise groups; and progressive resistance exercise resulted in significant increases in strength when compared with aerobic exercise and no exercise. Chudyk and Patrella (2011) reported that aerobic exercise alone or combined with resistance training significantly reduced HbA_{1c} levels, systolic blood pressure, and triglyceride levels in individuals with type 2 diabetes. Furthermore, waist circumference was significantly reduced only when aerobic exercise and resistance training were combined.

During physical activity, contracting skeletal muscles work with insulin to enhance glucose uptake into the cells (Stanford & Goodyear, 2014; Turcotte & Fisher, 2008). Insulin resistance impedes glucose mobilization into cells, increasing plasma glucose levels and setting the potential for development of type 2 diabetes. Although insulin resistance in skeletal muscles may be the primary defect, the development of disease appears to be related to elevated insulin levels, a result of the body's response to the need to mobilize glucose into the cells. Additionally, this syndrome also often involves elevated TRG levels and hypertension, which contribute to the potential for disease. Exercise increases insulin sensitivity, improves the inherent effect of endogenous insulin, decreases obesity, and plays a role in

lowering TRG levels and blood pressure; therefore it is recommended in the management of type 2 diabetes (Chen et al., 2015; Gong et al., 2015; Gulve, 2008; Nathan, 2015; Polikandrioti & Dokoutsidou, 2009; Waryasz & McDermott, 2010; Weltman et al., 2009). With diet, weight control, and exercise, preventing or decreasing the need for oral antiglycolytic agents and insulin is possible while maintaining normal blood glucose levels. Physical activity may be most beneficial in preventing the progression of type 2 diabetes during the earlier stages of the disease process, before insulin therapy is required. Overall, physical activity has a significant positive effect on a chronic disease that is associated with a high risk of developing CHD.

Obesity

Overweight and **obesity** are conditions of excess body fat (adipose tissue). Adults are considered overweight if their BMI is 25.0 to 29.9 kg/m^2 and obese if their BMI is 30.0 kg/m^2 or higher. Furthermore, the ACSM (Wallace & Ray, 2009) considers those with a BMI of 40 kg/m^2 or higher as being extremely obese.

Obesity may also be defined as body weight that is equal to or greater than 120% to 125% of the ideal body weight. **Fat mass** (body fat percentage) is also important in determining the ideal body weight. The recommended body fat levels are approximately 15% to 16% for men and 23% to 24% for women (ACSM, 2009b). The average American man and woman tend to exceed the recommended body fat level. An increase in fat mass and the development of obesity occur when energy intake exceeds total daily energy expenditure for a prolonged period. Decreased physical activity may be both a cause and a consequence of weight gain over a lifetime.

The prevalence of obesity, as well as overweight and extreme obesity, is typically reported on the basis of BMI values, as is the case with the National Health and Nutrition Examination Survey (NHANES). Unfortunately, the prevalence of obesity in the United States remains high and has been increasing. According to the NHANES data for 2009 to 2012 (CDC, 2016b), from 2009 to 2012 35.3% of the US population was obese (up from 33.9% in 2005 to 2008). A nutrition and weight status objective (NWS-9) for *Healthy People 2020* is to reduce the proportion of adults who are obese to 30.5% in 2020. In the United States, no state has met the nation's *Healthy People 2010* goal to lower obesity prevalence to 15%. In fact, no state has an obesity prevalence less than 20%. The number of states with an obesity prevalence between 30% and less than 35% actually increased from none in 2000 to 19 in 2014, including Alabama, Delaware, Georgia, Indiana, Iowa, Kansas, Kentucky, Louisiana, Michigan, Missouri, Nebraska, North Dakota, Ohio, Oklahoma, Pennsylvania, South Carolina, Tennessee, Texas, and Wisconsin (CDC, 2014).

Furthermore, three states have a prevalence of obesity greater than 35%: Arkansas, Mississippi, and West Virginia.

According to the most recent NHANES data, the prevalence of obesity in women exceeds that of men in the non-Hispanic black, Hispanic, and Mexican American ethnic groups. Furthermore, the prevalence of obesity differs by racial/ethnic group for female adults only. That is, adult females of Mexican American (49.2%), Hispanic (44.4%), and non-Hispanic black (56.6%) racial/ethnic backgrounds have a greater prevalence of obesity than do those of non-Hispanic white (32.8%) background. In contrast, the prevalence of obesity is comparable for males of Mexican American (44.0%), Hispanic (40.1%), non-Hispanic black (37.1%), and non-Hispanic white (32.4%) racial/ethnic backgrounds.

Several studies have related increased fat mass and reduced physical activity to the risk of cardiovascular disease and overall mortality (Larson-Meyer et al., 2010). Both obesity and decreased activity are related to insulin resistance, elevated blood pressure, and elevated total and LDL cholesterol concentrations, all of which reduce with weight loss and fitness (Larson-Meyer, 2010). Nevertheless, obesity should be considered an independent target for intervention in health promotion. Being overweight and being obese are major contributors to many preventable causes of death. On average, higher body weights are associated with higher death rates (USDHHS, Prevention and Wellness, 2015).

Maintaining fitness and health is closely related to controlling weight. The literature supports the positive influence that physical activity has on body weight and obesity. A meta-analysis concluded that exercise resulted in weight loss in people who were overweight or obese (Shaw et al., 2006). In fact, in comparison with no treatment, the meta-analytic data show that exercise alone produced favorable changes in body weight, BMI, diastolic blood pressure, and serum triglyceride, serum HDL, and fasting serum glucose levels. A more recent meta-analysis examined the effect of exercise on body composition in menopausal women (Yeh et al., 2011). The results showed a significant decrease in weight, BMI, and body fat in

menopausal women who exercised. A recent study examined the ability of obese adolescents with diabetes to retain the benefits of a 12-week exercise intervention (Gow et al., 2016). Significant gains in aerobic fitness ($\dot{V}O_2$ peak) and time to anaerobic threshold were achieved after the intervention and were maintained for an additional 6 months.

Physical activity:

- Promotes a negative energy balance (burns calories)
- Increases metabolic rate for an extended period after the activity
- Increases metabolic efficiency for burning calories by increasing lean body mass
- Helps counteract the decrease in metabolic rate associated with low-calorie diets by preserving lean body mass
- Is a good alternative to eating when eating is a response to stress rather than to hunger

Unfortunately, most overweight people ignore exercise as a means of weight loss, or they exercise at rates below federal health guidelines (CDC, 2010).

Management of obesity involves a comprehensive program of nutrition management, behavior modification, and physical activity or exercise. The key to normalizing body fatness is long-term adherence and permanent lifestyle changes, not dieting or short-term exercise trials.

Increasingly sophisticated obesity treatments that demonstrate the best outcomes emphasize five components: behavioral techniques, cognitive strategies, social support, nutrition, and exercise. The effectiveness of physical activity is related to the frequency and duration of each activity session and the longevity of the activity program. Recommended ACSM guidelines for exercise include the following (Wallace & Ray, 2009):

- A program of low-impact aerobic exercise, increase in daily activities, and resistance training
- A frequency of 5 to 7 times a week

- A length of 40 to 60 minutes a day or 20 to 30 minutes twice daily

As long as calorie expenditure is similar, moderate lifestyle activity may be as effective as structured exercise. Moderate intensity appears to be most effective for total and fat calorie consumption during the activity.

Women tend to have a 5% to 10% lower resting metabolic rate than men and a higher percentage of body fat than men of similar weight. Consequently, women have a lower percentage of lean body mass and may not be as metabolically active as are men during exercise. Women may expend up to 40% fewer calories than do men during the same exercise protocol at the same relative intensity (Tremblay et al., 1985).

Fat in men is stored primarily in the upper body or upper abdominal region. Fat in women is primarily stored in the lower half of the abdomen, the hips, and the thighs. Adipose tissue metabolism tends to be different in various regions. The fat-metabolism response to exercise appears to be less in the femoral-gluteal region than in the upper body–abdominal region. Femoral-gluteal adipose tissue serves as an important source of energy during lactation. Women may not lose fat as easily as do men in response to exercise, because genetic differences are related to where and how fat is stored and metabolized. Consequently, women who need to lose weight may need to be more diligent about increasing the duration of their exercise training sessions and making resistance training a priority to facilitate maximal energy expenditure.

Several studies have examined parental awareness of weight status in children. A survey by the American Academy of Child and Adolescent Psychiatry (2004) of parents, 23% of whom had overweight children, reported that only 10.5% of parents with overweight children perceived their children's weight accurately compared with 59.4% of other parents. In a study by He and Evans (2007), 29.9% of the children examined were overweight or obese. However, on the basis of the parent's perception of their children's weight, only 18.3% were overweight or obese. Factors such as the child's sex, the child's ethnicity, and mother's weight contributed to the parent's inability to recognize weight status. In a study by Huang

and colleagues (2007), 61% of parents correctly identified their child's weight status, and these parents were also able to correctly identify the weight status of unrelated children in 58% of reviewed photographs. The results indicate that the parent's ability to correctly identify their child's weight status depends on their child's age and weight status. Moore and colleagues (2012) examined factors that influenced parental concern about their child's weight. Their results indicate that parents were significantly more likely to be concerned about their child's weight if the child was female, they believed the child to be overweight or obese, or the child was overweight or obese on the basis of the BMI.

Osteoporosis

Osteoporosis, or porous bone, is the most common bone disease and a major health threat. It is characterized by low bone mass and structural weakness of bone tissue, leading to bone fragility and increased risk of fractures (National Institutes of Health, Osteoporosis and Related Bone Diseases National Resource Center, 2011; Smith et al., 2009). In the United States an estimated 10 million people have osteoporosis and 44 million have low bone density and an increased risk of developing osteoporosis (National Osteoporosis Foundation, 2016). Furthermore, half of adults aged 50 years and older are at risk for breaking a bone, and one in two females and one in four males will fracture a bone due to osteoporosis. Unfortunately, the incidence of osteoporosis in women is greater than heart attack, stroke, and cancer combined (National Osteoporosis Foundation, 2016).

Some loss of bone occurs naturally after age 30 years. Twenty to thirty percent of bone mass development is regulated by environmental factors, such as nutrition and physical activity. In addition to the importance of optimizing physiological intake of calcium and vitamin D (Kalyani et al., 2010), and maintaining normal menstrual cycles for maximization of peak bone mass, physical activity plays a significant role in developing bone mass during childhood and adolescence and in maintaining skeletal mass into adulthood and old age (Bielemann et al., 2013). Two recent meta-analyses provide evidence to support the importance of the combined effects of nutrition and physical activity on bone health (Behringer et al., 2014; Julián-Almárcegui et al., 2015). Physical activities, those that involve weight-bearing in particular, increase BMD (Behringer et al., 2014; Borer, 2005) and provide support for a stronger skeletal foundation throughout aging. Additionally, systematic reviews examining the effects of different exercises in menopausal and postmenopausal women suggested that an active lifestyle and strength training may help to reduce fracture risk and preserve BMD, specifically spine and hip BMD, in osteopenic and osteoporotic

women (Howe et al., 2011; Hurley & Armstrong, 2012; Martyn-St James & Carroll, 2009; Zehnacker & Bemis-Dougherty, 2007). A systematic review supports the benefits of resistance training to improve the domains of physical function and activities of daily living in those with osteoporosis or osteopenia (Wilhelm et al., 2012). Inadequate calcium intake during growth has implications for peak bone mass, which may occur as early as the late teenage years or as late as the mid-30s, and may have implications for bone health later in life (Theobald, 2005). Unfortunately, Caucasian females in North America aged 4 to 8 years, 9 to 18 years, 19 to 50 years, and older than 51 years take in 105%, 64%, 74%, and 55% of the recommended amount of calcium respectively (Borer, 2005). Although dietary sources are the preferred means of achieving adequate calcium intake, foods fortified with calcium are becoming more prevalent and are manufactured to provide approximately 300 mg of calcium in each serving (see Chapter 11).

Bone mass increases during childhood and adolescence and peaks during the third decade of life. When a person reaches age approximately 30 years, age-related bone loss occurs throughout the skeletal system, in all races and in both sexes. However, there are significant differences in bone loss patterns between the sexes, with female sex being a risk factor for osteoporosis. Women have less bone mass than men at all ages, and by their mid-thirties can expect age-related bone loss of approximately 1% annually. The rate of bone loss accelerates rapidly during the first 5 years after menopause, with annual losses of 3% to 5% being common. By the fifth decade, or during their forties, women can anticipate a 10% loss of vertebral bone mass. Cumulative bone loss can approach 40% of peak bone mass over a woman's lifetime. Unfortunately, a loss of at least 30% of bone mass is required for detection on plain film radiographs (McKinnis, 2014). Therefore it is important to detect women at risk early in the natural course of the disease and to target interventions toward lifestyle-oriented health promotion. Additional risk factors for osteoporosis include Caucasian/Asian race, family history, low body weight for height, premature menopause, lack of physical activity,

long-term smoking, and excessive alcohol consumption (Mirza & Cannalis, 2015; Smith et al., 2009; Stagi et al., 2014). In addition, risk factors for osteoporotic fractures attributable to falls include sensory and coordination deficits, unsafe living situation, older age, musculoskeletal weakness, alterations in posture (e.g., increased spine kyphosis), diminished reflexes, medication use, and associated diseases (Hsu et al., 2014; Kessenich, 2007).

The ACSM recommends that osteoporotic people should engage in weight-bearing and impact exercises to promote strengthening and cardiovascular conditioning, as well as flexibility, coordination, and balance training to improve quality of life, maintain an active lifestyle, and decrease the risk of falls (Kohrt et al., 2004). Maintenance of bone mass may be related to the intensity of the physical activity and the degree to which the activity stresses the bone. Weight-bearing actions that stress the skeleton (walking, stair climbing, floor calisthenics, and aerobic dance) have a positive effect on bone density. Weight-bearing exercise, which increases mechanical stresses on the skeleton, is an important component of reducing osteoporosis risk. Such exercises should be performed for 20 to 30 minutes or more, at least three to five times per week (Smith et al., 2009). Recent intervention trials and meta-analyses suggest that low-impact to moderate-impact weight-bearing exercises combined with resistance and/or agility training facilitate the most effective gains in BMD, prevention of bone loss, and functional capacity in older men and women (Nikander et al., 2010). Aerobic exercise and resistance training have also been advocated for people with osteoporosis (Iwanto et al., 2010) and may give affected individuals more desire to participate in daily activities, promoting a more active lifestyle (Lirani-Galvao & Lazaretti-Castro, 2010). In younger women, the goal of exercise is to increase bone density; in older women who are already 30 to 40 years after menopause, a more realistic goal would be to decrease the risk of fractures through fall prevention. With respect to reducing fall risk in older postmenopausal women, Lirani-Galvao and Lazaretti-Castro (2010) found that tai chi may play a role in preventing osteoporotic fractures because of increases in muscle strength and improvements in balance and

decreased risk of falling; however, research has shown that tai chi does not support increases in BMD. Furthermore, it was found that the incidence of fragility fractures was noticeably lower in middle-aged to older men and women who participated in 3 to 4 days of moderate to vigorous physical activity per week (Nikander et al., 2010). A recent review also discusses the evidence to support the use of assistive devices such as spinal and foot orthoses for fall prevention (Hsu et al., 2014). See Box 12-6: Research for Evidence-Based Practice for a recent longitudinal study that supports the benefits of exercise to reduce the incidence of falls and fractures in older women with a history of falls (Kim et al., 2014).

Box 12-6

Research for Evidence-Based Practice

Falls and fractures in participants and excluded nonparticipants of a fall prevention exercise program for elderly women with a history of falls: 1-year follow-up study.

Objectives: To examine the effectiveness of strength and balance exercises to prevent falls in community-dwelling older adults with a history of falls.

Design: A 1-year follow-up study was conducted on 105 women older than 70 years who had experienced at least one fall in the previous year. Participants were randomly assigned to an exercise group or education group. A third group consisted of women excluded from participation. The exercise group performed strengthening and balance activities that increased in complexity in a sequential manner for 3 months. The education group received information on nutrition, cognitive function, and oral hygiene in the same period. Those excluded from the study were asked to continue their regular routines. Outcomes of interest, including falls, injuries, fractures, and function, were measured at three points in time: at the baseline, after intervention, and at 1-year follow-up. Falls, injuries, fractures, and function were measured at the baseline, after intervention, and

at 1-year follow-up.

Setting: Community health promotion center.

Participants: Community-dwelling women older than 70 years with a history of falls.

Intervention: Participants were randomly assigned to one of two groups: exercise (conducted twice per week for 3 months to improve strength and balance) (n = 52) and education (conducted once per month for 3 months; n = 53). Both groups were also compared with a group of excluded participants (n = 91).

Measurements: The primary outcome measures included fall rates, fracture rates, and odds ratios (ORs) for falls and fractures. Additional outcome measures included measures of balance, walking speed, and lower extremity strength.

Results: There was a significant difference (χ^2 = 7.069, P = 0.029) in fall incidences between groups: 19.6% in the exercise group, 40.4% in the education group, and 40.8% in the excluded group. There was also a significant difference (Fisher's exact test = 0.043) in fracture rate between groups: 10.0% in the exercise group, 9.5% in the education group, and 27.6% in the excluded group. When compared with the exercise group, those in the education group (OR 2.78) and the excluded group (OR 2.83) had significantly greater odds of falling, and those in the excluded group (OR 4.30) also had significantly greater odds of fractures. Additional significant differences between groups and over time included increases in one leg standing time, usual walking speed, knee extension strength, and dorsiflexion strength.

Conclusion: These findings support the use of strengthening and balance exercises to decrease the incidence of falls and fractures in those with a history of falls.

excluded nonparticipants of a fall prevention exercise program for elderly women with a history of falls: 1-year follow-up study. *Geriatrics & Gerontology International, 14*(2), 285–292.

Arthritis

Arthritis upsets the balance of joint health. Although rheumatoid arthritis and osteoarthritis have different causes and attack different parts of the joint, impaired joint function is the result. Cartilage is destroyed, and irregularities occur in the bone ends. As proper joint alignment changes, normal ROM is decreased, normal muscle balance and activity are altered, and disfigurement and dysfunction occur; and ultimately normal movement patterns are altered. Although there is an ongoing progression in arthritis that cannot be reversed by exercise, physical activity nevertheless helps to restore health to synovium and cartilage, increase strength and flexibility, decrease joint vulnerability, and delay the onset of dysfunction. Most importantly, exercise has been shown to reduce pain and joint stiffness, reduce fatigue, and improve function and psychological well-being in individuals with arthritis (Cooney et al., 2010; Kelley et al., 2015; Kujala, 2009; Nelson et al., 2014). Further evidence is needed to determine if postponing exercise is appropriate during exacerbations of rheumatoid arthritis (Cooney et al., 2010); however, vigorous exercise is typically contraindicated in individuals with acute joint inflammation (ACSM, 2009b).

Using exercise to counteract the effects of inactivity associated with arthritis is certainly a component to effective management (ACSM, 2009b). Although researchers have concluded that regular exercise cannot relieve or cure arthritis, exercise has the following quality-of-life benefits for people with arthritis (ACSM, 2009b; Cooney et al., 2010; Kujala, 2009; Nieman, 2000):

- Improvement in joint function and increase of ROM
- Increase in muscle strength and aerobic fitness that enhance daily activities of living
- Improvement in psychological state
- Decrease in loss of bone mass, and may promote increased BMD
- Decrease in the risk of chronic disease

Consequently, exercise programs based on individual needs and interests should emphasize exercises to increase joint ROM and flexibility (performed before aerobic or strength activities) and should also include muscle-strengthening (two to three times per week) and aerobic exercises (5–10 minutes with progression to a 30-minute session 3–5 days per week) and be functionally based (ACSM, 2009a).

The collective evidence strongly and consistently suggests that exercise is beneficial for individuals with osteoarthritis. The specific aspects of exercise prescription for individuals with osteoarthritis have been studied to differing extents. In terms of the different modes of exercise, various forms of exercise have been shown to be effective for osteoarthritis. A systematic review of studies of the effect of aquatic exercise on osteoarthritis concluded that aquatic exercise produces short-term beneficial effects on function and quality of life and, to a lesser extent, pain management (Bartels et al., 2007). A more recent systematic review examined the effects of aquatic exercise on symptoms and function associated with lower extremity osteoarthritis and reported significant effects for pain, self-reported function, physical functioning, stiffness, and quality of life (Waller et al., 2014). With respect to fall risk, the available evidence produces mixed results with use of aquatic exercise to reduce fall risk in individuals with hip and/or knee osteoarthritis, supporting the use of aquatic exercise in conjunction with fall risk education to effectively reduce fall risk, but not the use of aquatic exercise alone (Arnold & Faulkner, 2010; Hale et al., 2012). Lastly, an 18-week trial comparing aquatic exercise with land-based exercise found that although both modes of exercise improved function and pain management, the aquatic exercise group demonstrated a significantly greater reduction in pain level (Silva et al., 2008). Long-term effects have not been shown to date; thus, we suggest aquatic exercise either be incorporated into a broader exercise program or be modified and exercise increase regularly to promote adaptation to and avoid accommodation to the training stimulus.

With respect to non–aquatic-based exercise, an umbrella review found high-quality evidence supporting the beneficial effects of exercise on pain and function in individuals with osteoarthritis of the

knee (Jamtvedt et al., 2008). Similarly, a systematic review of the effects of strength training alone, exercise therapy alone, and a combination of exercise and manual therapy in individuals with osteoarthritis of the knee concluded that these modes of treatment improved function and reduced pain to a small degree, with the addition of manual therapy to treatment producing a moderate effect on pain (Jansen et al., 2011). A systematic review incorporating adults and older adults with knee osteoarthritis supported progressive resistance exercise and aerobic exercise as having a modest beneficial effect on strength, pain, and function (Keysor & Brembs, 2011). A recent systematic review of randomized controlled trials concluded that physical therapies including strength training, tai chi, and aerobic exercises improved balance outcomes and decreased fall risk in older individuals with knee osteoarthritis (Mat et al., 2015).

Available evidence may also support a small but positive benefit from education and self-management programs as complements to exercise to improve self-efficacy (May, 2010). Furthermore, additional evidence suggests that increased belief that physical activity can be beneficial to manage arthritis leads to higher levels of participation in physical activity (Ehrlich-Jones et al., 2011) and is significantly associated with decreased pain and fatigue, increased function, and a self-perceived positive effect (Bezalel et al., 2010; Hewlett et al., 2011; Pisters et al., 2010). Exercise intensity is another important consideration for exercise prescription in individuals with osteoarthritis (OA); however, unlike the mode of exercise, intensity has received little attention. There is limited research available that compares the outcomes in individuals with OA with the intensity of training; however, some evidence supports both high-intensity and low-intensity training as being of equal benefit in individuals with knee OA with respect to pain, strength, and function, without a difference in the rate of unfavorable effects. More research is needed to determine the optimal parameters for exercise in individuals with osteoarthritis, and an impairment-based, person-centered approach with consideration of comorbidities and accessibility is required (Bennell & Hinman, 2011).

Rheumatoid arthritis (RA) and **fibromyalgia syndrome** are two related arthritic conditions that have begun to be studied more. Evidence suggests that aerobic exercise in individuals with fibromyalgia can increase function and relieve some symptoms (Busch et al., 2008). However, evidence pertaining to the effectiveness of strength training to produce similar effects in individuals with fibromyalgia is of low quality (Kujala, 2009). A recent systematic review concluded that aquatic therapy can improve self-reported function capacity (Fibromyalgia Impact Questionnaire) and performance-based function (6-minute walk test) and reduce stiffness in individuals with fibromyalgia (Lima et al., 2013). In addition to evidence supporting the use of a combination of aerobic and strength exercises to improve outcomes in those with rheumatoid arthritis (Cooney et al., 2010), the use of tai chi as a form of activity in individuals with RA has also been considered. A case series study of the use of tai chi in individuals with RA supported significant reduction in swelling of joints and increase in strength and endurance as measured by the "timed sit to stand test," and suggests practicing tai chi may help individuals with RA increase their level of physical activity (Uhlig et al., 2010). Importantly, although the evidence has not shown that tai chi reduces pain or relieves other symptoms of RA, it does not appear to exacerbate these symptoms (Han et al., 2004). A meta-analysis of the effects of cardiorespiratory aerobic exercise in individuals with rheumatoid arthritis demonstrated small but meaningful effects on quality of life, function, and pain (Baillet et al., 2010). In addition, a recent systematic review examined the correlates in four categories (sociodemographic, physical, psychological, and social variables) with levels of physical activity in individuals with rheumatoid arthritis (Larkin & Kennedy, 2014). Positive correlations with physical activity were found for motivation, self-efficacy, health perception, and previous physical activity levels, whereas negative correlations were found for fatigue, a coerced regulation style (i.e., the extent to which the person believes the physical activity goal was set not by himself or herself but by others), and certain physiological variables.

Again, further evidence is needed to determine if postponing exercise is appropriate during exacerbations of RA (Cooney et al., 2010). A review of the studies of the effects of aerobic exercise, strength training, and aquatic therapy on individuals with fibromyalgia syndrome concluded there is evidence supporting benefits of exercise in this population to improve function and well-being, and decrease pain and stiffness (Busch et al., 2007; Kujala, 2009; Lima et al., 2013). Aerobic activities such as stepping and walking and strengthening exercises such as lifting weights or use of resistance exercise machines can be used in addition to stretching for flexibility. Although exercise is part of the overall management of fibromyalgia syndrome, the review by Busch and colleagues (2007) examined the effects of exercise when used separately or combined with other strategies such as education programs, biofeedback, and medications. In that review, aerobic exercises were done for at least 20 minutes once a day (or twice for 10 minutes), 2 days a week. Strength training was done two to three times a week and with at least 8 to 12 repetitions per exercise. The exercise programs lasted between 2.5 and 24 weeks. In a study by Sañudo and colleagues (2010), aerobic exercise was compared with combined exercise (aerobic, muscle strength, and flexibility exercises) and control (nonexercising) groups. Both exercise groups demonstrated significant improvements on the Fibromyalgia Impact Questionnaire and the Beck Depression Inventory. When compared with the aerobic exercise and control groups, the combined exercise group had significantly better outcomes on the SF-36 physical function, body pain, vitality, and mental health subscales and for ROM (shoulder and hip) measurements and grip strength. In a more recent study, Sañudo and colleagues (2012) examined the effect of whole-body vibration exercise on balance in women with fibromyalgia. The control group received an exercise training program, and the experimental group received the same exercise training program plus whole-body vibration exercises. The results indicated that the group with whole-body vibration demonstrated significantly better balance, as measured by the mediolateral stability index, when compared with the control group.

Low Back Pain

Low back pain is a common medical and social problem frequently associated with disability and absence from work. Low back pain is a multifactorial disorder that is unlikely to be caused by a single factor. Obesity is associated with an increased risk of low back pain, as well as an increased likelihood of seeking care for subacute and chronic low back pain (Shiri et al., 2010). The risk of low back pain increases as BMI increases: 2.9% when BMI is 20 to 25 kg/m^2, 5.2% when BMI is 26 to 30 kg/m^2, 7.7% when BMI is 31 to 35 kg/m^2, and 11.6% when BMI is 36 kg/m^2 or greater (Smuck et al., 2014). Contrary to commonly held opinion, there is a lack of evidence that a sedentary lifestyle is a risk factor for the onset of low back pain (Chen et al., 2009). However, higher levels of muscular and aerobic fitness are associated with a decreased risk of low back pain (Heneweer et al., 2012). A recent meta-analysis concluded that aerobic exercise can reduce pain and improve the physical and psychological functioning of individuals with chronic low back pain (Meng & Yeu, 2015). Roffey and colleagues (2010a) in a systematic review found strong evidence that there is no relationship between awkward occupational postures and low back pain. Specifically, it is unlikely that occupational bending and twisting (Wai et al., 2010a), occupational sitting (Roffey et al., 2010b), occupational standing or walking (Roffey et al., 2010c), occupational lifting (Wai et al., 2010b), occupational pushing or pulling (Roffey, et al., 2010d), occupational carrying (Wai et al., 2010c), and occupational manual handling and individual assistance (Roffey et al., 2010e) are independent risk factors for low back pain.

Exercise can, however, have a positive influence on low back pain. There is some evidence to support overground walking more than treadmill walking in the management of low back pain (Hendrick et al., 2010). A more recent study found a positive synergistic effect of a rehabilitation program consisting of 14 exercises and treadmill exercises on the low back extensor strength in individuals with chronic low back pain (Cho et al., 2015). A systematic review

concluded that exercise can effectively reduce pain and improve function in persons with chronic low back pain; however, there was no clear advantage for any one form of exercise (van Middelkoop et al., 2010). Staal and colleagues (2004) concluded that graded activity was more effective than usual care in reducing the number of days of absence from work because of low back pain. Olaya-Contreras and colleagues (2015) examined the effects of advising a group of people with acute severe low back pain to "stay active in spite of the pain," and they found no difference in pain intensity trajectory and a significantly higher level of physical activity when this group was compared with a group that was instructed to "adjust activity to the pain." Given the acknowledged detriments of bed rest, staying active is good advice for individuals with low back pain. A recently updated Cochrane Review found that exercise therapy for acute low back pain may be effective in reducing pain and improving function in persons with chronic low back pain and reducing absenteeism in persons with subacute low back pain (Hayden et al., 2005). Another Cochrane Review found moderate evidence that exercise following treatment for low back pain may reduce recurrent episodes of low back pain (Choi et al., 2010).

The spinal column is composed of 24 vertebrae stacked vertically, forming natural curves that allow the bony column to function with the resiliency of a spring. The intervertebral disks help with mobility and shock absorption. The health of the bony vertebrae and the cartilaginous disks depends on movement. The cartilage receives its nutrients from cyclical compression and decompression as a function of weight-bearing and non–weight-bearing movement. Similarly, repeated weight-bearing and non–weight-bearing activity stimulates vertebral bone integrity.

Muscles are intimately involved in the support and function of the spinal column. Maintaining the proper curves (anterior and posterior convexities) of lordosis in the cervical and lumbar vertebrae and kyphosis in the thoracic vertebrae is vital for sustaining the spring and shock-absorption qualities of the spine. The lumbar curve is especially influenced by three sets of muscles that are attached to the pelvis and

the lumbar vertebrae. By altering the tilt of the pelvis, these muscles can increase (iliopsoas muscle) or decrease (abdominal and hamstring muscles) the lumbar curve. In addition, the deep muscles of the back (paraspinal muscles) work in controlled synergistic and antagonistic fashions to control spinal planes of motion; they are also influential in supporting the spinal curves in posture. Weakness or shortening of any of these muscles can adversely impact posture and increase stress on the back. The result can be back pain from muscle strain, altered joint function (facet joints), and abnormal force on the intervertebral disks.

In a systematic review, Hayden and colleagues (2005) concluded that in persons with various levels of low back pain, exercise was beneficial in terms of reducing pain, improving function, and decreasing absenteeism. The American Pain Society and the American College of Physicians have also jointly stated that there is good evidence for the effectiveness of exercise in reducing chronic low back pain (Chou & Huffman, 2007). Specific types of exercise that have been shown to be effective in persons with low back pain include training of the deep and superficial paraspinal muscles as well as unweighted or suspended exercise. The only systematic review of the effects of unweighted movement on persons with chronic low back pain concluded that there was consistent and strong evidence to support unweighted exercise to decrease pain and improve function (Slade & Keating, 2007). Exercise targeting specific lumbar paraspinal muscles has been shown to substantially reduce pain and restore function (Chang et al., 2015; Hwangbo et al., 2015; Koumantakis et al., 2005; Shaughnessy & Caulfield, 2004). Although walking appears to be effective in the management of chronic musculoskeletal pain, including low back pain (O'Connor et al., 2015), Rasmussen-Barr and colleagues (2009) found that graded exercises target both deep and superficial muscles that support and control the lumbar spine and pelvis and were more effective in the long term in reducing disability and the need for recurrent treatment and improving pain self-efficacy.

The goal of exercise programs for individuals with low back pain is to prevent debilitation as a result of inactivity and to increase

endurance, strength, and flexibility, allowing a return to usual functional activities. Exercise recommendations and progression of activity are highly individualized on the basis of the origin, duration, and severity of pain. Strengthening exercises for trunk and extremity musculature have been demonstrated to benefit people with low back pain. Aerobic conditioning, such as walking, swimming, and stationary bicycling, is recommended to maintain endurance and prevent debilitation from inactivity (ACSM, 2013).

Advanced age, osteoporosis, arthritis, and low back pain are not reasons to exclude exercise from anyone's lifestyle. In fact, the opposite is true. These conditions are reasons to remain as physically active as possible to facilitate the ability to function throughout the aging process.

A referral to a physical therapist is warranted in most, if not all, cases of low back pain to allow there to be proper comprehensive management, which may include exercise as well as other safe and effective interventions.

Immune Function

The relationship between exercise and immune function has a fairly long history of study, and the interest that grew out of the human immunodeficiency virus (HIV) epidemic continues to stimulate investigations in this area. Several studies demonstrate that people with impaired immune function can exercise safely without risk to their health status and can enhance their physiological and psychological well-being with regular exercise (Fillipas et al., 2006; Galantino et al., 2005; Gomes-Neto et al., 2013; Sax, 2006; Terry et al., 2006). A systematic review concluded that progressive resistive exercise may increase body weight and limb girth and aerobic exercise may improve adipose levels and lipid profiles by decreasing fat in tissues and blood in individuals with HIV (Fillipas et al., 2010). Another systematic review concluded that resistance exercise may improve body composition by decreasing body fat and increasing muscle strength, aerobic exercise may also improve body composition and increase aerobic capacity, and concurrent training may improve all outcomes evaluated in individuals with HIV (Gomes-Neto et al., 2013).

Furthermore, two recently updated meta-analyses suggest that aerobic exercise, either alone or in conjunction with progressive resistance exercise, can be safely performed by adults with HIV/acquired immunodeficiency syndrome (AIDS) and may increase fitness and improve body composition and well-being (O'Brien et al., 2009, 2010). Recommended parameters include exercising at least three times per week for 20 minutes over a period of 5 weeks or more (O'Brien et al., 2010).

The effect of exercise on immune system markers (e.g., CD4 levels, CD4/CD8 ratio, or viral load) in people with HIV/AIDS is unclear. Reviews discuss the effects of exercise on immune function in individuals with HIV/AIDS and report conflicting findings (Anderson, 2006; Dudgeon et al., 2004). A meta-analysis compared aerobic exercise groups with nonexercising groups and found no

significant differences in CD4 count, CD4 percentage, or viral load (Nixon et al., 2005). Similarly, meta-analytic data compared the combination of aerobic and progressive resistance exercise with no exercise and found no significant differences in CD4 count (O'Brien et al., 2004). Despite the fact that the CD4 count did not differ between exercising and nonexercising groups, there were significant beneficial changes in depressive symptoms, mean body weight, mean arm and thigh girth, and maximum heart rate for those in the exercising groups (Nixon et al., 2005; O'Brien et al., 2004). In another study, Jaggers and colleagues (2015) examined the effects of combined aerobic and resistance training on the psychological well-being of adults with HIV and found significant decreases in depression and mood states (Profile of Mood States) for the exercise group. The control group, the members of which were allowed to engage in sedentary activities, showed a significant increase in the perception of stress (Perceived Stress Scale). Evidence suggests that regular exercisers and athletes are less likely to become ill than sedentary women (Nieman, 1994) and middle-aged men and women (Matthews et al., 2002). In direct contrast, evidence also suggests that athletes are also at increased risk of infection during increased periods of training or after competition (Nieman, 1994; Nieman et al., 1990; Pedersen & Bruunsgaard, 1995; Peters-Futre, 1997). Another reported finding is that after exercise, sedentary individuals have a higher risk of infection than active individuals (Kiwata et al., 2014). A recent review concluded that immune function, both innate and acquired, of athletes under heavy training is often observed to decrease by approximately 15% to 25%, but studies on whether this change increases infection risk remain inconclusive (Walsh et al., 2015).

Classic epidemiological studies indicate that a J-curve relationship may exist between the intensity of exercise and the risk of upper respiratory tract infection (URTI) (Nieman, 1994; Pedersen et al., 1998). That is, in theory, moderate exercise may decrease the risk of URTI below that of a sedentary individual, but high-intensity exercise may raise the risk above average. In direct contrast, Lee and colleagues (1992) concluded that immune function was not linked to

the risk of URTI in a group of cadets during basic training, and Pyne and colleagues (1995) reported similar rates of URTI between elite swimmers under intense training and age- and gender-matched sedentary controls. Similarly, Gleeson and colleagues (2013) reported that high-exercising (≥ 11 h/wk) and medium-exercising (7–10 h/wk) groups had more URTI episodes than the low-exercising (3–6 h/wk) group. Factors that confound studies on the relationship between exercise and URTI include failure to distinguish between new infection and the clinical manifestations of a dormant infection (Gleeson et al., 2002) and failure to distinguish between airway hyperresponsiveness and URTI (Langdeau & Boulet, 2001).

Immune system changes that are apparently related to the intensity of exercise have been identified. Moderate-endurance exercise stimulates the neuroendocrine system, which causes changes in the function and numbers of various immune system cells, such as the natural killer, CD4, and CD8 cells. Evidence also indicates that moderate exercise is associated with a prolonged improvement in the killing capacity of neutrophils (one of the most efficient phagocytes). Several immune marker changes suggest increased risk of illness in those who engage in high-intensity exercise, including a low level of salivary immunoglobulin (antibodies), low serum complement levels, low lymphocyte count, depressed natural killer cell activity, low helper and suppressor T cell ratio, and decreased neutrophil phagocytic capacity (Mackinnon, 1992; Nieman, 1994; Pedersen & Ullum, 1994). Most aspects of immunity in male and female athletes are not significantly different (Gleeson et al., 2011).

Changes in immune cell counts and activity may be related to hormonal immunoregulation. Moderate exercise increases the release of immunostimulatory hormones, such as growth hormone and endogenous opiates (β-endorphin and methionine enkephalin). The increase in the levels of β-endorphins with exercise seems to have a positive effect on natural killer cell activity. Conversely, intense exercise is associated with increases in the levels of catecholamine and corticosteroid (cortisol), which have immunosuppressive characteristics (Mackinnon, 1992). High-intensity exercise is also

associated with muscle cell damage and inflammation. The immune system is involved in tissue repair. It is theorized that while immune cells are busy with the repair process, host protection may suffer. A window of opportunity for infection during recovery from high-intensity exercise appears to exist. Accordingly, rest is recommended after vigorous exercise to allow the body to recover, and moderate exercise may be the better choice for enhancement of health and well-being.

There is convincing evidence that exercise and physical activity have a significant protective effect on the gastrointestinal system, and, in particular, against colon cancer (Martin, 2011). However, there is less convincing evidence for the following conditions: gastric and pancreatic cancers, gastroesophageal reflux disease, peptic ulcer disease, nonalcoholic fatty liver disease, cholelithiasis, diverticular disease, irritable bowel syndrome, and constipation (Martin, 2011).

Evidence also suggests that physical activity is a modifiable risk factor for breast cancer (Bardi, 2007). Physical activity appears to lower the risk of developing many conditions, in particular breast cancer (Warburton et al., 2007). Unfortunately, physical activity during adolescence does not appear to play a protective role for the risk of breast cancer later in life (Gammon et al., 1998). A recent meta-analysis concluded that physical activity may reduce all-cause breast cancer–related deaths and breast cancer events in breast cancer survivors (Lahart et al., 2015). Another meta-analysis concluded that physical activity may decrease the risk of prostate cancer, and encouraged men to engage in regular physical activity (Liu et al., 2011b). A synthesis of clinical practice guidelines, systematic reviews, meta-analyses, and individual studies suggests that exercise may minimize or prevent adverse physiological effects of cancer and its treatment (Ingram & Visovsky, 2007). A recent position statement on immune function and exercise (Walsh et al., 2011) offered the following conclusion: “There is consensus that exercise training protects against some types of cancers. Training also enhances aspects of antitumor immunity and reduces inflammatory mediators. However, the data linking immunological and inflammatory

mechanisms, physical activity, and cancer risk reduction remains tentative."

Preliminary findings in the area of immunosenescence, the natural decline in immune function that occurs with aging, suggest that regular exercise and increased fitness may have potential immune restorative properties and improve the "immune risk profile" in elderly people (Simpson & Guy, 2010).

Mental Health

People who exercise regularly generally state that they feel better, have increased self-esteem, and have a more positive outlook on life. Not only do they feel better physically, they also they feel better mentally. Epidemiological research with both men and women suggests that physical activity may be associated with improvements in positive affect and general sense of well-being (USDHHS, 2015). Much of the work has focused on depression (Cooney et al., 2013; Josefsson et al., 2014), anxiety (Bartley et al., 2013; Wegner et al., 2014), stress (Georgiades et al., 2000; Rimmele et al., 2007), and schizophrenia (Firth et al., 2015; Gorczynski & Faulkner, 2010).

Evidence from a review of the literature (prospective studies, randomized controlled trials, and meta-analyses) found that exercise protects against and is an intervention for mild to major depression (Graven et al., 2011; Nahas & Sheikh, 2011). A recent meta-analysis concluded that exercise can reduce depressive symptoms in individuals with arthritis and other rheumatic conditions (Kelley et al., 2015). Research by the National College Health Assessment examined the association between vigorous/moderate or strength-training exercises and mental health in a national sample of college women (Adams et al., 2007). Both vigorous/moderate and strength-training exercises were positively associated with perceived health. Furthermore, both vigorous/moderate and strength-training exercises were negatively associated with several indicators of mental health (e.g., depression, anxiety, and suicidal ideation). Similarly, research examined the association between exercise and mental health and concluded that mental health is modifiable through exercise (Galper et al., 2006; Windle et al., 2010).

The mental health benefits of physical activity, as an intervention, have been summarized elsewhere and include promoting mental health and well-being in healthy adults, preventing and treating mental disorders, and supporting psychosocial rehabilitation (Nyström et al., 2015; C. W. Wang et al., 2014; F. Wang et al., 2014).

Investigations have focused on populations across the life span, including children, young adults, and older adults. Based on a limited number of small trials, a recently updated Cochrane Review concluded that, when compared with no intervention, exercise reduces anxiety and depression in children and young adults (Larun et al., 2009). Another Cochrane Review suggests that long-term exercise, of various types, is most likely to have a beneficial effect on mood in adults; however, the magnitude of the effect is indeterminate at this point (Mead et al., 2009). Researchers examining major depressive disorder recommended an exercise prescription that is supervised, individually customized, at least 30 minutes, and at least three times per week (Nyström et al., 2015). Yoga has also been shown to be effective in treating depression (Cramer et al., 2013).

In a recent systematic review of the effect of exercise on cognitive function in older adults, Tseng and colleagues (2011) suggested that there were positive benefits to adopting unimodal, simple exercises for cognitively impaired older adults and a more diversified, multimodal program for healthy older adults. They also recommended an exercise regimen of 6 weeks in duration, at least three sessions per week lasting 60 minutes each, to increase the likelihood of a positive effect on cognition.

Furthermore, the effect of exercise on individuals with various disorders or diseases, such as schizophrenia, cancer, or other chronic illnesses, has been studied. In a systematic review, Herring and colleagues (2010) concluded that although exercise in sedentary persons with a chronic illness reduces anxiety, training programs lasting as few as 12 weeks and consisting of sessions of at least 30 minutes resulted in the largest reductions in anxiety. A Cochrane Review of the psychological and physical effects of dance and movement therapy on persons with cancer was unable to arrive at a conclusion because of a dearth of high-quality studies in this area, although there may be a positive effect on quality of life in persons with breast cancer (Bradt et al., 2011). Based on a limited number of small trials, an updated Cochrane Review concluded that regular exercise may improve both physical and mental health and well-being

in persons with schizophrenia (Gorczynski & Faulkner, 2010). Exercise had been shown in two meta-analyses to improve health-related quality of life in those scheduled to receive, actively undergoing, or having completed cancer treatment (Mishra et al., 2014, 2015).

Various types and modalities of exercise have been used in studies; an example of one such intervention is tai chi. Tai chi significantly improved both psychological (perceived well-being) and physical (functional capacity, knee extension strength, and flexibility) health over baseline levels (Macfarlane et al., 2005). In a systematic review and meta-analysis of the effect of tai chi on psychological well-being, Wang and colleagues (2010) demonstrated an apparent association with reductions in anxiety, depression, mood disturbance, and stress, as well as improvements in self-esteem. A more recent review examining various populations again supported the benefits of tai chi for treatment of depression, treatment of anxiety, general stress management, and exercise self-efficacy (F. Wang et al., 2014). Yoga has also been shown to decrease depression and anxiety in a variety of conditions (Cramer et al., 2013; Pascoe & Bauer, 2015). Similarly, qigong exercise has been shown to reduce stress and anxiety in healthy adults when compared with waiting list controls (C. W. Wang et al., 2014).

Exercise Prescription

The literature certainly reflects both the physiological and the psychological benefits that can be experienced with commitment to an active lifestyle. In short, regular physical activity or exercise can help people feel better, look better, and perform better. Unfortunately, as discussed, Americans have failed to embrace the concept and health value of an active lifestyle. Many have been overwhelmed by the misperception that to gain health benefits they must perform vigorous, continual exercise. The result has been discouragement in getting started and poor compliance in staying with it. "No pain, no gain" has been an unfortunate and common refrain (Box 12-7: Quality and Safety Scenario).

Box 12-7

Quality and Safety Scenario

Less Pain, More Gain

In an attempt to encourage increased participation in physical activity, a panel of scientists from the CDC and the ACSM came together to review the evidence related to physical activity and to issue a public health message concerning the recommended types and amounts of physical activity. The evidence clearly indicates that the protective effects of exercise can be achieved at more moderate levels of intensity than had been recommended previously. The health and fitness benefits of exercise appear to be related more to the total amount of exercise performed (calories expended) rather than to the specific exercise intensity, frequency, and duration. The recommendations are as follows:

- Adults should perform 30 minutes or more of moderate-intensity (brisk) physical activity on most (or all) days of the week, for a weekly total of 3 to 4 hours.

- The activity need not be continuous; benefits can be realized with short bouts of activity (a minimum of 10 minutes) over the course of the day.

- This amount of activity will expend approximately 150 to 200 calories per day (the equivalent of walking 2 miles briskly) or 1000 to 1400 calories per week.

- All types of activity can be applied to the daily total (raking leaves, dancing, or gardening).

- Lower-intensity activities should be performed more often, or for longer periods, or both. More vigorous activities should be performed for shorter periods or less frequently.

Because most adults do not meet these standards, they have the most to gain by incorporating a few minutes of increased activity into their day, gradually building up to 30 minutes a day. People who are active on an irregular basis should strive to be more consistent. People who prefer more formal exercise can choose to participate in more vigorous, organized exercise regimens, sports, and recreational activities.

Sedentary individuals gain the most by increasing their activity to the recommended level. However, any person who already meets the standards can derive some additional benefit by becoming more active.

People who do a little bit of exercise are better off than those…who do none and those who do a little more are better off still (Franklin, 1993).

Franklin, B. (1993). How much exercise is enough? In *Encyclopedia britannica* (pp. 471–476). Los Angeles: Encyclopedia Britannica, Inc.

People need to be reminded that many of their daily physical activities are actually forms of exercise (Figure 12-3). This approach to physical activity serves as a good foundation to a healthy lifestyle. However, when possible, individuals should also be encouraged to include more formal exercise training in their overall activities to

promote optimal cardiorespiratory fitness and significantly increase muscle strength and endurance. The amount of exercise required to achieve these goals is determined by the parameters of an exercise prescription:

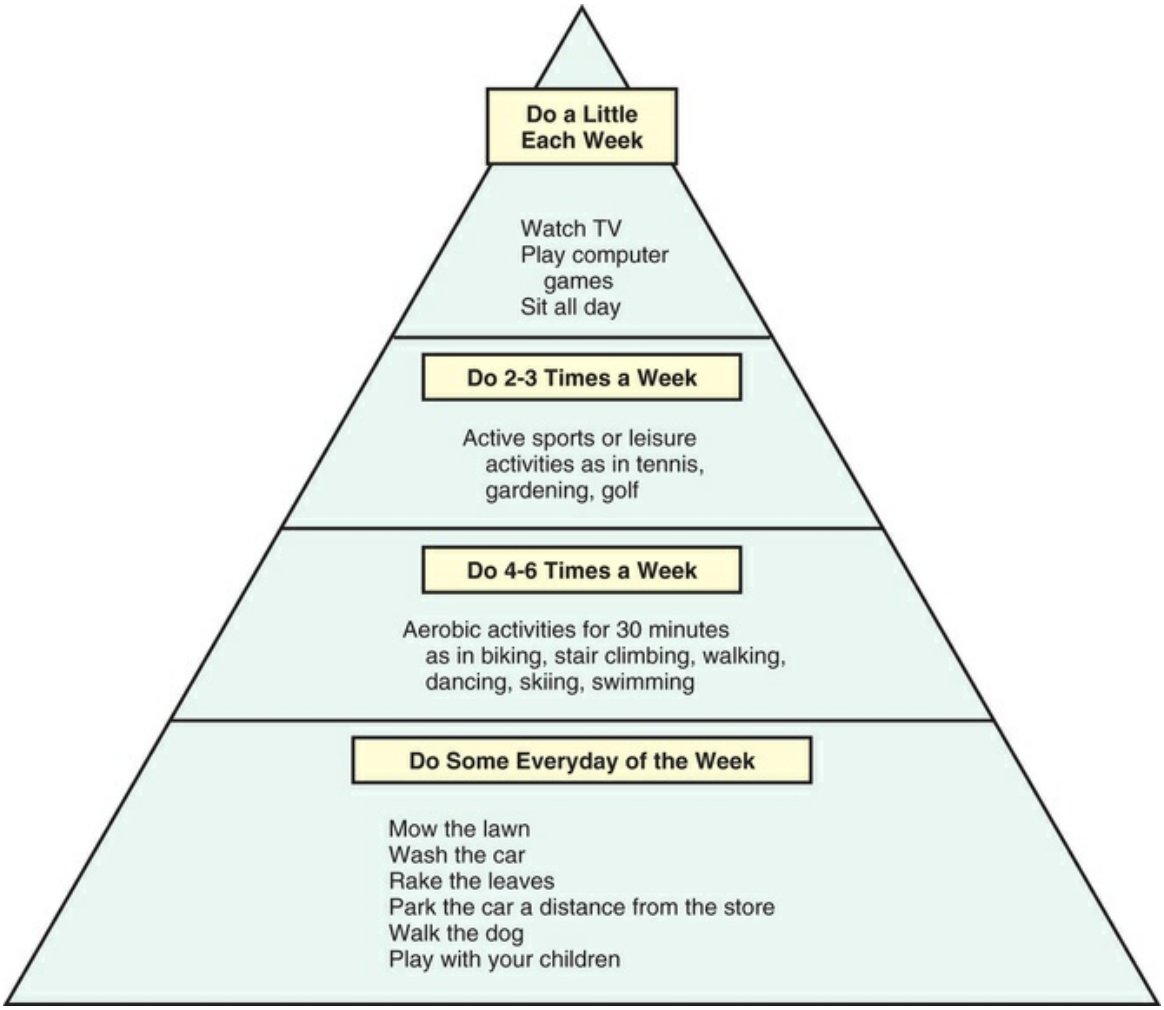

FIGURE 12-3 Physical activity pyramid.

F (frequency)	Aerobic exercise three to five times a week Resistance training two to three times a week
I (intensity)	Moderate to vigorous, by heart rate and perceived exertion
	Able to complete each resistance exercise, 8 to 12 repetitions, without strain
T (time)	20 to 60 minutes, plus warm-up and cool-down periods
	15 to 30 minutes to complete a series of 8 to 10 resistance exercises
T (type)	Aerobic (walking, jogging, biking, swimming, rowing, cross-country skiing, elliptical trainer, NordicTrack, StairMaster, aerobics, dancing, skating, or rollerblading)

	Resistance training (weight machines, free weights, and calisthenics such as push-ups, sit-ups, or pull-ups) (ACSM, 2013)

Aerobic Exercise

The benefits of aerobic exercise are cumulative; therefore a frequency of three to five times a week is recommended. Every other day is a good frame of reference and allows recovery between training sessions, potentially decreasing the chance of overuse injuries. The benefits of exercising more than five times a week are outweighed by the risk of injury, especially with higher-impact activities. When more frequent exercising is a goal, cross-training is recommended. **Cross-training** means performing different types of exercise on different days of the week or performing different types of exercise within one session. The benefits of cross-training include a decreased risk of musculoskeletal injury, an increased potential for total body conditioning, and improved long-term compliance because variety decreases boredom and eliminates the exercise barrier of limited choices.

The intensity of exercise that results in health and fitness benefits ranges from moderate to vigorous and is comfortable, but challenging (brisk). Intensity is defined by the objective measure of heart rate (HR) and the subjective measure of perceived exertion. The increase in HR during exercise has a strong linear relationship with exercise intensity and aerobic capacity. Resting heart rate is the HR measured at rest. Maximum heart rate is the rate measured at the highest workload tolerated during exercise. Maximum heart rate also decreases with age; a generic formula for determining maximum heart rate is 220 minus age. Formulas for determining appropriate exercise HRs have been developed that take resting heart rate and maximum heart rate into consideration.

The **Borg scale** for rating perceived exertion is a psychophysical category scale for the subjective rating of sensations associated with the intensity of physical work (Borg, 1973, 1982) (Figure 12-4). The scale uses ratings based on the individual's overall feeling of exertion

and physical fatigue. These ratings correspond well with metabolic responses to exercise, such as HR and oxygen consumption. The strong linear relationship between HR and the rating of perceived exertion (RPE) was originally suggested by Borg and has been verified by subsequent studies. Correlation coefficients from 80% to 90% have been reported consistently with use of a variety of work tasks and exercise conditions (Borg, 1973, 1982; Skinner et al., 1973). A meta-analysis has shown the Borg scale to be a valid measure of exercise intensity with a strong link between RPE and HR (Chen et al., 2002). In addition, recent studies support use of the Borg scale for various populations, including individuals with stroke (Sage et al., 2013), obesity (Coquart et al., 2012), and fibromyalgia (Soriano-Maldonado et al., 2015), and have quantified its ability to predict $\dot{V}O_{2max}$ (or $\dot{V}O_2$ peak) (Coquart et al., 2014). However, perceptions of exertion and the relationship with HR are influenced by both physiological and psychological factors (aches, cramps, pain, fatigue, shortness of breath, anxiety, depression, and introversion or extroversion). Smutok and colleagues (1980) noted that some individuals are more accurate in regulating exercise intensity by RPE than are others and that this variability may be more the result of psychological than physiological factors. Other factors that may alter the strong relationship between HR and RPE are drug-related situations (β-blockers), age, and disease states (Hautala et al., 2013; Mampuya, 2012).

FIGURE 12-4 Water skiing is a form of intense exercise.
(From Cummings, N. H., Stanley-Green, S., & Higgs, P. [2009]. Perspectives in athletic training. St. Louis: Mosby.)

Despite this potential for variability in perception, RPE correlates well with HR clinically, and together they form a complementary means of helping individuals determine a comfortable, beneficial level of exercise intensity. An RPE of 11 to 14 corresponds well with 50% to 85% of maximum heart rate. Subjective parameters include being slightly short of breath, but not out of breath; being able to talk without difficulty, but unable to sing a song easily; being pleasantly fatigued, but not exhausted; and having mild musculoskeletal discomfort, but no pain.

Attention to RPE helps a person develop a sense of body awareness and an appreciation for the body's response to the stress of activity. Awareness of RPE helps people listen to their bodies and become aware of how it feels to move, where they carry tension, and where they have discomfort. With this increased awareness, individuals can choose how they want to respond, adjusting their exercise practice on a daily basis, making the activity more enjoyable, decreasing the risk of injury, and improving long-term exercise compliance.

The recommended duration of aerobic conditioning exercise is generally 20 to 60 minutes. Less than 20 minutes usually provides minimal benefit. However, for people who are unaccustomed to

exercising or for those who are greatly deconditioned, short durations are permissible, gradually increasing to a beneficial, comfortable level as tolerance and confidence increase. Everyone has to start somewhere, and doing a little is much better than doing nothing at all.

The benefit of sessions longer than 45 to 60 minutes is again outweighed by the potential for injury. Exercising for more than 60 minutes on occasion is certainly not wrong, but a person who increases the duration should consider decreasing the intensity. Increases in cardiorespiratory fitness can also be accrued from intermittent bouts of moderate to vigorous exercise (10-minute segments) on a workout day. As discussed, longer bouts of exercise are more beneficial for weight loss. The range of acceptable duration allows greater flexibility, giving reassurance of benefit to the individual who varies exercise choices daily on the basis of capability, interests, and life demands.

As mentioned, many different choices for the mode of aerobic exercise are available. A question that is often asked is "What is the best type of aerobic exercise?" The answer is "The one that the individual is willing to do on a regular basis." Different aerobic exercises have different benefits; they all have their advantages and disadvantages. From a cardiovascular point of view, with relative intensity, frequency, and duration being equal, the benefit is about the same for all modes. Probably the best scenario is cross-training, which results in the greatest number of optimal all-around benefits. However, the most important recommendation is that the person starts moving—choosing the person's favorite exercise will increase the likelihood of adhering to an exercise program.

Walking is probably the most accessible and popular form of aerobic exercise. Done briskly, walking provides a good cardiorespiratory challenge in 60% to 80% of the adult population. Walking is also an activity that nearly everyone can do, requires little equipment or cost, can be done almost anywhere, and can be a social or a solitary activity, depending on individual needs. Walking is often the recommended exercise of choice for people who are greatly deconditioned or for those who have physical limitations. Considered

a low-impact activity, walking can be easily regulated to accommodate a wide range of fitness levels and motor abilities. Cycling, rowing, and swimming (or water walking or other water aerobics) are non–weight-bearing to low–weight-bearing activities that may be good choices for individuals with physical limitations. Aquatic exercise is a good alternative for individuals with musculoskeletal limitations who need some weight relief with exercise, such as individuals with advanced osteoarthritis. Although the buoyancy of the water provides this weight relief, the water also provides resistance to the limbs as they move, encouraging an increase in intensity and conditioning. Individuals should be encouraged to do the types of aerobic exercise that best fit their needs, interests, and lifestyles while providing reasonable benefits.

Warm-Up and Cool-Down Periods

In addition to the endurance phase of exercise, warm-up and cool-down periods should be a regular part of the exercise session. The **warm-up period** usually lasts 5 to 10 minutes and may include light stretching, calisthenics, or performance of the chosen aerobic activity at a low intensity. This approach prepares both the musculoskeletal system and the cardiorespiratory system for the transition from rest to exercise by increasing blood flow, respiration, body temperature, and muscle flexibility. The warm-up period decreases the risks of injury and heart irregularities.

The **cool-down period** follows the endurance phase and usually lasts 5 to 10 minutes. This phase allows the body to readjust gradually from the demands of exercise back to the baseline. Stretching and slow, rhythmical movement help to increase muscle elasticity, prevent blood pooling and hypotension, and facilitate dissipation of body heat and removal of lactic acid. The result is the prevention of injury, light-headedness, fatigue, and muscle soreness.

Yoga is an excellent example of one form of exercise to use during warm-up and cool-down periods. The word yoga means union or "established in being," which implies a mind-body connection. Simply defined, yoga is mindful stretching. The mind is quiet, and

awareness is focused on feeling the body as it moves. Movement into and out of yoga postures (called asanas) provides the necessary stimulation of weight-bearing activity to help keep bones strong, provides the movement to increase joint ROM, and stretches and tones muscles. The sun salute (*surya namaskar*), a series of 12 flexion-extension yoga postures linked together as one fluid movement by the breath rhythm, is a wonderful practice to include in the warm-up and cool-down phases of exercise, providing both physiological and mind-body benefits.

Yoga also helps develop an appreciation for the experience of the basic resting state, a mindfulness of how it feels to be relaxed physically and mentally during the activity. In this form, exercise becomes an inner experience: that is, quiet and settled on the inside, dynamic and lively on the outside. The yoga philosophy encourages an appreciation of body sensations, slow stretching, and maintenance of proper posture, all of which help to prevent injury and promote health. There is a growing body of evidence to support the use of yoga to increase ROM, reduce pain, improve posture, function, mental health, and sleep patterns, reduce disability, and improve quality of life in select populations (Alfonso et al., 2012; Bussing et al., 2012; Ebnezar et al., 2012; Holtzman & Beggs, 2013; Visceglia & Lewis, 2011).

Flexibility

Flexibility is a basic component of physical fitness. Warm-up and cool-down periods provide the opportunity to work on stretching muscles and increasing joint ROM. A safe stretch is one that is gentle and relaxing; a little discomfort may be felt as the muscle stretches, but the discomfort should never reach the point of pain. Stretching mindfully, as in yoga, will ensure a safe stretch. Holding the position for 10 to 20 seconds and repeating the stretch three to five times will encourage optimal flexibility (ACSM, 2013).

Resistance Training

Studies suggest that people who maintain or increase their flexibility and strength are better able to perform daily activities and avoid injury and disability (Pate et al., 1995). Resistance training increases muscle strength and endurance, increases muscle mass, increases metabolic efficiency, maintains or increases bone density, prevents limitations in performance of everyday tasks, decreases the effort required to perform these tasks, and decreases the potential for injury during physical activity.

On average, after their early 20s people lose approximately half a pound of muscle every year through lack of use. This reduction in muscle mass is largely responsible for a decrease in resting metabolic rate, which may translate into weight gain. Resistance training is recommended for the general population because it has a positive effect on many of the degenerative problems associated with the aging process.

Every individual should try to perform activities throughout the day that stimulate muscle strength and endurance. Activities that involve lifting, carrying, or performing repetitive movement against a resistance (vacuuming, raking, shoveling, or baking bread) help preserve lean body mass. If these types of activities are not performed on a regular basis, then the guidelines for resistance training provided in Box 12-4 are suggested. These guidelines are not meant to represent workouts performed by bodybuilders and competitive weight lifters; they are not meant to result in significant muscular hypertrophy. The purpose of weight training from a health perspective is to develop healthy muscles that provide the strength to do daily activities without risk of injury and to stimulate bone health.

The figures in Box 12-4 demonstrate several suggested resistance exercises for upper body strengthening. Resistance training for all major muscle groups is appropriate, but individuals often choose to concentrate on the upper body because these muscles tend to be neglected in daily activity and other exercise regimens. The ACSM (2013) recommends the incorporation of bilateral and unilateral, and single-joint and multijoint exercises, including total body exercises. Although many people believe that they need to do three sets of each

exercise, excellent results can be attained by doing one set (Hass et al., 2000). A recent meta-analysis of the effect of single versus multiple sets on muscle hypertrophy showed multiple sets yielded a 40% greater increase in muscle hypertrophy (Krieger, 2010). The ACSM recommends three to five sets of 8 to 12 repetitions (ACSM, 2013). The weight that is lifted should result in near muscle fatigue at the end of each set (this differs substantially depending on the muscle being trained, the amount of resistance, and the fitness level of the athlete) and should be performed without strain and while maintaining proper form. Once 12 to 15 repetitions can be completed without fatigue, the resistance can be increased (by 5% or less), or the same weight can be used to do an additional set to fatigue. The movements should be performed slowly, preferably coordinated with the breath. Rest intervals differ substantially in the literature; however, a review suggested that 3 to 5 minutes allows hypertrophy and power development and 1 to 3 minutes allows endurance gains (de Salles et al., 2009). The ACSM suggests 1 to 3 minutes of rest between sets to develop endurance and 3 to 5 minutes to develop strength and power. Slow, controlled movements result in greater benefits, lower risk of injury, and more appreciation of how the body feels as its muscles are challenged. The recommended frequency depends on the individual and should be two to three times per week for novice levels, three to four times per week for intermediate levels, and four to five times per week for advanced levels (ACSM, 2013). The exercise variables that constitute the exercise prescription must always be chosen to meet the specific needs and limitations of each individual.

Exercise the Spirit: Relaxation Response

Exercise should not be considered merely a physical regimen with objective outcomes (calories burned and repetitions completed). Exercise is also a process of challenging the body and the mind to gain a sense of well-being and a feeling of accomplishment, an opportunity to learn about who we really are.

Most people understand the physical benefits of exercise, and some people enjoy the challenge of being physically active, but few realize the learning potential inherent in physical activity. Success in embracing a physically active lifestyle may involve a change in focus from the mechanics of exercise to an appreciation for how it feels and what it means to move. Physical activity can be time spent in meditation that fuels both the body and the spirit.

The **relaxation response** (RR) is an inborn set of physiological changes that offset those of the fight-or-flight (stress) response. When elicited, the RR results in a "letting go" of physical, emotional, and mental tension. It is a physiological response inborn in everyone and, although it can sometimes occur without the individual being aware of it, people generally need to develop techniques that help them let go on a more regular basis. Some techniques that are used commonly to elicit the RR include diaphragmatic breathing, meditation, imagery, mindfulness, yoga stretching, and repetitive exercise.

The RR can be combined with exercise to facilitate the release of tension and improve self-awareness and the feeling of well-being. However, a shift in attitude about exercise is also involved, with the focus becoming the process and awareness of movement. Successful elicitation of the RR involves two basic components: a repetitive focus (the breath, a mantra, and the cadence or rhythm of physical activity) and a nonjudgmental attitude (about everyday thoughts and the quality of performance) (Benson & Stuart, 1992). Berger and Owen (1988) have developed exercise characteristics that facilitate stress

reduction and support an exercise environment that allows the successful elicitation of the RR. Activities must:

- Be pleasant and enjoyable.
- Be noncompetitive (competition implies judgment about the self and others).
- Be predictable (elicitation of the RR involves a shift in awareness from the external to the internal environment that will happen only with a sense of safety and reliability).
- Be repetitive and rhythmical (the cadence of activity provides a focus for awareness).
- Facilitate abdominal breathing (watching the breath serves to anchor thoughts in the moment; in combination with cadence, it provides a focused awareness).
- Continue for 20 to 30 minutes at a comfortable intensity on most days of the week (continuity restores a sense of serenity).

All forms of exercise can be used to gain this experience. As discussed, yoga involves mindful stretching with a breathing focus, providing an environment for successful elicitation of the RR. **Tai chi** is another exercise practice with roots in Eastern philosophy. Known as moving meditation, tai chi combines movement with focused awareness, involving a physical and cognitive focus for moving in choreographed forms that become a meditation.

The quality of body awareness can also be brought into a more traditional exercise practice. Aerobic exercise lends itself well to the elicitation of the RR, because it has rhythmical and repetitive form and because it facilitates abdominal breathing. The practitioner can focus on the breath rhythm, the step cadence of walking or jogging, the pedaling cadence of bicycling, or the stroke cadence of swimming. Mantras can be used to create a positive mindset and to focus the mind in the present moment as the experience unfolds. Resistance training takes on new meaning when coordinated with the breath. Focusing on the muscles and how it feels to move through the ROM enhances the knowledge of what feels good and what does not, providing feedback on accepting physical challenge.

Exercise focus can and should vary on a daily basis depending on need, mood, and intent. Some days it feels right to focus on the more physical aspects of the activity, appreciating the challenge of working harder or longer. Other exercise sessions may be more contemplative, letting creativity run, working through the tension of a lingering stressor, quieting the mind for relaxation, listening to music, or appreciating nature. Focusing on the process rather than the outcomes brings meaning and purpose to the activity and helps achieve something more valuable than mere physical outcomes.

When exercise integrates mind and body, it stops being something that has to be done and instead becomes something desired. Being mindful during physical activity and exercising in the moment increase awareness. With awareness comes choices in the possibilities of self-care. Exercise for fitness of the spirit, walk for the soul, and just let the body do the work. There is a growing body of evidence to support the use of tai chi to improve balance in confidence, decrease pain, improve cognitive function, mental health, and functional mobility, decrease disability, increase self-efficacy and quality of life, and reduce fall risk in select populations (Hall et al., 2011; Huang et al., 2011; Leung et al., 2011; Rand et al., 2011; Wayne et al., 2014).

Monitoring the Inner and the Outer Environment

The primary purpose of exercise is to enhance health. However, because exercise involves stress to the body, the potential to cause or exacerbate health problems is inherent. When a person is not feeling well, the exercise effort should be decreased or stopped until the individual is feeling better. With an infection, a cold, or influenza, the body is under stress, and overexertion will only increase that stress and possibly lengthen the healing time. The level of activity should be adjusted to accommodate how the individual feels, slowly progressing to normal workout levels until strength and energy return. This philosophy also holds true for chronic diseases such as arthritis and HIV infection. During an acute exacerbation, activity should be limited to necessary activities of daily living, but on a regular basis staying active is important, adjusting activity levels as tolerated. Exercise can be a useful tool in coping with chronic illness.

Missing an occasional workout will not affect the fitness level; choosing to stop or reduce the amount of exercise when not feeling well is the right choice. However, after missing workouts for 2 weeks, a decline in fitness is inevitable. When one starts again, resumption of the activity should be slow, gradually working back to the usual level of activity. Inactivity for 3 to 5 months results in the loss of all conditioning benefits gained, and resumption of exercise involves starting over (ACSM, 2013). Being aware of the external exercise environment is also important. Extremes of heat and cold affect performance as the body adjusts to different temperatures and wind conditions. Changing the time of day for exercise (early morning and later evening are better choices for humid days), adjusting fluid intake, and varying the length of warm-up and cool-down periods will increase tolerance for environmental conditions and enhance exercise safety.

Fluid News

Proper hydration before, during, and after exercise is an important component of a good fitness program. Extra fluid is needed to support physiological homeostasis during exercise, especially during hot weather. The following hydration recommendations are from the ACSM (2011). Before exercising, recommendations include drinking 16 to 20 ounces of water or sports beverage at least 4 hours before exercise and then drinking 8 to 12 ounces of water 10 to 15 minutes before exercise. According to the ACSM, a sports beverage should generally contain 4% to 8% carbohydrate, 20 to 30 meq of sodium per liter, and 2 to 5 meq of potassium per liter. During exercise, hydration recommendations include drinking 3 to 8 ounces of water every 15 to 20 minutes when exercising for less than 1 hour or drinking 3 to 8 ounces of a sports beverage every 15 to 20 minutes when exercising for more than 1 hour. The ACSM also recommends not drinking more than 1 quart per hour during exercise. After exercise, the ACSM recommends drinking 20 to 24 ounces of water or sports beverage for every 1 pound lost. As noted earlier, under certain circumstances the ACSM recommends consuming beverages containing electrolytes and carbohydrates during exercise over water alone. For exercise routines lasting longer than 1 hour, a sports beverage with carbohydrates and electrolytes enhances performance and is recommended (Sawka et al., 2007). This type of liquid provides muscles with energy and helps delay fatigue while meeting fluid needs. Sports beverages containing a 4% to 8% carbohydrate concentration are designed to replace carbohydrates at the proper rate during exercise. They also contain sodium, which promotes fluid retention, enhances flavor, and protects against hyponatremia, which can occur with lengthy exercise sessions. Most sports drinks provide 14 to 20 g of carbohydrate per 8-ounce serving. The recommended intake is 5 to 12 ounces every 15 to 20 minutes. Which sports drink is the best? Several brands should be tried to determine personal preference in taste, but one should be chosen that contains approximately 50 to 80 calories per 8-ounce serving; any more and the carbohydrate concentration will inhibit fluid absorption. Table 12-1 provides choices for sports drinks that

both hydrate and energize individuals.

TABLE 12-1

Sports Drinks That Hydrate and Energize Individuals

Brand	Calories	Carbohydrate (g)
All Sport (20-oz size)	150	40
Cytomax	95–100	20
Endura	120	29
Gatorade	104	27
Hydra Fuel	100	17
Isostar	148	35
MET-Rx ORS	148	38
Perform	100	25
Powerade	109	27
Power Surge	200	48
Race Day	100	28
Vitamin Water	100	26
SoBe	80	20
Propel	20	6

All values are for 16 oz unless noted otherwise.

Special Considerations

Most adults do not need to consult a physician before starting a moderate-intensity physical activity program. However, men older than 40 years and women older than 50 years who plan a vigorous program (intensity more than 60% of maximum heart rate or $\dot{V}O_{2max}$) or who have either chronic disease or risk factors for chronic disease should consult an appropriate health care provider before starting exercise (Table 12-2 and Box 12-8).

TABLE 12-2

American College of Sports Medicine Recommendation for Medical Examination and Exercise Testing Before Beginning an Exercise Program

	APPARENTLY HEALTHY		INCREASED RISK		
	Younger[a]	Older	No Symptoms	Symptoms	Known Disease[b]
Moderate exercise[c]	No	No	No	Yes	Yes
Vigorous exercise[d]	No	Yes	Yes	Yes	Yes

[a]Younger implies age 40 years or younger for men, and 50 years or younger for women.

[b]Individuals with known cardiac, pulmonary, or metabolic disease.

[c]Moderate exercise is defined by an intensity of 40% to 60% of $V \cdot O_{2max}$, or if the intensity is uncertain, an effort well within the individual's current capacity and that can be comfortably sustained for a prolonged period (60 minutes), slow progression, and generally noncompetitive.

[d]Vigorous exercise is defined by an intensity of more than 60% of $V \cdot O_{2max}$, or if the intensity is uncertain, exercise intense enough to represent a substantial cardiorespiratory challenge or result in fatigue within 20 minutes.

From American College of Sports Medicine. (2014). *Guidelines for exercise testing and prescription* (9th ed.). Philadelphia: Lippincott Williams & Wilkins.

Box 12-8

Symptoms and Signs Suggestive of Cardiopulmonary Disease

- Pain, discomfort (or other anginal equivalent) in the chest, neck, jaw, arm, or other areas that may be ischemic in nature
- Shortness of breath at rest or with mild exertion
- Dizziness or syncope
- Orthopnea or paroxysmal nocturnal dyspnea
- Ankle edema
- Palpitations or tachycardia
- Intermittent claudication
- Known heart murmur
- Unusual fatigue or shortness of breath with usual activities

These symptoms must be interpreted in the clinical context in which they appear because they are not all specific to cardiopulmonary or metabolic disease.

People with CHD or diabetes have special exercise needs. Earlier in this chapter the ways in which exercise and physical activity positively affect primary and secondary prevention in both disease processes were discussed. Limitations in the ability to exercise are related to the severity of the disease and the signs and symptoms of intolerance. For people with CHD and diabetes mellitus, safety with starting a new exercise program requires supervision and guidance from knowledgeable health care providers. Before starting the program, these individuals should have a medical evaluation, including an exercise tolerance test, to determine functional capacity

and the severity of disease.

Coronary Heart Disease

Exercise plays a strong role in rehabilitation after a cardiac event such as myocardial infarction (MI), coronary artery bypass surgery, percutaneous transluminal coronary angioplasty or stent placement, and angina. Increased physical activity appears to benefit individuals from all these groups. The benefits include the following (Cornelissen et al., 2011; Heran et al., 2011; Lavie & Milani, 2011; Menezes et al., 2012; Milani et al., 2011; Oerkild et al., 2011):

- Reduction in blood pressure (systolic and diastolic)
- Reduction in total and cardiovascular mortality
- Reduction in hospital admissions
- Reduction of symptoms
- Reduction in obesity
- Increase in exercise tolerance and functional capacity
- Increase in the confidence and ability to carry out usual activities of daily living
- Improvement in psychological well-being and quality of life

Despite the numerous benefits noted previously, cardiac rehabilitation and exercise training is underused by older adults (Menezes et al., 2012).

Generally, people with CHD demonstrate a reduction in $\dot{V}O_{2max}$ and the ability to do submaximal levels of work. With exercise training, the increase in $\dot{V}O_{2max}$ in persons with CHD averages approximately 20% after 3 months. This improvement in conditioning is the result of both central (cardiac) and peripheral (muscular) changes (ACSM, 2009b). Some of the most significant increases in exercise tolerance have been noted in individuals with angina. With a decrease in submaximal HR or a decrease in systolic blood pressure resulting from conditioning, myocardial oxygen demand is decreased and individuals are able to do a greater amount of work before reaching the anginal threshold. This boost is reflected in an observed increase

in the heart rate–pressure product (RPP: HR × SBP) at the anginal threshold (ACSM/AHA, 2007). An increase in functional capacity allows progression of exercise tolerance and progression with daily activities and leisure or vocational activities.

Appropriately prescribed and conducted exercise training programs increase exercise tolerance and physical fitness in individuals with CHD. Moderate and vigorous regimens are of value, but care must be taken to determine safe exercise parameters for each individual. The parameters of the exercise prescriptions are the same as those for the general population, including frequency, intensity, duration, and mode of exercise.

Aerobic exercise increases cardiorespiratory fitness and functional capacity. Any of the aforementioned aerobic exercises are acceptable for this population, depending on the level of fitness and musculoskeletal limitations. Traditionally, resistance training was not commonly recommended for individuals with CHD. The belief was that lifting weights resulted in a disproportionate rise in blood pressure, increased the myocardial oxygen demand, and increased the risk of angina and MI. However, data from several studies indicate that moderate, supervised weight training is feasible, tolerable, and beneficial for individuals with hypertension and CHD. Strength training can keep the heart healthy by helping to control body weight, reduce cholesterol levels, and regulate blood glucose levels. Guidelines for determination of appropriate individual training include an aerobic capacity of at least four to five metabolic equivalents, an ejection fraction of greater than 30%, and the absence of severe, symptomatic aortic stenosis. However, clinical experience demonstrates that people with severer disease can use small hand weights to increase muscle tone without risk of cardiovascular compromise.

The exercise intensity for persons who have had a cardiac event but who have not had a symptom-limited exercise tolerance test should be kept at a low level based on an elevated heart rate of 20 to 30 beats per minute above the resting heart rate and an RPE of less than 12. After an exercise tolerance test has been performed, intensity should then be

prescribed on the basis of 50% to 85% of maximum heart rate and an RPE of 11 to 14, or below the ischemic, anginal, or arrhythmic threshold. The duration and frequency recommendations are similar to those for the general population. People who are the most deconditioned may need to exercise at lower intensities, for short durations, and more frequently throughout the day. Generally, a reasonable goal is three to five times per week for 20 to 40 minutes, plus 5 to 10 minutes for each warm-up and cool-down period (ACSM/AHA, 2007).

Diabetes

Exercise has long been regarded as part of the triad in the management of diabetes in conjunction with diet and medication (insulin or oral medication). In the early 1900s it was determined that exercise lowers the blood glucose concentration of people with diabetes. After the introduction of insulin, studies revealed that exercise can potentiate the hypoglycemic effect of injected insulin. More recently, findings suggest that in individuals who have poor control (i.e., excessive blood glucose levels), exercise may induce a further increase in blood glucose levels, resulting in ketosis. On average, people with diabetes have a lower maximum heart rate, achieve a lower cardiac output at maximal exercise, and have a higher blood pressure during exercise, resulting in lower maximal oxygen consumption. However, these individuals can increase their exercise capacity with training and can experience the benefits related to overall fitness and cardiorespiratory training similar to the benefits gained by people without diabetes.

Apparently, both benefits and risks from exercise exist for people with diabetes. The overall goals regarding physical activity should be to teach individuals to incorporate activity into their daily life, pursue an exercise program if they wish, and develop strategies to avoid the complications of exercise.

As discussed, in addition to diet and weight loss, regular physical activity is an important modality in the prevention and treatment of type 2 diabetes. Regular physical activity can prevent or delay type 2

diabetes, with up to a 58% risk reduction in high-risk individuals when combined with modest weight loss, as well as positively affecting lipid levels, blood pressure, cardiovascular events, mortality, and quality of life (Colberg et al., 2010). Furthermore, a recent meta-analysis found that lifestyle modifications, such as diet, exercise, and education significantly reduced risk factors (i.e., lower cholesterol, high blood pressure, and diabetes) associated with the development of CHD in individuals with type 2 diabetes (Chen et al., 2015).

People with type 2 diabetes should monitor their blood glucose levels and determine their responses to exercise. However, individuals with type 2 diabetes can usually follow the same exercise prescription parameters as those of the general population. Although the same exercise benefits can be achieved by people with type 1 diabetes, the inherent behavior and function of endogenous insulin makes exercising a more difficult proposition for these individuals. The major functions of insulin are to promote glucose uptake into the cells and to control metabolic homeostasis during exercise, working in synergy with the counterregulatory hormones. With exercise, insulin secretion decreases slightly and the concentrations of counterregulatory hormones increase. This increase stimulates hepatic glucose production, which balances the increased use of glucose by the working muscles, maintaining normoglycemia. However, with injected insulin the plasma insulin concentration does not decrease with exercise, hepatic glucose is not produced as quickly as it is used, and a decrease in blood glucose concentration results. In contrast, people who have poorly controlled diabetes with decreased plasma insulin concentrations already have elevated blood glucose levels because there is insufficient insulin to assist glucose transport into cells. During exercise the liver is stimulated to produce more glucose, which causes a further elevation in blood glucose levels, worsening the hyperglycemic condition. Ketosis may also result from increased mobilization and incomplete combustion of free fatty acids in muscle cells and accelerated ketone body formation in the liver (Federici & Benedetti, 2006).

Although each person with diabetes should be evaluated and given

individual exercise recommendations, the goals of an exercise program are universal:

- Maintain or increase cardiovascular fitness to prevent or minimize long-term cardiovascular complications.
- Increase flexibility that is impaired as muscle collagen becomes glycosylated.
- Increase muscle strength, which may deteriorate as a result of neuropathy.
- Allow people with type 1 diabetes to safely participate in and enjoy physical activities or sports.
- Assist with weight control for people with type 2 diabetes.
- Allow people with diabetes to experience and gain the same benefits and enjoyment from regular exercise as do people without diabetes.

Box 12-9: Innovative Practice presents a list of recommendations and precautions for people with diabetes who are interested in regular physical activity and exercise. Table 12-3 presents recommended food adjustments when exercising. Table 12-4 presents the peak effects of different medications for diabetes. Box 12-10: Genomics presents findings from a meta-analysis that examines the association between genetics and the odds/risk of type 2 diabetes.

Box 12-9

Innovative Practice

Recommendations and Precautions for People With Diabetes Who Are Interested in Regular Physical Activity and Exercise

- Notify primary care physician, ophthalmologist, and podiatrist of intent to exercise.
- Monitor blood glucose level before and 20 to 30 minutes after exercise to determine the response to exercise.

- Be sure blood glucose level is less than 300 mg/dL in those with type 1 diabetes or less than 400 mg/dL in those with type 2 diabetes, and urine test results are negative for ketones (if blood glucose level is greater than 240 mg/dL). If blood glucose level is consistently equal to or greater than 250 mg/dL, improved control must be established before continuing exercise.

- If possible, exercise approximately 1 hour after meals, when blood glucose level is highest. This plan helps with weight loss, because extra food will not have to be eaten to ward off hypoglycemia. When exercising before meals, a snack may be necessary. (See Table 12-3 for suggestions on food adjustments to maintain blood glucose balance with exercise.)

- Know the action and peak times of insulin dosage and avoid exercising at the peak. (Table 12-4 shows the peak action of insulin preparations.)

- Consider adjusting oral medication or insulin dosage to prevent low blood glucose level during exercise. The adjustment will depend on the intensity of the exercise, the duration of the exercise session, and the type of insulin that is used during exercise.

- Be alert to the hypoglycemic lag effect that may occur 12 to 24 hours after vigorous exercise; an extra snack after exercise will help.

- Avoid injecting insulin into a muscle area that will be active during exercise; the pumping action of the muscle may accelerate absorption of the insulin and cause a rapid decrease of blood glucose level.

- Use proper footwear and frequently inspect the feet.

- Avoid high-impact activity when prone to neuropathy in the legs or feet or when there is a history of neuropathy.

- Keep systolic blood pressure below 180 to 200 mmHg in the

presence of eye or kidney disease.

- Exercising every day is best, but should be done at least three to four times per week. Start with 10 to 20 minutes and gradually increase to 30 to 40 minutes at 50% to 75% of maximum heart rate. Continuous aerobic activity helps maintain good blood glucose level control better than intermittent activities. Do not forget the 5-minute to 10-minute warm-up and cool-down periods.
- Avoid high-intensity anaerobic exercise, but low- to moderate-intensity resistance training is acceptable.
- Carry a concentrated form of carbohydrate (sugar packets, glucose tablets, or hard candy) when exercising.
- Wear some form of diabetes identification.
- People with type 2 diabetes need to test blood glucose levels with exercise and potentially adjust oral medications. Consider decreasing medication if blood glucose level is less than 80 mg/dL after exercise. For weight loss, plan the best time to exercise so that snacks can be avoided.

TABLE 12-3

Food Adjustments

Duration and Intensity	Blood Glucose (mg/dL)	Suggested Food Adjustment
<30 min of moderate activity. Examples: walking 1 mile or bicycling for <30 min	<100	1 fruit + 1 bread + 1 meat
	100–180	1 bread or 1 fruit
	>180	May not need snack
30–60 min of moderate activity. Examples: tennis, swimming, jogging, bicycling, yard work, or housework	<100	1 fruit + 1 bread + 1 meat
	100–180	1 bread or 1 meat
	>180–240	1 bread or 1 fruit
	>240	May not need snack
60 min of moderate- to high-intensity activity. Examples: competitive sports, strenuous bicycling, long-distance running, heavy shoveling	—	

If you are doing strenuous activity or playing sports, consult a physician or exercise physiologist for advice on blood glucose level management. Insulin adjustment may be required in addition to food adjustments (see Table 12-4). Blood glucose level should be tested hourly: 1 bread or 1 fruit per hour unless blood glucose level is 180 mg/dL or higher (snack may not be needed for that hour).

Box 12-10

Genomics

Type 2 diabetes accounts for most diabetes cases, and it is affected by both genetic and environmental factors. A recent meta-analysis examined the effect of the hemochromatosis gene (*HFE*) on the odds/risk of type 2 diabetes. Findings from 23 studies were included, of which 23 examined the C282Y variant and 18 examined the H63D variant. The meta-analytic data included 5528 individuals with type 2 diabetes and 6920 controls from a variety of countries, races, and ethnicities. The results from the meta-analysis showed that the H63D variant significantly increased the odds of having type 2 diabetes (OR 1.20, 95% confidence interval [CI] 1.03–1.41) in a comparison of individuals carrying the D allele with those carrying the H allele. In contrast, the C282Y variant was not significantly associated with diabetes risk (OR 0.96, 95% CI 0.82–1.12). In conclusion the authors

found that the H63D variant was associated with a moderate increase in the odds/risk of type 2 diabetes.

From Chen, L., Pei, J. H., Kuang, J., Chen, H. M., Chen, Z., Li, Z. W., et al. (2015). Effect of lifestyle intervention in patients with type 2 diabetes: A meta-analysis. *Metabolism: Clinical and Experimental*, *64*(2), 338–347.

Building a Rhythm of Physical Activity

Participation in regular physical activity increased gradually from the 1960s to the 1980s but seems to have plateaued in recent years. The progress made toward the *Healthy People 2020* physical activity goals indicates that most of the population has not embraced a physically active lifestyle (USDHHS, 2010). Although the benefits of physical activity are common to all people, patterns of physical activity differ among population subgroups defined by sex, age, racial background, income, and body fat. The following generalities are true:

- Men are more active than women.
- Physical activity declines with age.
- Ethnic minorities are less active than white Americans.
- Higher education and income are associated with more leisure-time activity.
- People who are obese are usually less active than their leaner counterparts.

Adherence and Compliance

Physiological, behavioral, and psychological variables all influence the decision to adhere to diabetes treatment, including physical activity and medications. Each person is unique, and success with exercise over the long term comes from recognition of personal motivation or core desire and support from the social environment. Core desire defines the purpose behind putting the effort into developing and maintaining an active lifestyle; it is what motivates the individual to exercise. People should be encouraged to spend some quiet time meditating on why being adherent is important to them.

Finding meaning and purpose in an active lifestyle can enhance behavior. Biopsychosocial and spiritual variables need to be considered in promoting physical activity. An individual's biopsychosocial factors and spiritual beliefs affect the behavioral and

attitudinal factors that influence the motivation and ability to adhere to an active lifestyle. Generally, however, physical activity is more likely to be initiated and maintained if the individual (Pentecost & Taket, 2011):

- Perceives a net benefit
- Chooses an enjoyable activity
- Feels competent doing the activity
- Feels confident in overcoming barriers that may interfere with the activity
- Feels safe doing the activity
- Can access the activity easily on a regular basis
- Perceives no significant negative financial or social cost
- Experiences minimal musculoskeletal discomfort
- Is able to address competing time demands
- Is readily able to fit the activity into the daily schedule
- Balances the use of labor-saving devices with activities that involve physical exertion

In addition, measures to increase satisfaction and increase adherence to medication use have been explored and include (García-Pérez et al., 2013):

- Complexity of dosing regimens: reducing the complexity of therapy by fixed-dose combination pills and less frequent dosing regimens
- Safety and tolerability: using medications that are associated with fewer adverse events (e.g., hypoglycemia or weight gain)
- Perceptions of medication: educational initiatives
- Care recipient-provider interaction: improved care recipient–health care provider communication
- Economic considerations: social support to help reduce costs

Educating the public about physical activity helps to provide guidelines for safe and effective exercise, to reinforce potential benefits, and to alleviate misperceptions that may interfere with the decision to change behavior. However, knowledge of exercise and the

intent to exercise do not correlate well with long-term compliance. Confidence in the ability to be physically active—and the confidence that overcoming barriers produces positive benefits that are related to personal goals (self-efficacy)—is strongly related to participation and compliance (Figure 12-5). Exercise self-efficacy is increased when people perform exercise successfully, receive positive feedback about success, view exercise role models, and learn more about the relationships among exercise, health, and body awareness (see the case study and care plan at the end of this chapter).

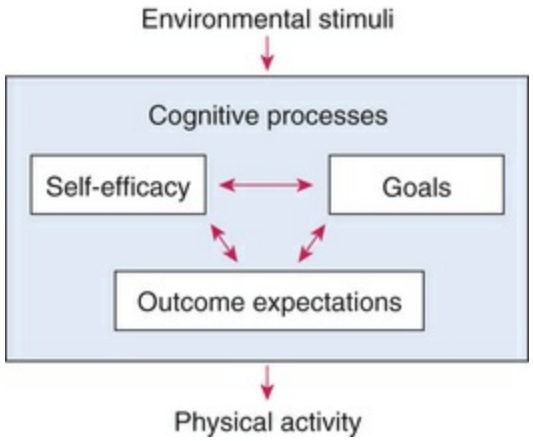

FIGURE 12-5 Three interacting cognitive processes of Bandura's social-cognitive theory. (Modified from Dzewaltowski, D. A. [1995]. Physical activity determinants: A social-cognitive approach. *Medicine and Science in Sports and Exercise, 26,* 1395–1399.)

Creating a Climate That Supports Exercise

Clearly exercise and fitness need to be social norms. A climate that supports and encourages physical activity should be fostered. Other people and organizations in the individual's social environment can influence the adoption and maintenance of physical activity.

Health Care Professionals

People are more likely to increase their physical activity if counseled

to do so by clinicians. Clinicians inquire about exercise habits, communicate the benefits of increased activity, assist the person in initiating activity, and provide adequate follow-up. Challenging perceived individual barriers to exercise and offering alternative viewpoints can help create new exercise paradigms (Lascar et al., 2014; Leone & Ward, 2013; Veldhuijzen van Zanten et al., 2015). Teixeira and colleagues (2012) published an informative systematic review that summarizes the evidence for self-determination theory, which can be used to improve our understanding of exercise motivation and the importance of autonomous regulations in promoting physical activity. Clinicians also serve as role models by demonstrating enthusiasm for and the health benefits of being physically active.

Recognizing the stages of behavioral change helps in meeting people at their stage of readiness to change behavior. Providing information on physical activity designed for specific stages of readiness enables people to move from stages of contemplation and preparation into action. An individual in precontemplation is not ready to actively change behavior. This person may respond better to support and information about the benefits of changing behavior rather than being placed in an action environment. The decision to change may come gradually. After an individual has made the commitment to change, the action phase lasts approximately 6 months. Continued follow-up throughout the action phase into maintenance is valuable in helping the individual stay committed until the termination phase is reached and the behavior is secure.

Family and Friends

Social support can be a valuable resource for behavioral change. Significant others or friends can serve as buddies, providing a source of companionship and motivation. These people can offer to share daily responsibilities to make time for exercise (e.g., provide child care). Parents can support their children's activity by having family outings and providing transportation, praise, and encouragement. Joining a fitness club or an exercise group at work provides various

forms of stimulation and socialization, which increases the potential for new friendships grounded in an appreciation of the rewards of exercise.

Schools

Schools are one of the most important resources for increasing physical activity. Strategies must be developed to facilitate increased activity in children because it is clear that children are becoming less active and more obese. Schools are providing less opportunity and poorer quality time for physical activity during school hours. All schools should provide opportunities for physical activity that:

- Are appropriate and enjoyable for children of all skill levels and are not limited to competitive sports or physical education classes
- Appeal to girls and boys and to children from diverse backgrounds
- Are offered daily
- Can serve as a foundation for activities throughout life

Schools can also serve as a resource for the community. Expanding operating hours at either end of the school day creates a safe, indoor environment for hall walking.

Communities

Participation in regular physical activity at the community level depends in large part on the availability and proximity of facilities and safe environments. Community government agencies, local health agencies, schools, and places of worship have the potential to provide activity resources to the population at large. Churches seem to be particularly successful in reaching ethnic minorities and older adults. Making neighborhoods safe for outdoor activities can have a major effect on improving activity habits, especially among low socioeconomic and disadvantaged populations, who report lower levels of daily physical activity.

Recognizing that many of the previous recommendations require a financial commitment, government agencies must respond to reports

by health agencies and establish public policies that support the importance of physical activity for the general population. Individuals should make a personal commitment to be physically active, but that commitment needs to be supported by a social and political environment that values this type of lifestyle choice.

Case Study

Exercise Self-Efficacy: Sharon G.

Sharon G. is a 53-year-old account executive who is 2 years after menopause, has insomnia, and has chronic low back pain and knee pain.

History: Motor vehicle accident (2012), resulting in bone graft to left leg (her left leg is shorter than her right leg). As part of rehabilitation, Sharon started jogging, which was more comfortable than walking with chronic right-sided sacroiliac joint pain. She started running marathons in 2014 and continued until 2015. In 2015 she began to add more variety to exercise and decreased her running, but she still identified herself as being an athlete.

In 2016 Sharon had a fall that resulted in chronic low back pain, and she was unable to continue aerobic exercise. She began to experience depression and insomnia; exercise had been a significant coping mechanism in the past, and now her whole sense of well-being was being affected. As Sharon attempted to rebuild her exercise practice, she would alternate between overexercising, exacerbating symptoms, and then having to stop and recuperate, reinforcing her negative self-image. Magnetic resonance imaging studies showed mild arthritis in her knees.

Reflective Questions

- What are some of her barriers to exercise?
- How will a regular practice of mindfulness and the relaxation response benefit Sharon's exercise practice?

- How would she benefit from cross-training?
- What exercise is she doing that is beneficial for helping to prevent osteoporosis?

Care Plan

Exercise Self-Efficacy: Sharon G.

***NURSING DIAGNOSIS: Altered sleep pattern related to low back pain, depression, and recent weight gain**

Medications

- Serax (oxazepam) 30 mg, four to six times a week
- Ginkgo biloba

Defining Characteristics

- Insomnia
- Chronic low back and knee pain
- Depression
- Upset about recent weight gain of 10 lb (61.5 inches, 118 lb); sees her ideal body weight as 108 lb

Expected Outcomes

- Walking, treadmill, bicycling, and low-impact aerobics (30 minutes, three to four times per week)
- Weights three to four times per week
- Stretching three to four times per week

- Daily relaxation response
- Build mindfulness into exercise practice

Interventions

- Treadmill and walking daily for 30 minutes
- Weights two to three times per week
- Yoga and stretching daily

Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

It is important that people incorporate increased activity into their lifestyles on a long-term basis; exercise in the short term is of little overall benefit. Helping individuals gain the knowledge (benefits of exercise and recommended parameters for exercise), skills (self-monitoring), and attitude (core desire) increases compliance. People need to be motivated enough to start the activity, enjoy the activity enough to want to continue, and appreciate the value enough to start again if they lapse. Lapses should be anticipated to avoid the unrealistic sense of total success or total failure. Behavioral change is cyclical rather than linear; success often comes with repeated movement through stages of change, and it helps to explore the reasons for the lapse and to view the lapse as a learning experience rather than a failure. The goal is to prevent a relapse that results in a more permanent noncompliance.

The benefits and enjoyment derived from a physically active lifestyle have a significant effect on the quality of life. However, this lifestyle is successful only when it is supported by a degree of self-awareness and self-care. People must realize that they are worth the effort of doing something good for themselves, that they have the right to be happy and healthy, and that exercise can help them achieve that end. By adding a mind-body component to physical activity and not regarding it solely as a physical regimen, people can experience true health rather than mere fitness. A great deal of body exercise is not required; 30 minutes a day can make a significant difference. Success comes with building a rhythm of physical activity into everyday life. The following are some suggestions for a lifestyle approach to exercise:

- Something is better than nothing.
- Attempt small changes over time (gradualism).
- Emphasize moderate intensity.
- Make activity an integral part of life.

- Focus on the process rather than the outcome.
- Clinicians can provide a knowledgeable, supportive, and enthusiastic environment to encourage the change to a healthier, more active way of life.

Stress Management

June Andrews Horowitz

OBJECTIVES

After completing this chapter, the reader will be able to:

- Analyze concepts of stress, stressor, eustress, and distress.
- Evaluate physical, psychological, social, spiritual, and behavioral stressors that are potential contributors to physical and mental health disorders.
- Analyze the pathophysiology of the stress response and effects on health and illness.
- Examine primary and secondary cognitive appraisals of stress.
- Develop evidence-based stress-management interventions that can be used in clinical practice.
- Explain the nurse's role in stress management and crisis intervention.

KEY TERMS

Active listening

Acupuncture

Affirmation

Anxiety sensitivity

Aromatherapy

Assertive communication

Burnout

Caregiver stress/burden
Cognitive restructuring

Think About It

Do We Live to Work or Work to Live?

When asked about yourself, what is your first response? Do you say what you do for work, or do you describe your characteristics? For most of us, our work roles, including being students, define us to a great extent. For most adults who live in industrialized countries and many other societies, employment is a primary source of income and social connection; working also contributes to a personal sense of accomplishment. However, how much work is too much? Americans take fewer yearly vacation days than their counterparts in other industrialized countries, and workplace pressures can increase the risk of a variety of disorders. Work-related stress can be a significant problem.

- What aspects of work typically create stress?

- How do people manage work-related stress? Which strategies are effective and which strategies increase health risks?
- How do people manage the work–home life balance **(spillover stress)**?
- What health-promotion strategies could you implement to reduce your own work-related stress?
- What could you do to promote workplace health in your own practice?

Stress is an excellent paradigm for understanding the relationships among the determinants of health, the leading health indicators, and health outcomes. Stress has been shown to cause or exacerbate many of the leading health problems in the United States today, such as those related to obesity, alcohol and drug abuse, poverty, and sexually transmitted diseases (US Department of Health and Human Services [USDHHS], 2011). Consequently, helping individuals, families, and communities to find more effective ways to respond to stress is an important health-promotion goal. The Centers for Disease Control and Prevention (CDC) healthy communities program works to support people in making healthy choices where they live and work (CDC, 2012a).

Stress management has been an effective intervention framework for health promotion, disease prevention, and symptom management. Stress-management strategies such as relaxation and imagery, self-monitoring, **goal setting**, cognitive restructuring, **mindfulness**, and problem-solving have long been staples of community health-promotion programs, including Alcoholics Anonymous, Smokenders, YMCA (Y-USA), and Weight Watchers. These strategies help people to modify health risk behaviors and thereby improve quality of life. However, national health data (CDC, 2012b) indicate the need for continued and expanded use of these modalities across the life span. Although the United States health care system provides excellent, expensive, heroic care, it provides poor-quality low-cost health-

promotion/preventive care, including stress management. Moreover, to ameliorate many harmful effects of stress, community-level health promotion is essential. Although shifting focus from providing acute care for individuals to enhancing the health of communities requires a revolution in our health care delivery systems and outlook, successful community health-promotion initiatives hold promise for the future (Fawcett & Ellenbecker, 2015).

The goal of stress management is to improve quality of life by increasing healthy, effective **coping**, thereby reducing unhealthy consequences of distress. This process produces a dynamic interaction of mind, body, and spirit, which influences physical health and well-being. Stress management is thus an essential tool for expert nursing practice, which recognizes the interface of knowledge on behavior change. The use of critical reasoning to examine multiple factors contributing to symptom development provides a valuable contribution to meeting the goals of *Healthy People 2020.* Stress management can have a significant impact on the following leading health indicators in *Healthy People 2020:* physical activity, obesity, tobacco use, substance abuse, responsible sexual behavior, mental health, injury and violence, environmental quality, immunization, workplace wellness, and access to health care (USDHHS, 2011). (See Chapter 1 for additional discussion of *Healthy People 2020.*) This chapter outlines the multifaceted psychophysiological aspects of stress, examines strategies shown to mediate its harmful effects, reviews examples of clinical situations in which stress management has been effective, and explores the unique perspective nurses bring that helps individuals identify healthy stress-management strategies.

Sources of Stress

A **stressor** is any psychological, social, environmental, physiological, or spiritual stimulus that disrupts the tendency of a system, especially the physiological system of higher animals, to maintain internal stability, owing to the coordinated response of its parts to any situation or stimulus that would tend to disturb its normal condition or function. Although in use for more than 100 years, the term has suggested balance and stability but has also denoted interchange and continuous regulated or balanced change (Bortz, 2015). In other words, **homeostasis** has connoted a state of balance thereby requiring change or adaptation—not a static state (Figure 13-1). To reflect advances in science that underscore the continuously changing nature of and interaction among life processes in all of its manifestations, the term **homeodynamics** has emerged in the past decade (Bortz, 2015) as a better descriptor:

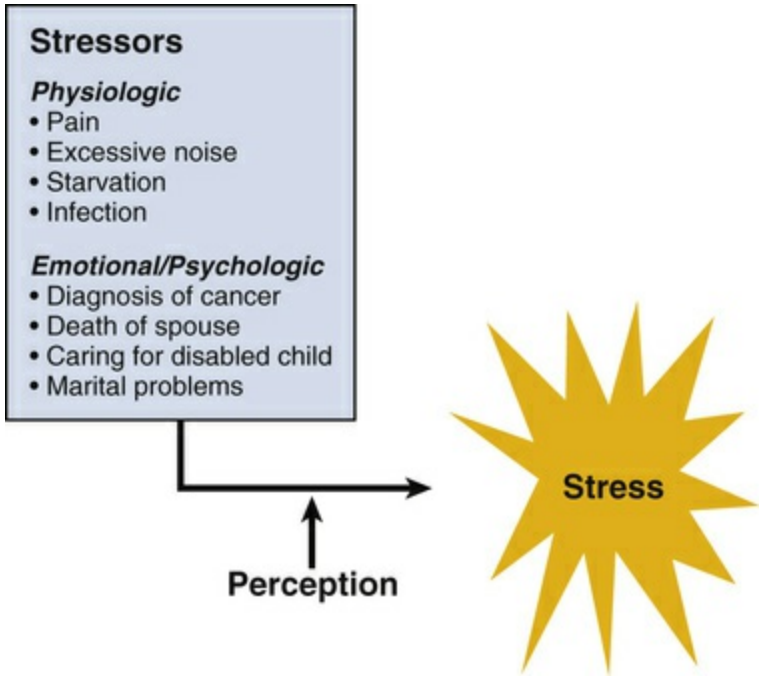

FIGURE 13-1 Stressors can be physiological or emotional/psychological. Perception of the stressors will

determine whether they cause stress. (From Lewis, S. L., Dirksen, S. R., Heitkemper, M. M., & Bucher, L. [2014]. *Medical-surgical nursing: assessment and management of clinical problems* [9th ed.]. St Louis: Mosby.)

Homeodynamics extends homeostasis into a more inclusive term. It is evident that there is no stasis in life. All of life is dynamic. 98% of a body's atoms are replaced each year. The Krebs cycle turns over 2.66×10^21 times per minute. The half-life of an intestinal cell is measured in days. Stasis is nowhere to be found. Life is a verb rather than a noun.

Then stress is understood as a state of threatened homeostasis/homeodynamics that triggers an array of adaptive physiological, behavioral, and even social responses in an effort to reestablish homeostasis or relative balance to avoid chaos. These descriptions of stress underscore important ideas: even welcome events, such as a child's wedding, are stressors because they precipitate change. Nonetheless, stress is not intrinsically bad or unhealthy, and stress is experienced psychophysiologically and socially (i.e., as an *interplay* across all domains of individual and communal living). Stress is an essential component of being alive. Stress can be situational or maturational. One's coping strategies and resources will determine the outcomes of each stressful experience. Moreover, family and communal/social response will also affect many responses to shared stress. In this age of instant messaging and 24/7 news cycles, the communal shared nature of stress is intensified.

Individuals encounter a variety of physical, psychological, social, spiritual, and environmental stressors. These stressors are not simply an additive but rather have an interactive effect within a homeodynamic human-ecological system. Stressors range from health and illness experiences, such as childbirth, physical illness, trauma, or blood loss, to activities of daily living, such as caring for children, meeting work deadlines, and cleaning or repairing the house, to less common events, such as taking a critical examination, experiencing the death of a relative, losing possessions in a fire, losing a job, getting

a divorce, or getting married, and environmental contexts. As a useful rubric, stressors can be organized into three categories: stressors over which people have no control (extrinsic factors), such as the weather, a traffic jam, or the death of a spouse; stressors that individuals can modify by changing their environment, social interactions, or behaviors; and stressors created or exacerbated (intrinsic factors) by poor time management, procrastination, poor communication, catastrophic negative thinking (expecting the worst), or struggling with self-defeating behaviors. However, stressors can never be neatly boxed into simple categories: Stress is a person-environment process. The person-environment fit model indicates that the person appraises a situation as taxing or as exceeding his or her resources and endangering well-being. Moreover, links between biological pathways and social adversity to subsequent adverse health outcomes underscore the importance of stress as a health determinant (Berger et al., 2015; Lazarus & Folkman, 1984; Weber, 2011).

Stress appraisal is an important concept that helps to explain why two people react in different ways to the same situation. In addition, models of stress have evolved from an individualistic perspective to consideration of family-level and community-level stress and coping (Weber, 2011).

The shared situation of Ms. Hernandez (86 years old) and Ms. Goldman (86 years old), both in good health, provides a case in point. Both individuals are about to become new residents at an assisted living retirement community in their hometown. Ms. Hernandez perceives this move as an opportunity to increase the ease of her socializations and activities of daily living, and is looking forward to making new friends and participating in new recreational activities. In contrast, Ms. Goldman views this move as abandonment by her family and fears that the available resources will be inadequate. Although the event is virtually the same for both Ms. Hernandez and Ms. Goldman, the homeodynamic consequences are personalized because each woman perceives her situation differently. Even though the move to

the new environment is the same, each woman has different coping styles and each has different support systems, so the experience will differ in its perception and thereby its level of stress.

Stress is the physical, psychological, social, or spiritual effect of life's pressures and events. Stress is an interactive hemodynamic process that involves appraisal and response to loss or the threat of loss of well-being at individual, family, and community levels (Weber, 2011). Canadian physiologist Hans Selye (1950, 1974, 1982) first introduced the general adaptation syndrome, which led the way to continual interest in stress and the effect on the body. Selye reported that, to a certain extent, stress can be challenging and useful, which he identified as **eustress**. Selye also observed that when stress becomes chronic or excessive, the body is unable to adapt and maintain homeostasis, and thus the process becomes **distress**. Stress can be both useful and harmful. As stress increases, efficiency and performance also increase, but not endlessly. At a certain point performance and efficiency start to decrease significantly if stress continues unabated. It is important to understand the many causes of stress and the negative physical, psychosocial, and spiritual consequences of distress. Understanding the many-sided sources of stress provides the rationale for a multifaceted approach to its management. It is noteworthy that even in its early understanding, scientists and clinicians recognized the dynamic changing nature of stress and its many human system responses (Box 13-1).

Box 13-1

Relationship Between Stress and Development of Breast Cancer and Survivorship

Nurses appreciate the multiple factors in the development of breast cancer and other diseases. Researchers exploring the relationship between stress and breast cancer have demonstrated a relationship among stress (personality traits, stressful life events, and responses to stress), the immune system, genetics, and environmental factors. The

physiological influences of stress on breast cancer may be mediated by the immune system. Although women may be unable to prevent stress in their lives, they can learn stress-management strategies. Dealing positively with stress may improve the quality of life for individuals and their families with or at risk of breast cancer.

Growing research evidence supports this understanding of the complex interactions between life stress and breast cancer risk. For example, Kruk (2012) examined the relationship between severe life events and breast cancer risk. Kruk used case-control examination of 858 Polish invasive breast cancer patients and 1095 controls matched for age and place of residence. Data on life events, sociodemographic characteristics, reproductive factors, family history of breast cancer, current weight and height, and lifestyle habits were collected via a self-administered questionnaire. Unconditional logistic regression analyses with odds ratios with 95% confidence intervals were estimated. After adjustment for potential breast cancer risk factors, women with four to six individual major life events had 5.33 times higher risk of breast cancer compared with those in the lowest quartile. Similarly, women with a high lifetime life change score had approximately five times higher risk compared with women with corresponding scores in the lowest range. Several life events (death of a close family member, personal injury or illness, imprisonment/trouble with the law, retirement) were significantly associated with breast cancer risk. Those findings suggest that major life events may have an important etiological role in the development of breast cancer. Surviving breast cancer also poses ongoing challenges to women who experienced breast cancer and their partners (Gregorio et al., 2012).

From Gregorio, S. W., Carpenter, K. M., Dorfman, C. S., Yang, I. L. C., Simonelli, L. F., & Carson III, W. E. (2012). Impact of breast cancer recurrence and cancer-specific stress on spouse health and immune function. *Brain, Behavior, & Immunity, 26*(2), 228–233; Kruk, J. (2012). Self-reported psychological stress and the risk of breast cancer: A case-control study. *Stress, 15*(2), 162–171; National Cancer Institute. (n.d.). *Psychological stress and cancer: Questions and answers.* http://www.cancer.gov/cancertopics/factsheet/Risk/stress.

In nursing we have operated within multiple frameworks to

understand stress and its outcomes. Historically nursing has been grounded in the biological and medical sciences because of our long-standing roles in health promotion and caring for people experiencing illness. Yet over many decades nursing frameworks have also embraced concepts of continuous change and interaction in human-environmental fields. Most notably Martha Rogers's science of unitary human beings (Phillips, 2015; Willis et al., 2015), Neuman's systems model, and Roy's adaptation model (Willis et al., 2015) have stressed the dynamic, interactive nature of human life. As a result, nurses have learned to balance and integrate the worldviews of traditional medical and bench science with the evolving and sometimes rather heretical nursing frameworks that focused more on continual change and interaction within and among human-environmental systems. Thus in this chapter, examining stress, its manifestations, and approaches to ameliorate distress and associated health problems involves weaving knowledge and understanding generated from diverse and sometimes conflicting perspectives.

The models for understanding human stress are multifaceted and complex. In the past, scientists and clinicians tended to examine and understand stress from their own disciplinary or scientific silos. In other words, understanding stress was typically split into neurobiological and psychosocial camps. However, in recent decades **"sociophysiology"** has emerged as a multidisciplinary perspective to integrate the "social" and "biological" worlds and answer the following question (Barchas & Barchas, 2011): "How do social processes impact the physiology of the organism and how does that altered physiology affect future social behavior?"

Nursing science has long held an interest in the dynamic interaction among human systems. Outstanding among nurses' voices calling for innovative perspectives to topple the traditional and accepted mechanistic, medical worldview was Martha Rogers's theory of unitary human beings (Phillips, 2015). Phillips, a valued colleague of Rogers, described her as a heretic and heroine because of her then revolutionary view about nursing and health and illness. Today her ideas resonate well with contemporary understandings of the rapidly

evolving interplay across all spheres of human life.

Thus understanding stress and its management involves attention to the *interactions* of social and biological life at individual and family/communal levels. It follows that stress-management strategies/interventions need to be multifaceted and could be aimed at neurophysiological and interpersonal/social stressors and/or interactions and responses. Establishing empathy by the nurse in understanding stress is beneficial in designing interventions aimed at primary, secondary, and tertiary levels of prevention.

Physical, Psychological, Sociobehavioral, and Spiritual/Homeodynamic Consequences of Stress

To begin, it is necessary to set the groundwork for understanding stress and its multifaceted/interactive consequences. In the discussion that follows, facets of human responses are artificially categorized and discussed to assist the learner to discern the many aspects of stress responses. In no way should this content be interpreted as meaning that stress responses are isolated to specific human systems or simply additive. Growing understanding of the homeodynamic interplay, including epigenetics, within individuals and across human and ecological systems forces us to examine the ever-changing nature of our knowledge of our world. As a startling example, in 2016 the Zika virus emerged on the global stage to pose multiple human health risks, with a specific threat to pregnant women and their fetuses for microcephaly, a devastating birth anomaly: the effects reverberated across continents with lightning speed and had global effects on health, travel, and prevention efforts (Sifferlin, 2016). Thus we all must remain cognizant of the ongoing interplay within and among human, social, and ecological systems, even as we examine knowledge focused predominantly at specific response areas (i.e., human systems). Nevertheless, understanding stress effects at a variety of micro to macro levels is needed to comprehend a holistic picture. The future challenges to do so are indeed exciting!

Physiological Effects of Stress

An individual's homeodynamic response to stress provides a model to examine changes across biopsychosocial-spiritual domains. In response to a perceived threat (i.e., stressor), the body prepares to meet the challenge. Perception of threat stimulates a physiological

pattern of neuroendocrine activation and behavioral changes mediated by the central nervous system. Moreover, chronic stressful life circumstances likely exacerbate conditions favorable to adverse heath outcomes (Figure 13-2) (Berger et al., 2015). Nonetheless, in most cases this reaction is an adaptive, short-term, acute response to a stressor. First termed the **fight-or-flight response** (Cannon, 1914) and later called the **stress response** (Selye, 1950, 1974, 1982), the individual's reaction to a real or imagined threat prepares the body for emergency reaction and fosters survival in circumstances of immediate, time-limited threat. The hypothalamus signals the sympathetic nervous system to release epinephrine and norepinephrine, along with other related hormones. A resultant state of arousal is characterized by increased metabolism, pulse rate, blood pressure, respiration rate, and muscle tension. This physiological arousal proceeds along three main pathways: the musculoskeletal system, the autonomic nervous system, and the psychoneuroendocrine system.

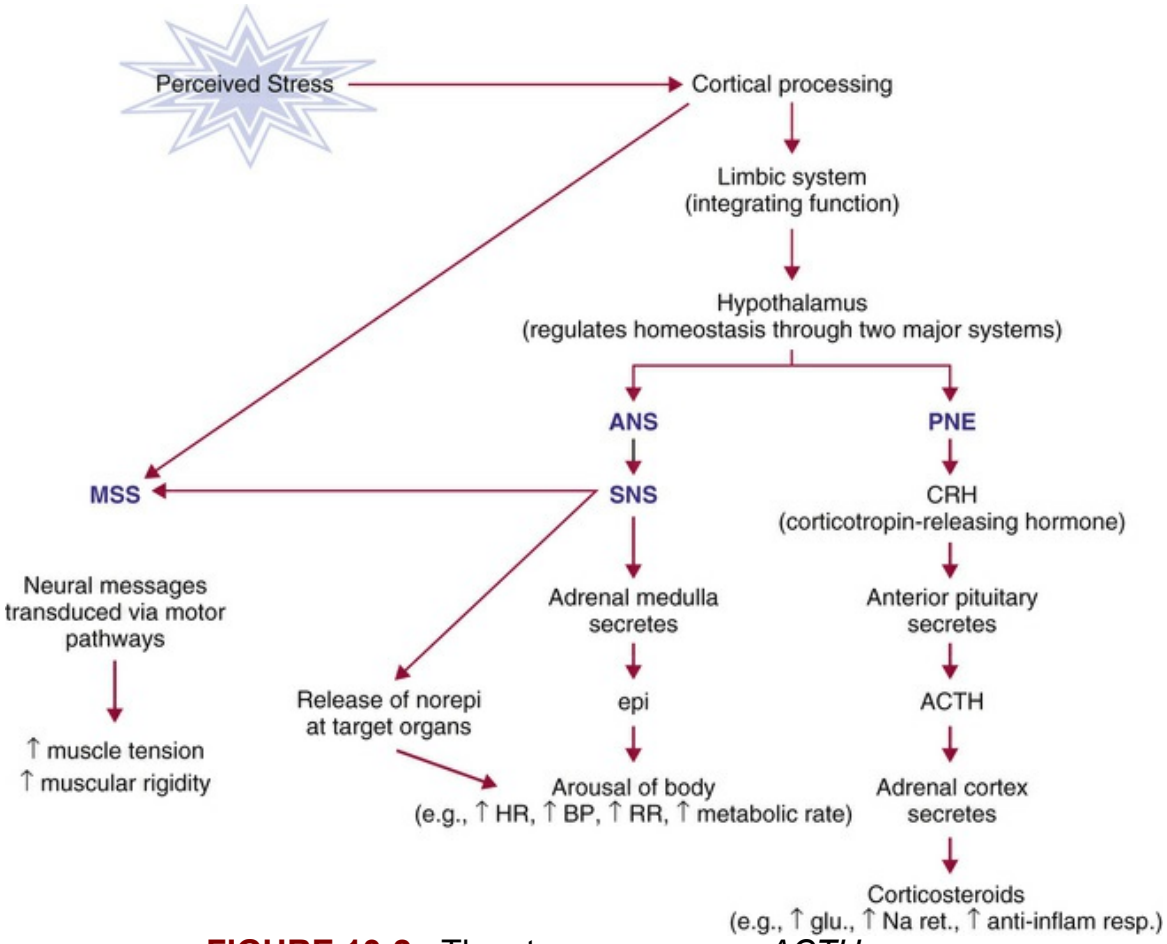

FIGURE 13-2 The stress response. *ACTH,* Adrenocorticotropic hormone; *ANS,* autonomic nervous system; *anti-inflam resp.,* antiinflammatory response; *BP,* blood pressure; *CRH,* corticotropin-releasing hormone; *epi,* epinephrine; *glu.,* blood glucose level; *HR,* heart rate; *MSS,* musculoskeletal system; *Na ret.,* sodium retention; *norepi,* norepinephrine; *PNE,* pituitary-neuroendocrine system; *RR,* respiration rate; *SNS,* sympathetic nervous system. (From Wells-Federman, C., Stuart-Shor, E., Deckro, J., Mandle, C. L., Baim, M., & Medich, C. [1995]. The mind/body connection: The psychophysiology of many traditional nursing interventions. *Clinical Nurse Specialist, 9,* 60.)

The musculoskeletal system responds by increasing tension and tone. At the same time, the autonomic nervous system, via the sympathetic branch, orchestrates a generalized arousal that includes increases in heart rate, blood pressure, and respiration rate. Additionally, a heightened awareness of the environment is triggered, and blood shifts from the visceral organs to the large muscle groups.

Concurrently the psychoneuroendocrine system stimulates the hypothalamic-pituitary-adrenal axis and the secretion of corticosteroids (primarily cortisol) and other neuroendocrine substances into the systemic circulation, increasing blood glucose levels, influencing sodium retention, and, in the acute phase, increasing the antiinflammatory response.

Study findings (CDC, 2012b) have shown that maladaptive stress can cause or exacerbate disease or symptoms of diseases. Proinflammation associated with stress is emerging as a common pathway in a variety of diseases, such as asthma, angina, cardiac arrhythmias, pain, tension headaches, insomnia, depression, and gastrointestinal disorders. Additionally, stress can produce hyperreactivity or hyporeactivity of hormones regulated by the psychoneuroendocrine system (Bonfiglio et al., 2011).

As mentioned previously, in most cases the stress response is a beneficial adaptive pattern that increases the efficiency and quality of performance, but it can prove maladaptive when a stressor continues indefinitely. Maladaptive stress (distress) is an enduring and sometimes self-sustaining cascade of responses that degenerate physical, psychosocial, and spiritual well-being. Not surprisingly, stress and specifically depression have been associated with increased susceptibility to cardiovascular disease, as well as poor response to its treatment. Inflammation has been suggested as one of the processes underlying the association between cardiovascular disease and depression, two debilitating conditions (Nikkheslat et al., 2015). Nonetheless, indirect influences of stress and depression on self-care health behaviors also help to explain associations between these diseases. Needless to say, further investigation is needed to demonstrate direct causal links, as well as effectiveness of psychological interventions, for people with cardiovascular disease (Whalley et al., 2011).

Psychological Effects of Stress

The psychological effects of stress are best illustrated by its contributory role in negative mood states, including anxiety,

depression, hostility, and anger. Exposure to stressful stimuli is associated with elevated cortisol levels and resultant effects on the immune system. The duration, intensity, and timing of a stressor have been shown to affect immune responses in animals. Although systematic studies to explain different patterns of immune response with humans are not yet adequate, the interactive nature of the mind and immune system is an exciting area of investigation that may contribute to future evidence-based practice (Hou & Baldwin, 2012).

A growing body of clinical research outcomes illustrates the interplay of stress and various health outcomes. For example, research evidence is convincing that individuals with eating disorders experience a high rate of stress, and that appraisal is more important than the nature of any stressful event itself (Courbasson & Jeyarajan, 2011). The relationship between stress and cardiac symptoms also is well documented. Closa and colleagues (2010) demonstrated that for individuals awaiting angiography, stress and lack of social support predicted self-reported cardiac symptoms, regardless of actual disease severity. Clinical implications include reducing perceived stress and ruminative, angry coping styles by encouraging reappraisal and support seeking. In conclusion, the evidence to date demonstrates a strong association between chronic stress and negative health effects for individuals and their family members.

Sociobehavioral Effects of Stress

In response to stress, individuals often revert to or increase their reliance on less healthy behaviors, such as overeating, excessive use of alcohol or drugs, and smoking. Recognizing that such behaviors are inconsistent with the healthy behaviors needed to cope with stress is easy; however, stopping these behaviors and using health-promoting strategies instead is not. Risky behaviors and traits such as a sedentary lifestyle, obesity, overeating high-fat foods, smoking, substance abuse, and social isolation have been linked to morbidity and mortality (USDHHS, 2011). Conversely, **exercise**, **healthy diet**, smoking cessation, healthy weight maintenance, and social interaction have been identified as leading indicators of health in the United States

(USDHHS, 2011). Encouraging these health behaviors supports the goals of *Healthy People 2020.* However, unless we understand how psychosocial factors affect health behaviors, promotion of effective self-care is an unrealistic goal (Box 13-2: *Healthy People 2020*).

Box 13-2

Healthy People 2020

Health-Related Quality of Life and Well-Being

Health-related quality of life (HRQoL) is a "multi-dimensional concept that includes domains related to physical, mental, emotional and social functioning." HRQoL is a new topic in *Healthy People 2020* and goes beyond "direct measures of population health, life expectancy and causes of death, and focuses on the impact health status has on quality of life. A related concept of HRQoL is well-being, which assesses the positive aspects of a person's life, such as positive emotions and life satisfaction." As explained in this chapter, stress is a challenge to HRQoL. Stress management is a key strategy to improving HRQoL.

From US Department of Health and Human Services. (2014). *Health-related quality of life & well-being.* http://healthypeople.gov/2020/topicsobjectives2020/overview.aspx?topicid=19.

Spiritual Effects of Stress

Interest in the connection between spirituality and health is significant. Spirituality is defined in many ways, but key components are typically that spirituality comprises feelings, thoughts, experiences, and behaviors that arise from a search for meaning and may include interconnectedness with self, others, nature, and a higher force called God, a life-force/higher power, nature, or the transcendent. Spirituality and religion intersect for many, yet they are not synonymous. Many individuals feel spiritual without a formal religious affiliation or practice. In response to stress, people often feel disconnected from life's meaning and purpose; harmful effects on

their health and well-being can result. Stressful events can shatter individuals' spiritual center or conversely can move individuals to seek comfort in spirituality or religious practice, beliefs, or community. Encouraging involvement with one's religious/spiritual practices is recommended as a helpful intervention for stress-related problems (Weber, 2011).

Examination of spiritual healing in the aftermath of men's childhood mistreatment through nursing research unearthed the following themes (Willis et al., 2015):

- Exploring spiritual faith traditions as a foundation for spiritual healing
- Being in spiritual community serves as a foundation for spiritual healing
- Being in spiritual community facilities healing connections with other human beings and the transcendent
- Cultivating spiritual consciousness through prayer, music, yoga, nature, and reading spiritual material expands awareness of one's spiritual being
- Loving and letting go reflects one's spirituality and humanity
- Believing in a cosmic energy, divine purpose, or higher power can bring a sense of healing

These themes provide foundations for nursing interventions to be tested (Willis et al., 2015). Engaging a pastoral counselor of the individual's choice in the treatment team can be an effective strategy to promote spiritual healing. However, the source of mistreatment must be carefully explored sensitively with the individual in advance to determine the acceptability of engaging a member of the clergy.

The previous section discussed how stress can adversely affect biological, cognitive, emotional, behavioral, and spiritual well-being. This understanding of the psychophysiology of the mind-body-spirit connection is fundamental to the application of stress management in nursing and provides an obvious rationale for a multifaceted approach. Further support is provided from research endorsing the health-promoting effects of managing stress (Gregorio et al., 2012)

(Box 13-3: Research for Evidence-Based Practice).

Box 13-3

Research for Evidence-Based Practice

Impact of Breast Cancer Recurrence and Cancer-Specific Stress on Spouse Health and Immune Function

Spouses of people with cancer are often primary informal caregivers for their partners. As a group, they experience a variety of poor health outcomes. This study examined the relative contributions of cancer recurrence—a cancer-specific stressful event—and the subjective experience of cancer-specific stress in a sample of male spouses of breast cancer survivors. The investigators hypothesized that stress would contribute to poorer physical health and compromised immune function. Given the difficulty of random assignment for this type of study, the researchers used a matched-control design, comparing spouses of women with recurrence to a cohort of spouses whose wives were disease-free but had a history of breast cancer. Spouses of women experiencing a first recurrence were matched to spouses of women with no evidence of disease. The results showed that cancer recurrence status was not a significant predictor of spouses' physical health or immune function; however, among all spouses, cancer-specific stress symptoms were associated with increased physical symptoms and altered T-cell blastogenesis. These findings suggest that health effects for these caregiving spouses were more strongly connected to their subjective experience of cancer as stressful, rather than their partners' current disease status. A practice implication is that exploring spouses' appraisals of the experience should be an essential component of family care when one partner has breast cancer.

spouse health and immune function. *Brain, Behavior, & Immunity, 26,* 228–233.

Health Benefits of Managing Stress

A growing body of evidence underscores the importance of controlling stress to promote health and quality of life for people with a variety of health problems. "The association between stressors and biomarkers specific to physiological systems (i.e., cardiovascular, neuroendocrine, immune, etc.) is an emerging area of interest in biomedical research…with evidence that specific stressors may differentially affect various physiological systems" (Paradies, 2011). Thus interventions that reduce the stress response are an important component of comprehensive disease prevention and management. Psychotherapeutic approaches, such as interpersonal and cognitive-behavioral psychotherapies that focus on perception and management of life stressors, are effective treatments for depression and related mental health disorders (Sadock & Sadock, 2015). These psychotherapies have been incorporated into a range of treatment and secondary prevention programs, such as cardiac rehabilitation, with great potential for wider adapted use (Menezes et al., 2011). Targeting primary prevention programs is the aim of nurses in assisting individuals with stress reduction before becoming symptomatic.

Promoting a positive attitude and development of skills to cope with stress is foundational to many stress-management interventions. As early as 1982, Kobasa and colleagues (1982) made a groundbreaking contribution to our understanding of the stress-illness relationship when they identified characteristics of hardiness. They described individuals with stress-hardy characteristics who, when exercising and accessing **social support**, were less vulnerable to stress-related symptoms and diseases. The characteristics of stress hardiness are control, challenge, and commitment. For stress-hardy individuals, stress is viewed as a challenge rather than a threat; they feel in control of situations in their lives, and they are committed to rather than alienated from work, home, and family. Hardiness continues to be assessed (recognized) by nurses in assisting individuals and families dealing with a crisis and promoting the

strengths of survivorship in dealing with new stressors. Another term that is used is resiliency.

Stress management is especially important in situations such as caregiving that extend over long periods. **Caregiver stress/burden** can be described as the appraisal of the experience of caregiving including the taxing nature of behaviors of the recipient of care, role conflict or strain, and physical and mental health effects on the caregiver (McLennon et al., 2011). As the setting for care increasingly is the home and family members take on mounting responsibility for care of loved ones (i.e., children, spouses, or aging parents with chronic conditions), the importance of caring for the caregiver to prevent significant **burnout** grows. As a result of current trends of delayed parenting and increased life span, the **"sandwich generation"** of middle-aged adults who have concurrent responsibility for their children and aging parents is at particular risk of severe caregiver burden. Research evidence supports the usefulness of interventions aimed at helping caregivers to find meaning in their activities and role in buffering caregiver stress (McLennon et al., 2011; Quinn et al., 2011; Wood et al., 2015). Moreover, the quality of the caregiver–care recipient relationship can affect the caregiver's well-being (Quinn et al., 2011).

In summary, the evidence is conclusive that thoughts, feelings, behaviors, beliefs, and biological activity are interrelated. Perceptions, or the way individuals view situations, can lead to stress and, in turn, adversely affect biological activity, emotions, behavior, and the connection with life meaning and purpose. This interaction among perceptions, stress, and multifaceted effects, in turn, can increase stress and foster a negative stress cycle. The remainder of this chapter presents assessment of stress relating to the homeodynamic framework, including the facets of physical, psychosocial, and spiritual health and well-being of individuals, and describes the application of a variety of strategies shown to help break the negative stress cycle and mitigate its harmful effects across the biological, psychosocial, and spiritual domains.

Assessment of Stress

Assessment of the stress-coping abilities of an individual, family, or community is part of a comprehensive health assessment that includes past and present subjective and objective data. Collection of these data enables the individual and the nurse to determine the status of the person's stress-coping pattern, and actual and potential strengths and weaknesses.

The nurse thoroughly collects data during the history, physical examination, and health patterns assessment (see Chapters 7–9). Identifying the stress-coping pattern is especially important. Asking for specific examples of events with probes to elicit the person's thoughts, feelings, and actions leads to discussion of appraisal and ideas for alternative actions in the future (see Chapter 4, Box 4-12 and Figure 4-4). Each individual is the primary data source; no other person can explain accurately the individual's perceptions of the stressors, stress responses, and resources to prevent or alleviate the stress.

Stress is experienced across biological, psychosocial, and spiritual domains; therefore all perceptions are important for the assessment. Throughout the assessment process, individuals may become aware of information of which they were previously unaware, or they may identify information related to their perceived problems. For example, a man may be aware of the stress of his job but may be unaware that his high blood pressure was caused at least in part by this stress.

Lazarus and Folkman (1984) proposed a theory comprising primary and secondary appraisals of stressful events, situations, or demands and the effectiveness of an individual's coping skills. **Primary appraisal** of coping includes descriptions of perceived actual and potential positive and negative outcomes. Negative outcomes refer to harm, whereas positive outcomes refer to the challenges resulting from stressors that an individual perceives can be overcome. Examples of negative outcomes include physical injury; disease; loss of a cherished relationship, position, or possession; and death.

Positive outcomes include graduation, promotion, and development of important relationships (see the case study and care plan at the end of this chapter).

Secondary appraisal follows primary appraisal. Secondary appraisal consists of the individual's identification of choices to cope with the actual or potential harm, threat, or challenge. The choices may be internal or external resources and responses. For example, a social resource in coping with the needs of a toddler might be learning strategies in a parent-effectiveness training course. A coping response to the challenges of parenting a toddler might be restructuring the toddler's and parent's schedules to allow for more frequent cycles of activities and rest.

The individual's primary and secondary appraisals of stress provide opportunities to consider the stress experiences in different ways. Resources that had been forgotten may be remembered, or a threat may be newly viewed as a challenge and an opportunity for enhanced development and status. The appraisal process mediates stress responses. This understanding supports use of cognitive-behavioral therapy (CBT) as an effective intervention approach for stress-related problems (Wood et al., 2015). Nurses appropriately may refer individuals for CBT and are also encouraged to obtain advanced training in CBT to integrate this evidence-based intervention into their practice. Use of good-quality health texts aimed at the general population is also an effective psychoeducational approach. For example, Marchant's (2016) highly readable book *Cure: A Journey Into the Science of Mind Over Body* and Kaku's (2014) interesting text *The Future of the Mind* are examples of materials that can serve as springboards for discussion of ways to adjust the meaning of life stressors, responses, and ways to cope.

Measuring stress and related symptoms/responses is important in assessment and evaluation of treatment outcomes. By using measurement instruments with established reliability and validity, nurses can improve assessment of an individual's stress and coping. Tools can help nurses distinguish between diagnoses that have many signs and symptoms in common. For example, disturbances in

thinking and feeling processes can be difficult to distinguish and may have confounding clinical pictures. These disturbances can occur separately or simultaneously in the same person. An example of this complexity is the overlapping symptoms of depression and dementia. The nurse determines whether one health problem is actually the cause of the other so as to develop an effective plan of care (see the case study and care plan at the end of this chapter).

A wide variety of instruments are available to help nurses assess orientation, attention, cognitive skills and patterns, traits and states of emotions, symptoms of mental health distress and disorders, and overall quality of life. For example, the Schedule of Recent Experiences (Holmes, 1981) and the Impact of Event Scale (Horowitz et al., 1979) are two well-established instruments used widely in clinical assessment and research to measure stress associated with life changes and events. Burnout, be it work related or personal, is understood as emotional exhaustion, depersonalization, and a sense of reduced personal accomplishment. The Maslach Burnout Inventory (Maslach & Jackson, 1986) is a psychometrically robust instrument to assess perceptions about work-life balance. Before using any instrument, clinicians and researchers need to check information about its reliability and validity, updates/revisions, training requirements, and copyright restrictions (e.g., purchase requirements) that can affect access to its use. Older instruments typically have a long-established record of demonstrated reliability and validity; however, phenomena may evolve with time, and revised versions may have been developed and tested for specific populations. Therefore exploration of the literature to seek updated information to inform use is always wise. Additionally, the seeking of consultation from clinical experts/researchers regarding instrument selection is recommended.

Use of standardized instruments promotes accuracy in developing diagnoses and care plans and assists in evaluating the effectiveness of care. For example, a nurse may compare an individual's self-evaluation and/or symptom preintervention scores with postintervention scores and revise the care plan accordingly.

Additionally, nurses may analyze population baseline scores for relevant characteristics and develop programs of research and quality improvements aimed at improving outcomes.

Assessment at the family and community levels is also recommended. Family assessment consists of three major categories: structural, developmental, and functional components of the family (Wright & Leahey, 2013). Environmental factors also contribute to the determinants of health and thus to stress, so a thorough nursing assessment requires consideration of the community. For example, examination of community-level data for unemployment, population density, housing, school quality, crime, suicide incidence, and disease occurrence patterns (i.e., health profiles of the community), as well as availability of various amenities such as green space and access to transportation and healthy foods, provides a more complete stress assessment than does individual assessment alone (DeMarco & Segraves, 2011). Moreover, family and community assessment can point to possible stress-reduction interventions, such as marshaling available social support or engaging in outdoor activities and exercise.

Stress-Management Interventions

Stress-management strategies are beneficial to people across a broad spectrum of chronological, gender, cultural, and ethnic characteristics. Men and women, young and old, from divergent socioeconomic, cultural, and ethnic backgrounds can benefit from stress-management interventions. Sensitivity to the needs and values of individuals and communities, particularly for high-risk groups (i.e., vulnerable populations), guides assessment and intervention techniques. The language, belief system, and cultural distinctions of individuals and families in the community guide the choice and adoption of stress-management strategies. Understanding stress and its management involves attention to the *interactions* of social and biological life at individual and family/communal levels (Barchas & Barchas, 2011); therefore interventions may need to encompass a variety and combination of psychosocial and biological approaches at the primary, secondary, and tertiary levels of prevention. Population-based interventions may be expanded from the individual to the community and to a system- or population-focused practice (Harkness & DeMarco, 2012).

Developing Self-Awareness

Self-awareness is one of the most effective stress-management tools. Self-awareness helps people learn about interactions among mind, body, and spirit; increases a sense of control; and counters self-defeating perceptions. Interventions that promote self-awareness help people make sense of life events and circumstances that may be bewildering or discomforting. Many experiences in life lead to feelings of emptiness and disharmony because people are unable to connect the experience with thoughts, feelings, actions, and physiological responses. Self-awareness helps individuals recognize stress that they create through negative, exaggerated, unrealistic thinking. This recognition affords an opportunity to change these

negative thought patterns, thereby decreasing stress and increasing control. Strategies that increase self-awareness can empower individuals to make new connections and to reframe and reinterpret their experiences in light of their own inner strengths and wisdom.

A closely related concept is mindfulness, nonjudgmental self-awareness characterized by intentional acceptance of the unfolding of experience in the moment. Mindfulness can be understood as having two components: "the intentional self-regulation of attention so that it remains focused on present-moment experiences (i.e., thoughts and feelings) as they arise" (Baer, 2014) and "an attitude of openness, acceptance, and curiosity toward whatever arises" (Baer, 2014). Mindfulness requires dedicated practice both to achieve and to use to reduce negative stress effects. A variety of mindfulness approaches have been proposed and tested. Those with the best empirical support are mindfulness-based stress reduction, dialectical behavior therapy, and acceptance and commitment therapy (Baer, 2014). Mindfulness interventions can be combined with other efficacious treatments or can serve as primary interventions for stress management. Mindfulness as both a state and an intervention is not simple although it may appear so at first. Therefore nurses are urged to obtain specialized training in mindfulness approaches so they can use them in their practice. Mindfulness interventions have shown promise to improve quality of life in coping with various health conditions. For example, Lengacher and colleagues (2015) demonstrated the cost-effectiveness and efficacy of a mindfulness stress-reduction program in improving quality of life for breast cancer survivors.

The neuroscience basis of mindfulness remains a fruitful field of investigation. As is common to new areas of research, the studies to date generally lack robust methods and offer only speculative conclusions (Tang et al., 2015). Nonetheless, there is developing evidence that mindfulness meditation may precipitate neuroplastic changes "in the structure, and function of brain regions involved in regulation of attention, emotion and self-awareness" (Tang et al., 2015). The horizons are vast and exciting for future nurse scientists to engage in team science to explore the underpinnings of interventions

such as mindfulness.

Techniques for Developing Self-Awareness

Monitoring stress warning signs.

The negative stress cycle can be difficult to interrupt. Recognizing warning signs of stress is a necessary first step. Often individuals have long ignored physical, emotional, or behavioral cues or reactions to a stressor that are **stress warning signs.** A man who has chronic, intermittent backaches and ignores the daily muscle tension caused by poor posture that precedes the backaches provides an example. If he had attended to his early stress warning signs of poor posture and muscle tension, he might have avoided the backache that kept him from exercising and socializing. Becoming aware of these stress warning signs is the first step. Attending to these cues is the next step. After this connection has been made, the development of skills to reduce negative mood states, unhealthy behaviors, and physical symptoms becomes much easier. Furthermore, some people misinterpret physiological signs of anxiety (e.g., shortness of breath, racing heartbeat) as indicative of serious physical danger (e.g., suffocation, myocardial infarction). This tendency to misinterpret physical anxiety cues is referred to as **anxiety sensitivity**, a belief that body sensations associated with anxiety indicate imminent and dangerous outcomes, and is associated with various anxiety disorders and health anxiety. In a study of gender differences in anxiety sensitivity, Thompson and colleagues (2011) found that distraction worked better than sensation focusing in reducing stress for males. By assisting individuals who are prone to anxiety sensitivity to interpret body sensations accurately or to distract from the sensation, nurses can help reduce individuals' misinterpretations, as well as the likelihood of escalation of anxiety symptoms and possibly even development of anxiety disorders.

Nurses teach people to identify their warning signals of stress and to stop, take a few breaths, and break the cycle. Figure 13-3 shows a sample form for identifying and recording this information. These

signals or cues differ among individuals and can be physical, emotional, behavioral, cognitive, relational, or spiritual. When asked to monitor their responses to a particular event, individuals become more consciously aware of these cues. Although this heightened awareness initially may increase an individual's consciousness of physical pain or emotional discomfort, awareness is a necessary first step in recognizing the negative effects of stress and the relationship of thoughts, feelings, behavior, and biological processes. In addition, nurses and other clinicians have a responsibility to screen individuals for emotional distress to help them recognize and monitor their own physical and mood states. For individuals with health conditions such as coronary artery disease, which is known to have high comorbidity with emotional distress and specifically depression, routine screening should be the standard of care (Menezes et al., 2011).

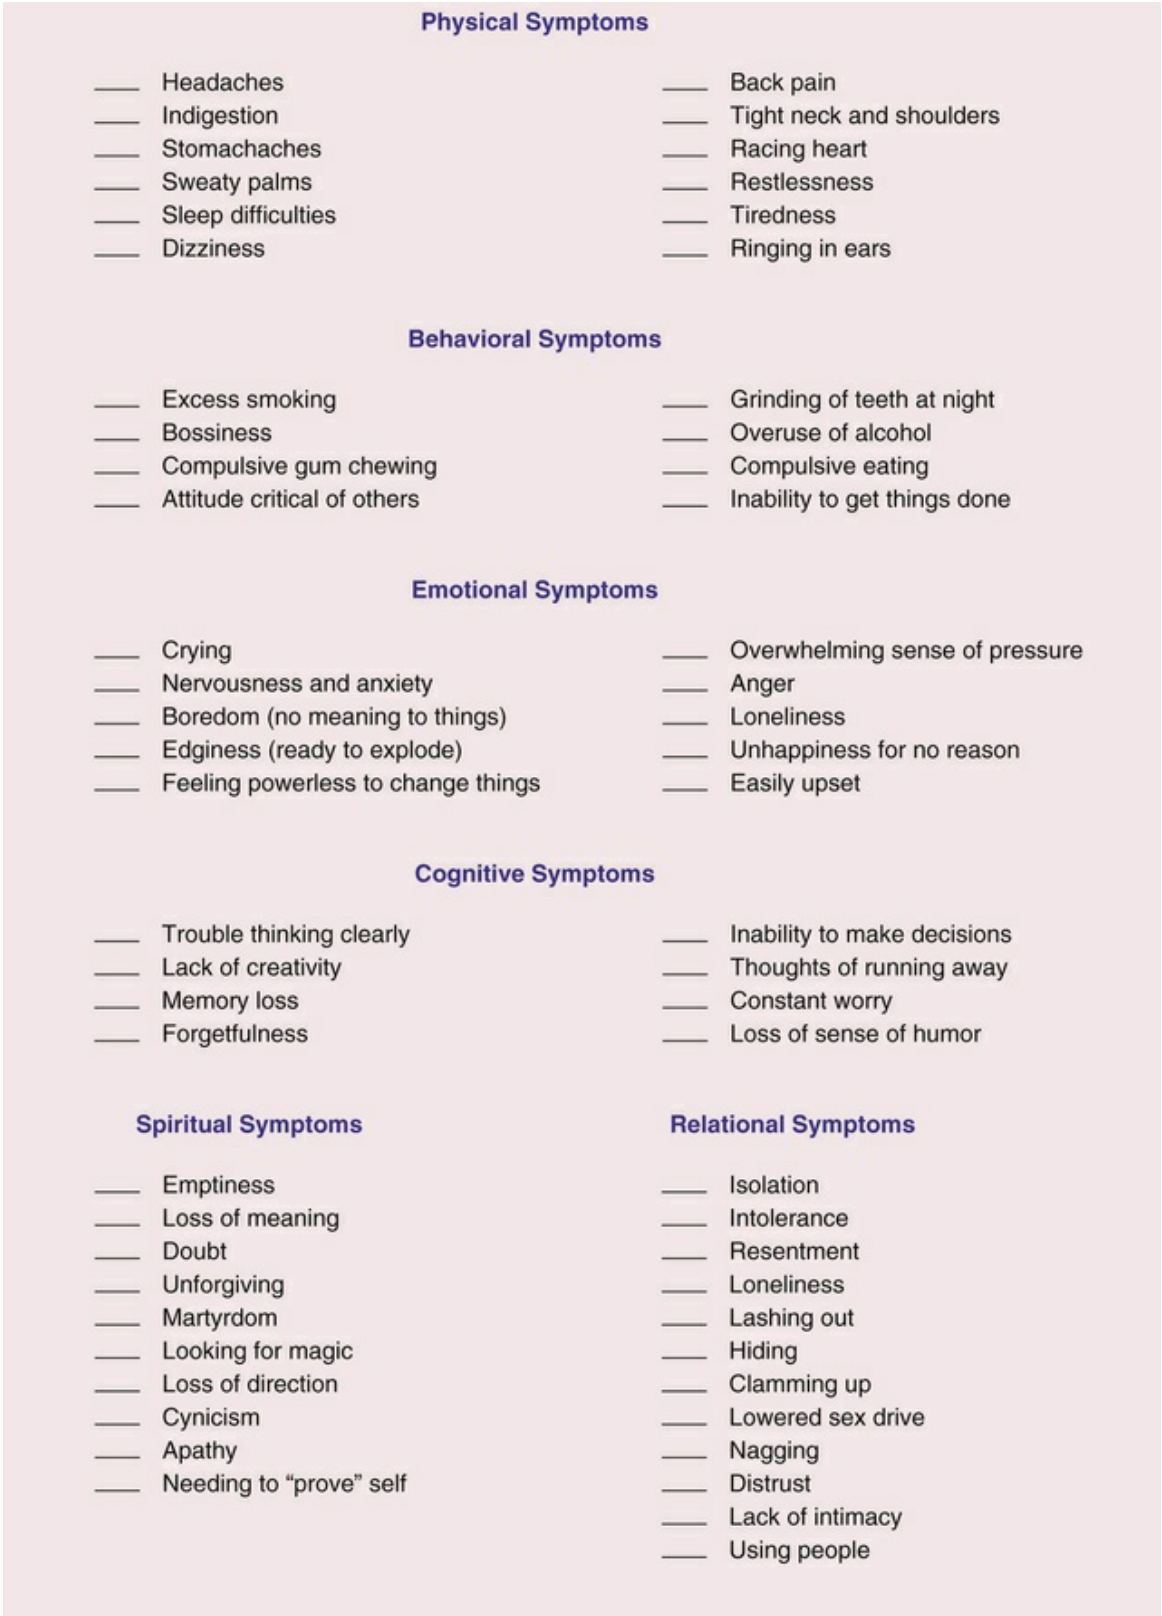

FIGURE 13-3 Stress warning signals. (From Medical symptom

reduction clinic patient notebook. [n.d.]. Boston: The Benson-Henry Institute for Mind Body Medicine of Massachusetts General Hospital, Harvard Medical School.)

Try this: Ask an individual to identify a stressful experience and the physical or emotional reactions (stress warning signals) to that particular experience. For example, after being instructed to stop, take a breath, and notice the physical and emotional response to a stressful situation, one woman related the following:

On my way to work yesterday, I sat in a huge traffic jam. I noticed that my heart was racing, my breathing had changed, and my hands were gripping the steering wheel. I felt angry and frustrated because I was going to be late for work.

Although these responses seem quite obvious, most people are unaware of the effects of stress on their minds and bodies. In the preceding example, the building of the woman's stress may continue to escalate at work, influencing her interactions with coworkers. Once individuals become aware of these effects, they may be able to release tension more easily, countering the negative effects of stress and increasing a sense of control. Techniques that help to reduce negative effects of stress include use of distraction by purposefully shifting focus to pleasant thoughts or engaging in a diversion activity, and use of a **relaxation response** technique, as described in the following section.

Learning and practicing a relaxation response technique.

Eliciting the relaxation response is another technique to help people develop awareness and counter the negative effects of stress. Relaxation response techniques oppose the stress response by reducing sympathetic arousal (Benson, 1975). The immediate physiological effects of relaxation are decreases in heart rate, blood pressure, respiration rate, and muscle tension. The long-term physiological effect is a decrease in central nervous system arousal with a concomitant decrease in musculoskeletal system, autonomic

nervous system, and psychoneuroendocrine system arousal. To the extent that stress causes or exacerbates a symptom, elicitation of the relaxation response can break this stress-symptom cycle. In addition to these physiological changes, psychological changes such as improved mood and behavioral changes, including a reduction in risky behaviors, can occur. The relaxation response can counteract stress-related disease processes, particularly processes associated with immunological, cardiovascular, and neurodegenerative disorders (Walsh, 2011).

The relaxation response is an innate physiological response (Benson, 1975); therefore a number of techniques that involve mental focusing can be used. Details on these techniques and guidelines for clinical applications can be found in Chapter 14. All of these techniques have two basic components:

- The repetition of a word, sound, phrase, prayer, image, or physical activity
- The passive disregard of everyday thoughts when they occur

Electronic recordings (e.g., DVDs, CDs, MP3/MP4 files, and mobile apps/downloads) can be used to help guide this process of focusing, especially during the initial learning phase.

Nurses can often introduce individuals to the immediate calming effects of the relaxation response in less than 5 minutes. One effective way is to have the person make a fist and notice what happens to the breathing pattern. Most people have a tendency to hold their breath while tensing a body part. Now ask the person to take a few deep diaphragmatic breaths while making a fist. Most people will notice that the tension is much harder to maintain while taking a deep breath. This awareness helps to recognize the relationship between breath and tension. Lamaze techniques for helping women manage pain during labor and delivery are based on this connection between breathing and relaxation. Most people hold their breath when they perceive a threat (stress), feel anxious, or become angry. By stopping and taking a few deep breaths when they become aware of physical changes (holding the breath or clenching the jaw) or emotional changes (feeling anxious or angry), individuals can elicit the

relaxation response, reduce sympathetic arousal, calm negative mood states, and gain a sense of control. **Yoga** and deep breathing can assist with **mindfulness** (i.e., awareness of perception) and promote relaxation.

Using mini relaxations.

Mini relaxations can be taught quickly and used throughout the day to help develop awareness and to counter the negative effects of stress on the mind, body, and spirit. Individuals can be taught to monitor minor stress warning signs (jaw and shoulder tension) and to use a mini-relaxation exercise to keep these initial symptoms of stress from developing into an incapacitating tension headache. A mini-relaxation exercise can be anything from a few conscious, deep diaphragmatic breaths to several minutes of sitting quietly (Box 13-4: Quality and Safety Scenario). Practice is needed to elicit the response quickly when stress, pain, or tension is recognized. The power of using relaxation, including visualization, and breathing techniques is illustrated by the personal experience of a nurse who had coached pregnant women and partners in Lamaze preparation for childbirth for 10 years before having her third baby. During pitocin induction due to a postdate determination, the woman was experiencing significant contractions. Her very experienced labor nurse commented that she was an advertisement for childbirth preparation. The woman managed a smile in response. The woman reflected:

Box 13-4

Quality and Safety Scenario

A Stress-Management Strategy for Nurses

Develop the skill of personal presence. Presence is the gift of self through availability and attention to needs. Presence means "being there" for another person. To be available to others in this way, first practice the skill of being present with yourself. One effective way of developing this skill is through mindfulness, which is the ability to

focus attention on what you are experiencing from moment to moment. Mindfulness encompasses the abilities of slowing down and bringing your full attention (thoughts, feelings, and body sensations) to the action in which you are engaged at the moment. The practice can be particularly useful in allowing yourself to extend the benefits of eliciting the relaxation response in more areas of your daily life.

The following are some ideas for practicing personal presence (mindfulness):

- When you awaken each morning, bring your full attention to your breathing. Allow your awareness to expand gradually into the room and then slowly begin to listen to the sounds of the outdoors.

- On your way to work, focus on how you walk, drive, or ride the transit. Take some deep diaphragmatic breaths and relax your body as you travel.

- Take a moment to attend to your breath, relax your body, and focus your mind before entering a care recipient's room.

- As you eat a meal, carefully examine it through all of your senses—the sight, smell, touch, taste, and the sound of each bite. Mindfully enjoy this new experience.

- Recurring events of the day can become cues for a mini relaxation (the ringing telephone; auscultating a heartbeat; answering a call light, before, during, and after rounds or report).

- Make the transition home from work mindful. Leave thoughts and worries of work at work and be conscious of your home environment each day.

Once again, focus on your breathing and become completely aware of your surroundings as you go to sleep. Practice mindfully letting go of today and tomorrow as you allow your mind and body to get some much-needed rest.

Modified from Benson-Henry Institute for Mind Body Medicine of Massachusetts General Hospital. (n.d.). *Stress.* https://www.bensonhenryinstitute.org/

The contractions were tough. I think that the pitocin escalated the process so that contractions increased quickly from mild to intense. Did my Lamaze relaxation techniques help? Oh yes. Was it still painful —Oh yes. However, I was able to make it through this and two previous labors and deliveries without an epidural by using relaxation techniques that I had taught and practiced. I cannot emphasize enough that relaxation techniques including breathing, visualization, distraction, and partner/nurse coaching support are powerful tools. These techniques require practice to be called upon in an instant of pain or stress. Medication and/or anesthesia remain as helpful tools in situations of acute pain such as labor, surgery, injury, or ongoing stress, but the power of our capacities to harness our own abilities are powerful and should not be overlooked. Let's empower ourselves so that pharmacotherapeutics is not the immediate go-to solution for stress and pain!

Alternative and complementary therapies.

A variety of alternative and complementary therapies can prevent and reduce harmful effects of stress (Snyder & Lindquist, 2010). These therapies include **acupuncture**, **hypnosis**, **aromatherapy**, **reflexology**, **reiki**, and chiropractic and herbal therapies. These approaches have developed outside the mainstream of traditional Western medicine; however, developing evidence of efficacy has promoted growing acceptance of some of these approaches. People are increasingly using alternative and complementary practices as self-help measures, and research to study their effects has exploded in recent years. Nurses can help individuals evaluate the safety and efficacy of various alternative and complementary therapies. In particular, herbal remedies require cautious use because they can have harmful, as well as beneficial, effects, and they sometimes interfere with other treatments and medications. Among the alternative therapies available, there is strong evidence of effectiveness of acupuncture and

hypnosis, and they are becoming widely accepted within mainstream health care.

Acupuncture is an ancient Chinese technique used to reduce pain and to prevent and manage various disorders by placement of fine needles at specific **meridian** points on the body. Acupuncture is not a self-help approach, so seeking treatment from an experienced acupuncturist is required. The Western scientific community cannot explain why acupuncture works but acknowledges its effectiveness. Even the World Health Organization has listed illnesses that can be managed with acupuncture (Stuart, 2013), and some health insurance plans provide reimbursement for acupuncture treatments.

Hypnosis comes from a Greek word meaning sleep. Hypnosis narrows consciousness and elicits relaxation, inertia, and passivity, like sleep, yet awareness is never lost completely and the hypnotized person can respond (Brann et al., 2011). The exact mechanisms through which hypnosis works are not known, although perhaps its ability to induce deep relaxation and its possible action in shifting brain activity from the "analytical" left side to the "nonanalytical" right side might be explanatory. Nevertheless, its effectiveness in managing a variety of conditions, notably smoking and anxiety-related problems, and managing pain is well recognized. Trained therapists provide hypnotherapy to manage stress and various mental health problems, including phobias, addictions, and posttraumatic stress disorder. Self-hypnosis, a form of deep relaxation similar to the relaxation techniques described in this chapter, can be a useful stress-reduction tool. Self-help guides provide safe and easy-to-follow guidelines. One note of caution is warranted: hypnosis is not recommended for people with organic brain disorders, psychotic disorders, or other severe mental disorders. For individuals with trauma histories, practice with an expert clinician is recommended.

Reiki (pronounced ray-kee) is made up of two Japanese words: *rei*, or universal spirit (sometimes thought of as a supreme being), and *ki*. Thus the word reiki means universal life energy. Reiki is a therapy that uses energy fields with the intent to affect health. To transmit ki, believed to be a life-force energy, the reiki practitioner places hands

on or near the person receiving treatment. In the United States, reiki is designated as a form of complementary and alternative medicine (National Center for Complementary and Alternative Medicine, n.d.; Snyder & Lindquist, 2010).

Expressive writing.

Transforming thoughts and emotions related to stressful experiences into written language has demonstrated positive effects on health (North et al., 2011). In its therapeutic meaning, **expressive writing** involves telling a "story" about traumatic, emotionally charged, or stressful events and personal reactions. **Journal writing**—more specifically, self-confessional writing—is a form of expressive writing that is typically done via entries in a journal over time that describe unfolding personal responses to life events. Expressive writing is useful in disclosing and processing emotions, and in measurably improving physical and mental health.

Expressive writing, including journaling, can help people reflect on stressful events and their reactions to these events. Such reflection is an opportunity to reform perceptions and to consider alternative ways to manage stress. Individuals may find resolutions to conflicts that work uniquely for them. These resolutions may then increase a sense of control and mediate negative consequences of stress. This self-reflective process shares elements of CBT—an intervention effective in reducing harmful effects of stress. (See Chapter 4, Figure 4-4.)

Nurses can advise people to get a special notebook or a journal (or use an electronic tablet or computer) and write about a stressful event for 15 minutes a day in a setting in which they will not be interrupted. From a health perspective, people will be more effective when they make themselves the only audience. The nurse should warn the individual that he or she may feel sad or depressed immediately after the writing session, but these feelings usually dissipate within an hour. Nonetheless, exploring deep thoughts and feelings on paper is not a panacea. When an individual is coping with death, divorce, or some other major stressor, feeling better instantly after writing cannot be expected. A person can, however, develop a clearer understanding

of feelings and of the situation through journal writing. In other words, journal writing helps people objectify experiences, identify the influence of stress on symptoms, and develop insights into more effective problem-solving. Some individuals may recognize the need for psychotherapeutic support through journal writing, and an appropriate referral can then be made. Nurses can use the same approaches to examine their own stressful work-related situations to reflect, analyze their responses/reactions, and generate effective responses to similar experiences in the future.

Nutrition: Healthy Diet

Countering negative effects of stress requires caring for physical health and well-being. The mind and body are connected; therefore paying attention to one while ignoring the other does not promote overall health. The body requires rest, a healthy diet of balanced food choices, and exercise. In the last few decades, nutrition has moved to the forefront as a major component of health promotion, disease prevention, and symptom management. Food is now viewed as a positive influence on health, physical performance, and state of mind rather than simply a fuel needed to prevent disease and sustain life. Adaptive eating is characterized by balanced eating patterns and calorie intake as well as appropriate body weight for height. Nutrition is an important component of early intervention strategies to improve physical, cognitive, emotional, social, and spiritual functioning.

However, the American lifestyle has made practicing healthy eating habits increasingly difficult. Americans frequently replace nutritionally balanced meals with readily available high-fat, high-calorie food (US Department of Agriculture, 2012). One of the frustrations that nurses experience is trying to help children and adults develop healthy eating habits. This effort requires planning and correctly choosing a variety of foods and eating a diet low in fat, saturated fat, and cholesterol, with plenty of vegetables, fruits, and grain products. The current US dietary guidelines (US Department of Agriculture, 2012) are based on the following two overarching concepts: focus on calorie balance over time to achieve and maintain a

healthy weight; focus on consuming nutrient-dense foods and beverages. Daily food choices should be made from the five food groups. Key recommendations also highlight the importance of calorie control and physical activity. Guidelines continue to undergo evaluation and revision; for example, guidelines about "healthy foods" are under ongoing review, so nurses are urged to check for updated guidelines. A detailed discussion of the health benefits of balanced nutrition and guidelines throughout the life span can be found in Chapter 11.

Encouraging healthier dietary choices helps people to recognize that control over their health and well-being is possible. This knowledge, in turn, helps counter the negative effects of stress and lower the stress-disinhibition effect that can influence poor dietary choices. Nurses encourage people to monitor their daily dietary patterns to gain awareness of how they use food in times of stress. Tools such as food diaries (24-hour recall) help people to monitor the amount and quality of what they eat and drink and to set realistic goals. An example of an on-line free program is MyFitnessPal (2015), which combines nutrition tips and a way to monitor exercise in a journal format.

Physical Activity

Combining a healthy diet with a regular exercise routine has many health benefits and can positively affect quality of life. For example, one of the most effective ways to lose weight and improve self-esteem is to combine exercise with nutritious eating. Exercise (physical activity that increases strength and flexibility and improves conditioning) and balanced nutrition serve as protective factors against several major chronic diseases. Regular physical activity decreases the risk of death from heart disease, lowers the risk of developing **diabetes**, and is associated with a decreased risk of colon cancer (USDHHS, 2011). Exercise helps prevent high blood pressure and helps lower blood pressure in people with elevated levels. Regular physical activity, even at moderate levels, is associated with lower death rates for adults of any age. Psychological well-being is

enhanced, and the risk of developing depression can be reduced; regular physical activity appears to reduce symptoms of depression and anxiety and to improve mood.

Additionally, children and adolescents need weight-bearing exercise for normal skeletal development, and young adults need this type of exercise to achieve and maintain peak bone mass (USDHHS, 2011). Regular physical activity also increases the ability of older people, and those with certain chronic, disabling conditions, to perform activities of daily living. Nevertheless, high stress could increase injury risk for athletes, and injured athletes may experience greater stress than noninjured peers when they are sidelined from competition. Chapter 12 provides a comprehensive discussion of the benefits of exercise and its clinical application throughout the life span.

Regular physical activity helps people adopt a more active lifestyle as they begin to feel better physically and emotionally, thereby breaking the negative stress cycle (Figure 13-4). Positive effects can be obtained with exercise of only moderate intensity. For example, a brisk walk of 30 to 60 minutes, 3 to 5 times a week, promotes fitness and decreases the risk of disease. Being physically active on a daily basis is extremely important; therefore nurses can help individuals increase their physical activity by suggesting a variety of activities in which they might engage each day (Box 13-5). An exercise diary can generate a baseline for usual activity to set realistic goals and monitor progress. By simply changing a few daily routines, individuals can gain enormous physical, psychosocial, and spiritual rewards that promote health and break the negative stress cycle.

FIGURE 13-4 Regular physical activity helps individuals adopt a more active lifestyle.

Box 13-5

Helping Individuals Increase Physical Activity

Nurses can suggest ways for individuals to increase physical activity throughout the day, including:

- Have fun and play active games with children.
- Engage in a sport.
- Find a friend with whom to walk or jog.
- Take a class in yoga or tai chi.
- Get and walk a dog.
- Garden on the weekends.
- Walk or bicycle to school or work.
- Take the stairs, never the elevator.

- Park the car at the farthest point in the parking lot at work, at school, or when shopping.

By simply changing a few daily routines, a person can gain enormous physical, psychosocial, and spiritual rewards that promote health and break the negative stress cycle.

Sleep Hygiene

Health and the ability to meet life's many demands and manage stress effectively require proper rest. Many people experience sleep deprivation and sleep disorders (e.g., sleep apnea) that can cause or exacerbate conditions such as depression and fatigue and contribute to poor concentration and ineffective problem-solving. Insomnia can be induced by stress or other cognitive-behavioral factors, such as unrealistic expectations, inappropriate scheduling of sleep, trying too hard to sleep, consuming caffeine, getting inadequate exercise, and a number of other factors, including illness, alcohol use, or drug use (Stuart, 2013). Determining the extent to which sleep disturbance is the result of behavior or stress-related issues is a necessary assessment. Overcoming sleep disturbances cannot be done quickly. Changing these behaviors requires patience and persistence. Once the factors associated with sleep disturbance have been identified, nurses can help individuals improve their sleep patterns by counseling them to follow several **sleep hygiene** or behavior guidelines (keeping a sleep diary, having a regular sleep-wake cycle, and making prudent dietary changes). Referral for appropriate evaluation of possible disorders such as sleep apnea is also a necessary nursing intervention. Assisting people to make healthy behavior changes in their sleep habits provides another opportunity for people to increase self-regulation, confidence, and control, thereby reducing stress and improving quality of life. Box 13-6 presents several sleep hygiene strategies.

Box 13-6

Sleep Hygiene Strategies

Nurses find the following suggestions to be helpful for individuals with sleep disturbance resulting from behavioral or stress-related issues:

- Keep a sleep diary, which helps determine sleep patterns more accurately, assess progress, and reinforce behavior change.
- Challenge irrational beliefs.
- Reduce consumption of alcohol and caffeine. (Chapter 11 gives some tips.)
- Avoid use of sleeping pills.
- Have a regular sleep-wake schedule, even on the weekends.
- If you are unable to fall asleep within 20 to 30 minutes, or if you wake up and are unable to fall back to sleep within that time, get out of bed and do something until you are groggy and sleepy again.
- Focus on relaxation, not sleep. Use a relaxation tape, and practice diaphragmatic breathing. Limit naps during the day to less than 45 minutes. Longer naps reset the biological clock and disturb nighttime sleep.
- Exercise within 3 to 6 hours of bedtime. Exercise improves sleep by producing a significant rise in body temperature, followed by a compensatory drop a few hours later, making it easier to fall asleep and stay asleep. Furthermore, because exercise is a physical stressor, the brain compensates for this by increasing the amount of deep sleep.
- Take a hot bath 2 hours before bedtime. The temperature drop after the bath helps to induce sleep.
- Sleep in a cool room. Individuals become sleepier and less active

when body temperature falls.

Cognitive-Behavioral Restructuring

Many stressful situations can be created or exacerbated by negative, exaggerated, catastrophic thinking. CBT is a conceptually based short-term intervention to modify this thinking and related behaviors, and thereby reduce stress. In the context of therapy, cognitive-behavioral restructuring is a technique or a series of strategies that help people evaluate their thoughts, challenge them, and replace them with more rational cognitive and behavioral responses (Beck, 1976, 1979; Clark & Beck, 2012; Dowd et al., 2015). Although advanced training is needed to provide CBT and nurses are encouraged to do so, nurses can safely and effectively use basic strategies. A helpful resource for nurses is the Beck Institute for Cognitive Behavior Therapy (2012).

Appraisal, or the way in which a situation is viewed, can be a major cause of stress, making CBT especially suited for stress management. When situations are viewed in a negative, distorted, or illogical manner, such perceptions can adversely affect emotions, behaviors, beliefs, and physiological parameters. Cognitive-behavioral restructuring teaches people to recognize that negative thinking often causes emotional distress and associated behaviors. This recognition, in turn, alters problematic thinking and behavior, reduces the negative consequences of stress, and enhances health (Stuart, 2013).

Cognitive-behavioral restructuring does not gloss over or deny misfortune, suffering, or negative feelings. Many circumstances exist in peoples' lives for which it is appropriate to feel sad, anxious, angry, or depressed. More accurately, cognitive-behavioral restructuring is a technique that helps some people become unstuck from these moods so that they can experience a broader range of feelings and try out new behaviors (Stuart, 2013). In this structured method, individuals are asked to consider their cognitive appraisal of a situation and how this assessment affects feelings, behaviors, and physiological

processes. Reframing, or cognitive reappraisal, educates individuals in monitoring thoughts and replacing those that are negative and irrational with those that are more realistic and helpful. Adding behaviors that are consistent with reframed thinking follows.

For example, a woman may have had plans to meet a friend for lunch on a day she woke up with a migraine headache. She might begin to think such thoughts as "This always happens to me when I have plans," "This headache will never go away," "I shouldn't have to deal with this," or "My day is ruined." The result of this negative, irrational self-talk is disappointment, frustration, and anger. This emotional arousal will, in turn, increase muscle tension and a variety of other stress-related symptoms, which may exacerbate the headache. To help individuals develop the skill of cognitive-behavioral restructuring, nurses can teach them to examine a stressful situation using the four-step innovative practice CBT approach highlighted in Box 13-7: Innovative Practice.

Box 13-7

Innovative Practice

The Four Step Approach to Cognitive Restructuring Enhanced With Technology

To help individuals develop the skill of cognitive restructuring, nurses can teach them to examine a stressful situation using the following four-step approach:

- *Stop* (break the cycle of escalating, negative thoughts).
- *Breathe deeply* (elicit the relaxation response and release tension).
- *Reflect* (ask "What is going on here? What am I thinking? Is the thought true? Is the thought helpful? Am I jumping to conclusions or magnifying the situation?").

- *Choose* a more realistic, rational response. Try out the alternative response in a future situation.

Alternative Approach

Teaching/coaching can be done face-to-face or can be provided via technology (e.g., a website and/or smartphone application that shows the previous steps with a feedback interface). Via technology, feedback can be given via text or e-mail messages to correct negative thoughts and to provide suggestions and positive reinforcement for steps 2 to 4 when success is reported. Phone and/or face-to-face interaction can augment contact via technology when possible. Tracking successful cognitive restructuring via on-line entry can provide useful outcome data. As Internet and smartphone penetration increase and costs decrease, use of such technological interventions will increasingly be cost-effective ways to reach more individuals and can be applied across a range of technological platforms (e.g., computers, smartphones, and tablets). Reminder generic affirmations also can be added via text messaging at very low cost to encourage practice of the steps.

Modified from Clark, D. A., & Beck, A. T. (2012). *The anxiety and worry workbook: The cognitive behavioral solution.* New York: Guilford Press; Stuart, G. W. (2009). Psychophysiological responses and somatoform and sleep disorders. In G. W. Stuart & M. T. Laraia (Eds.), *Principles and practice of psychiatric nursing* (9th ed., p. 241). St Louis: Mosby; Stuart, G. W. (Ed.) (2013). *Principles and practice of psychiatric nursing* (10th ed.). St. Louis: Mosby.

In the previous example, the woman may reflect that "I am having a migraine headache, and I hate that it is on a day that I had made plans, but I will take my medication, listen to my relaxation tapes, and rest. I'll call my friend and see if we can change our plans. Perhaps she can come over to visit me for tea this afternoon if I feel better." Although it is understandable that anyone would be disappointed and upset over this situation, application of the four-step cognitive restructuring technique can help individuals identify healthy choices and gain a sense of control.

Based on the work of pioneers such as Aaron Beck (1976, 1979) and

Albert Ellis (Ellis, 1962; Ellis & Dryden, 1987), cognitive therapy has emerged during the past several decades as a treatment designed to alter dysfunctional beliefs and thoughts associated with depression, anxiety disorders, and other emotional problems (Clark & Beck, 2012). Over time, theorists, clinical researchers, and clinicians recognized the effectiveness of this approach for many people, as well as the value of linking helpful alterations in thinking to complementary behavioral changes. As a result, CBT emerged. CBT is an efficacious treatment approach for many stress-related and mental health disorders. For example, researchers have shown that CBT is effective, alone or with other therapies or medication, in alleviating postpartum depression (Bobo & Yawn, 2014). Evidence provides strong support for use of cognitive-behavioral restructuring as a stress-management approach. A comparison of an on-line mindfulness-based cognitive therapy intervention (Mindfulness in Action) with on-line pain management psychoeducation showed positive outcomes in self well-being from both approaches, yet Mindfulness in Action was associated with more pronounced positive outcomes (Dowd et al., 2015). Although the results were promising, more research is needed to demonstrate efficacy. Sensitivity to stress appraisals is also situated within a person's culture and experience. Cultural sensitivity to such influences is critical to providing quality care. Box 13-8: Diversity Awareness presents relevant information related to the effects of racial/ethnic discrimination on cognitive appraisals of interactions as threatening and harmful, resulting in increased overall stress burden.

Box 13-8

Diversity Awareness

Social Stressors Can Lead to Discrimination for Vulnerable Populations

Health is perceived through one's spiritual beliefs, holistic practice, and biomedical perspectives. Nurses understand cultural sensitivity

when providing care and the importance of clear communication in multicultural care. Greater concern for health literacy and improved coordination with support organizations are needed. Barriers such as discrimination and geopolitical tension may affect the ability to cope through frustration and may influence health care outcomes. *Healthy People 2020* identifies the need to close the gap and supports health equity by addressing chronic disease and infant mortality rates. For example, social stressors have been linked to increased depressive symptoms among antepartum black American women (Dailey et al., 2011). Thus in addition to the need for universal symptom screening, it is essential that nurses develop and test interventions to ameliorate effects of social stressors such as discrimination for vulnerable populations.

From Dailey, D. E., Dawn, E., & Humphreys, J. C. (2011). Social stressors associated with antepartum depressive symptoms in low-income African American women. *Public Health Nursing*, *28*, 203–212.

Affirmations

Affirmations can be an effective stress-management and cognitive-behavioral restructuring skill because they are a method of countering self-defeating negative thoughts and attitudes in addition to being helpful in addressing spiritual needs. An affirmation is a positive thought, in the form of a short phrase or saying, which has meaning for the individual. By reinforcing new ways of thinking or behaving in the present moment, affirmations are statements that people can use to reaffirm new intentions and to clarify goals.

Nurses coach individuals to create an affirmation as a way of developing a more helpful, realistic belief system. For example, thoughts such as “I can't handle this” and “My day is ruined” can be countered with “I can handle this” and “I know ways to increase my comfort.” Repeating an affirmation often throughout the day, perhaps after elicitation of the relaxation response or as part of a breathing exercise, can become second nature and can help to enhance self-esteem and reduce stress.

Social Support

Having supportive family, friends, and coworkers is for many individuals an important contributor to effective coping and stress hardiness (Kobasa et al., 1982). Many people believe that confiding in others and talking out problems can be a helpful way to get good advice or uncritical support. Social support comprises a network of close family, friends, coworkers, and professionals. The social support literature notes that both the number of supports and the quality of the relationships are important (van Woerden et al., 2011).

Research outcomes demonstrate the protective health effects of social support. However, influences may differ by type or source of support. For example, van Woerden and colleagues (2011) examined the effects of social support from personal, professional, and community networks and other factors in relation to self-rated health using a cross-sectional postal and Web-based survey with a random sample of 10,000 households in Wandsworth, London. The results demonstrated that social support from family or friends, at work, and by civic participation was associated with a lower likelihood of poor self-rated health, but that social support from neighbors was associated with a higher likelihood of reporting poor health. The outcomes suggest that most of the health effects of social support are complementary. Nonetheless, the finding that the health effects of family social support were insignificant after the other social support variables had been controlled for suggests that it can be compensated by support from other sources. Sociodemographic variables (e.g., sex, age, being married, being employed, and owning a home) were also associated with better self-rated health. The principal message is that a variety of sources of social support may promote health and that nurses should ask individuals about all types of social support so as to help them cultivate and use support from many sources. In addition, substituting support from a different source when it is lacking from one usual source such as the family can be a helpful strategy.

Nursing interventions are aimed at facilitating social support to promote effective coping and reduce stress. Using information available in their local communities or through national organizations,

nurses suggest support groups (see Chapter 8), website chat rooms, social networking sites, educational classes, and exercise facilities. Individuals and their families are often referred to volunteer organizations such as the American Lung Association, the American Heart Association, the American Cancer Society, and the Arthritis Foundation for resources related to specific health-promotion/maintenance needs that also may provide social support opportunities.

Assertive Communication

Effective communication is an important stress-management skill. An important coping and problem-solving skill, communication can be adversely affected by exaggerated negative thoughts and deeply held negative beliefs and assumptions (Stuart, 2013). (See Chapter 4 for additional discussion of communication.) People who have difficulty with communication usually have one or all of the following problems:

- Disparity between what they say (statement) and what they want (intent)
- Confusion about or resistance to stating clearly how they feel, what they want, or what they need (lack of assertiveness), with either a tendency to deny their own feelings (passiveness) or indifference toward the feelings of others (aggressiveness)
- Difficulty listening to others

The importance of matching the statement with intention is illustrated by the following example:

As Timothy is leaving for his basketball game on a Saturday afternoon, his mother tells him, "Remember to be home early tonight." When Timothy arrives home at 9 : 00 pm, his mother, who is waiting at the front door, yells, "Where were you? Is this your idea of early? You know your father and I had plans tonight. We were counting on you. You think only of yourself. This always happens. You'll never change.

You'll always be irresponsible and selfish."

The first guideline for effective communication is that people need to be clear about what they want and what they need (intent) in statements to others. Although it would be wonderful if a son or daughter, spouse, friend, or others were great mind readers, assuming that people automatically know what is meant does little to help with communication. Nurses help individuals match statements with intentions. This process requires that individuals recognize distorted, exaggerated thoughts and emotions and take responsibility for their part of the conversation. Communicating effectively is a learned art and skill.

In our reviewing the previous example, it is helpful to note that if the mother's intention was to have her son home before 8 : 00 p.m., then her statement needed to indicate this. She could have said "I hope you enjoy the game, but remember your father and I are going out tonight. We need to have you home before 8 : 00 p.m. to take care of your sister." It is important that the person understands that the other person in the conversation is not obligated to respond as one would wish. However, a request can be much clearer when the statement reflects the intent.

The next guideline for effective communication is to be assertive. **Assertive communication**, in most cases, is the most effective way to communicate. An assertive statement is nonjudgmental, expresses feelings and opinions, and reaffirms perceived rights. The general format of an assertive statement is: *I feel* [emotion], *when you* [the behavior], *because* [explanation].

The formula requires that all three elements be included. **Cognitive restructuring**, as described earlier, facilitates assertive communication because it requires individuals to identify their thoughts and feelings. In the previous example, Timothy's mother could:

- *Stop* (breaking the cycle of escalating, negative thoughts)
- *Breathe deeply* (releasing physical tension; promoting relaxation)
- *Reflect:*

- How do I feel emotionally? (e.g., frustrated)

- What are my automatic thoughts? ("If he cared about us, then he would have been home on time. He's always selfish and irresponsible. He's never going to change.")

- *Choose:*

- A more realistic, helpful way of thinking ("He's not always selfish and irresponsible. Even though it feels like he doesn't care about us when he does this, I know he cares.")

Becoming aware of her automatic thoughts and feelings would help Timothy's mother plan an assertive statement when Timothy comes home. She could then say "I feel frustrated [emotion] when you are late [behavior] because I expected you would be home in time to care for your sister while your father and I went out, or that you would have called if you were going to be late [explanation]." This statement both makes her feelings clear and explains why she feels this way, which in turn provides a better opportunity to work on problem-solving. When people cannot verbalize both their feelings and their needs, others are forced to figure out what they are. When others fail to do so correctly, individuals may feel victimized and blame the others for not understanding. Nurses help people recognize that they have a right and a responsibility to speak up and to do so in an assertive manner. The nurse helps individuals in matching their emotions with the explanation (frustration equals unmet expectation). It is important to remind them that this way of communicating may feel awkward and uncomfortable at first. Practicing this technique many times will be required before communication improves. Role

play can be a useful technique to practice. Other people need time to become accustomed to the changes. Effective communication takes both practice and patience with everyone involved.

Empathy

Empathy is an effective stress-management intervention because it assists with communication. Empathy is the ability to consider another person's perspective and to communicate this understanding back to that person. Empathy guides individuals to become better listeners.

Empathy can be facilitated through the technique of active listening. **Active listening** requires conscious, empathic, nonjudgmental awareness. Listening also helps clarify the issues involved and can deescalate many emotional exchanges. The use of focus groups can assist the nurse in understanding concerns, such as a parent group concerned about nutrition choices in the lunch room. For example, during a situation in which a parent announces "I'm fed up with the food selection in the cafeteria," the response may be important to resolving the issues without promoting further miscommunications and increasing problems. Rather than being caught by a defensive, emotional reaction, individuals can learn to communicate empathetically using the four-step approach:

- *Stop* (breaking the cycle of escalating, negative thoughts)
- *Breathe deeply* (releasing physical tension; promoting relaxation)
- *Reflect*:

- How do I feel emotionally? (hurt, angry)
- What are my automatic thoughts? ("How could [person] say that? It's not my fault. I have things to do. [Person] always accuses me. This is never going to change.")

- What are the thoughts and emotions being expressed by the other person?

- *Choose*:

- "My feelings are hurt, but I don't have to react defensively."

- "I'm going to try to understand [person's] perspective using this phrase: 'You sound ____about____' and listen to [person's] response."

By using this phrase ('You sound ____about____'), an individual can gain awareness from another person's perspective (Rogers, 1951). If we continue with the scenario, the response might be "You sound upset about the choice of food available…." Possible responses to this empathetic statement might include "It's not just about that. Everything went wrong today, and this was just one more thing when my child complains about lunch" and "You're right. I hate having to pay for food that my child will not eat."

When one uses active listening, the other person often feels heard. An opportunity to clarify any misunderstanding becomes available. This exercise may help reduce emotional arousal, defensive behavior, and conflict. Active listening allows the individual to buy time and to get a better perspective on what the other person is thinking and feeling. Individuals can then make a choice as to how they want to respond. They may choose to use assertive communication or to step away from the interaction. Active listening promotes empathic, objective, and nonjudgmental communication. Nurses recommend use of stress-management skills that include active listening techniques to facilitate effective communication, which, in turn, reduces conflict and stress.

Healthy Pleasures

Engaging in **healthy pleasures** (activities that bring feelings of peace, joy, and happiness) is, for most individuals, an important part of life. However, for individuals who are feeling overwhelmed with daily hassles of work-life balance, illness, or loss, this practice may have been lost. Individuals may feel that they do not deserve to have pleasure or that they are waiting for happiness until they feel better, until the stressors are resolved, or until they go away. This belief makes breaking the stress cycle even more challenging; however, rewards motivate behavior (Stuart, 2013). By nurses asking people to pursue a healthy and pleasurable activity every week, motivating them to become more involved in their lives and break this cycle is often easier. The activity can be simple, and it need not cost money. For example, people often find pleasure in enjoying nature, spending time with a friend, reading a book, or watching a movie. Hobbies are purposeful leisure-time activities that can balance hectic, stressful lives. A hobby should be chosen from interest and/or talent. Many hobbies have added benefits of increasing activity (e.g., gardening) or promoting social engagement (e.g., a book club or chorus). Nurses advise individuals to make leisure-time activities a regular part of the week as a purposeful and conscious plan to break the stress cycle.

Spiritual Practice

In response to stress, people can feel disconnected from life's meaning and purpose, which in turn affects spiritual health and well-being. Meeting spiritual needs may be facilitated by **spiritual practice** or activities that help people find meaning, purpose, and connection. For example, individuals may choose to elicit the relaxation response through prayer. This focused, relaxed state of mind might help them develop a spiritual perspective that can engender a shift in values and beliefs to help them cope with a stressor they cannot change, such as chronic illness or loss of a loved one. Expression of anger or confusion in the face of difficulties, trauma, or tragedy also can provide a therapeutic outlet, but conversely may engender spiritual or religious

doubt, or a sense of alienation from one's beliefs. Nurses suggest a referral to a chaplain or clergy member, provide spiritual music or art work, recommend spiritual reading material, and provide personal **presence** (see Box 13-4: Quality and Safety Scenario). Willis and colleagues (2015) explicated how spiritual healing manifested itself in the aftermath of childhood maltreatment and point out the potential helpfulness of "constructing caring-healing interventions aimed at both cultivating spiritual consciousness and facilitating loving-kindness and acts of letting go in the healing process."

Nurses propose activities that provide a sense of meaning and purpose. Keeping a journal can be an important strategy to help individuals focus on aspects of life that are more positive and that become clouded from view when a person is feeling overwhelmed by stress. Finding ways of helping others (e.g., tutoring children, reading to the blind, or visiting an older adult) can have a positive influence on spiritual health and well-being. Altruism, generosity, kindness, and service to others are more than moral virtues. These attributes not only help to make the world a better place but also help people find meaning and purpose in life. Religious and existential well-being has provided some defense against depression for people with chronic and life-threatening conditions. Older, chronically ill, and homebound people can be encouraged to produce written or oral histories that can be a legacy or, when able, to contact others needing care or to make telephone calls to raise funds for a favorite charity. In addition, nurses and other health care professionals can assist individuals and families to describe and clarify their personal religious and spiritual perspectives, especially in light of evolving practices/meaning structures and high rates of interfaith marriages/partnerships (Walsh, 2011). Spirituality and religious affiliation cannot be equated. Additionally, being part of a "faith community" may provide an important source of social support for many people. Within faith communities, nurses (also known as "parish" nurses) act as facilitators, educators, and referrers to individuals and families in promoting holistic care. Nurses can encourage individuals to search for a community that is comfortable, accepting, and supportive.

Clarifying Values and Beliefs

To manage stress and develop a balanced lifestyle, people must recognize the things and values that are important to them, reflect on where they are in life, evaluate what needs to be changed, and generate an action plan for that change (see Chapter 4). This process is known as **values clarification**. The first step is to identify what is important, meaningful, and valuable so as to assess whether actions are consistent with beliefs. What people believe and value guides their actions by endorsing certain behaviors and changing others. When people assess their values and beliefs, they use the ability to make their own choices rather than relying on beliefs and values dictated to them by others.

One method nurses use to help people identify what they value and, ultimately, to help them clarify the relationship between their beliefs and actions is to ask them to identify what is important or meaningful to them. The form in Figure 13-5 is an example of questions used in the Medical Symptom Reduction Program at the Benson-Henry Institute for Mind Body Medicine of Massachusetts General Hospital (n.d.) in Boston. Individuals are asked to identify what is important and meaningful to them in eight domains. Nurses change the domains to reflect more accurately the values and beliefs of the individuals they are counseling. After reviewing the results, individuals may find that they have not been doing certain things that are important to them (becoming more physically active, eating a healthier diet, volunteering, or spending time with their children). When people detect inconsistencies between their values and their actual living habits, they can begin to develop a working plan for correcting these inconsistencies. This process enables them to make conscious choices and to have more control (see Figure 13-5).

"What Is Important and Meaningful to You in Life?"

In each of the following areas, what do you want for yourself, today, next week, a year from now?

Under each of the following categories, please ask yourself these important questions.

Professional, educational, and intellectual
Today_____

FIGURE 13-5 What is important and meaningful to you in life? (From Medical symptom reduction program patient notebook. [n.d.]. Boston: The Benson-Henry Institute for Mind Body Medicine of Massachusetts

General Hospital, Harvard Medical School.)

Setting Realistic Goals

Developing an action plan for change to work toward a more balanced health-promoting lifestyle that is consistent with a person's values and beliefs is an important stress-management strategy. Setting realistic, attainable goals facilitates this exercise. Goal setting is a dynamic process that involves both the individual and the nurse. Goals should be specific, concrete, measurable, and achievable. Nurses facilitate this process by respecting the individual's input and using a values clarification exercise (such as the one mentioned) to facilitate a more complete database to guide individuals to identify and prioritize problems to be addressed, and set mutually agreed on long-term and short-term goals. Nurses encourage individuals to challenge themselves when their behaviors are not consistent with what they identified as important and meaningful to them. For example, when an overweight man with hypertension and high cholesterol levels continues to smoke and eat high-fat foods, nurses help him to look at these behaviors relative to what is meaningful to him, such as his family. The cost and benefit are usually clear, and the responsibility for the change is with the individual, not the nurse. Nurses ask the following questions to help individuals clarify long-term goals:

- What is important to you?
- What would you like to change about your life?
- What can you do to start that change?
- When will you take that action?
- How will you measure success?
- How will you maintain the desired change?
- How can I help you to reach your goal?

Setting realistic, attainable goals helps to create a sense of confidence and achievement and to build enthusiasm to set future

goals. This process, in turn, increases a sense of control and mitigates the negative effects of stress.

Humor

Humor is an enjoyable and effective antidote to stress for many people. Humor can have health-promoting properties (Konradt et al., 2013; Stuart, 2013). When acting as a stress reducer, humor produces laughter. Laughter creates predictable physiological changes in the body. Similarly to how it behaves with other forms of exercise, the body responds in two stages: an arousal phase with an increase in physiological parameters, and a resolution phase, during which these parameters return to resting values or lower values (Wooten, 2009).

Humor can open different perspectives on problems and facilitate objectivity, which increases a sense of self-protection and control. Finding humor in a stressful situation can help people to reframe perceptions of the event. Some hospital staffs are using laughter libraries, humor rooms, comedy carts that can be wheeled into an individual's hospital room, and clowns to bring laughter and joy to the bedside. Humor has potential as an accessible, enjoyable, and inexpensive stress-reduction strategy that can offer people new perspectives on their world and themselves. Nevertheless, recognizing that humor can mask conflict or be hurtful is critically important in judging when and how to use it in clinical and work setting encounters (Box 13-9).

Box 13-9

Humor Strategies for Stress Reduction

Nurses help individuals use humor for health promotion and stress reduction in a variety of ways, including:

- Keeping a humor journal: looking for the unintentional amusing remark, watching for funny things young children say or do, and looking in the newspaper for humorous grammatical errors or an inappropriate choice of words and writing them in a journal

- Looking on the Internet for humorous resources
- Creating a scrapbook of humorous cartoons, pictures, stickers, poems, and songs
- Reading a cartoon or joke in the newspaper every day and sharing it with a friend
- Watching funny movies or reruns of old television programs
- Finding and spending time with funny, light-hearted people

For more information about using humor to reduce stress, see Box 6-4.

Engaging in Pleasurable Activities

A variety of activities can promote the relaxation response. Finding activities that are enjoyable to the person can be a key strategy to reduce stress and promote healthy behaviors. For example, Wong in her engaging book *Scales to Scalpels* (Wong & Viagas, 2012) described how the Longwood Symphony Orchestra in Boston, a talented group of medical professionals who practice at an elite center of health care and research, helps them to thrive as artists. Carving out the time to create music within this ensemble in the midst of demanding clinical and academic lives allows these musician/clinicians to practice the healing art of music for themselves and in turn to be better healers. Wong's engaging narrative underscores the value of integrating various art therapies into our care plans as a valuable strategy for health promotion and stress reduction. Additionally, it points to the importance of self-care for clinicians.

Effective Coping

When people believe that they can cope effectively, the harmful effects of stress can be minimized. The stressful situation is perceived as a challenge rather than a threat. This often elusive difference has vital mind, body, and spirit effects. When people believe that their lives are more balanced and under control, they are productive, but not driven; are aroused, but not anxious; and may even be physically or mentally tired, but not exhausted.

Effective coping helps people face great adversity (such as illness) and recognize the opportunity that the situation often presents. First and foremost, individuals must recognize that coping is the ability to find a balance between acceptance and action, between letting go and taking control. Many stress-management strategies help individuals distinguish these differences by providing a format for observing or objectifying their experiences. Other strategies such as exercise and balanced nutrition help individuals promote physical health and well-being to counter the harmful effects of stress. In addition, epigenetics (i.e., how environmental factors such as nutrition and stress trigger or mute the expression of genetic traits) is a vast canvas for the exploration of causes and intervention across a variety of physical and mental health disorders for individuals and populations (Dauncey, 2014) (Box 13-10: Genomics).

Box 13-10

Genomics

Epigenetic regulators modify gene expression without changes in DNA sequence. Nutrition is such a regulator that affects the brain throughout life, with profound implications for cognitive decline and dementia. Effects are mediated by changes in expression of multiple genes, and responses to nutrition are in turn affected by individual genetic variability. Epigenetic mechanisms are central to brain development, structure, and function. Epigenetics promote cell-

specific and age-related gene expression that can be highly stable but also reversible in response to factors such as nutrition. Health and brain function, in particular, result from highly complex interactions between numerous genetic and environmental factors, including nutrition, physical activity, age, and stress. The **interplay** of genetic and environmental factors, including nutrition and stress, is critical to our understanding the causes of many health disorders and developing effective interventions.

Modified from Dauncey, M. J. (2014). Nutrition, the brain and cognitive decline: Insights from epigenetics. *European Journal of Clinical Nutrition, 68*(11), 1179–1185.

Nurses help individuals improve effective coping by guiding them in the art of choosing the right strategy at the right time. In doing so, people gain a sense of control that minimizes or buffers harmful effects of stress. Nurses use the interventions described in this chapter to assist individuals to manage extrinsic and intrinsic stressors.

When individuals cannot control or influence the situation (extrinsic stressors), nurses advise them to do the following:

- Take care of physical health and well-being: exercise; eat healthy, balanced meals; and practice sleep hygiene.
- Accept: learn to accept that some situations or people cannot be changed or avoided. Forgiveness and letting go of resentment are often a part of acceptance.
- Use distraction: distraction involves putting a worry aside, when necessary, until the situation can be dealt with directly. This prioritizing is quite different from procrastinating or denial, because it is a necessary delay rather than avoidance.
- Reduce emotional arousal: practice mini relaxations, listen to a relaxation recording, use the four-step cognitive-behavioral restructuring technique, exercise, seek social support, pray, meditate, use humor and affirmations, write in a journal, or engage in a healthy pleasure.

When individuals can alter or influence the situation, or when they are contributing to or creating the stress (intrinsic stressors), nurses

advise them to do the following:

- Take care of physical health and well-being: exercise; eat healthy, balanced meals; and practice sleep hygiene.
- Reduce emotional arousal: practice mini relaxations, listen to music or a relaxation DVD or CD, engage in exercise, seek social support, pray, meditate, use humor and affirmations, write in a journal, engage in a healthy pleasure, and/or use the four-step cognitive-behavioral restructuring strategy:

- *Stop* (breaking the cycle of escalating, negative thoughts)
- *Breathe deeply* (eliciting the relaxation response and releasing tension)
- *Reflect* (asking "What is going on here? What am I thinking? Is the thought true? Is the thought helpful? Am I jumping to conclusions or magnifying the situation?")
- *Choose* a more realistic, rational response and related behavioral reaction.

- *Problem-solve:*

- Clarify values, beliefs, and expectations.
- Gather information.
- Seek advice, support, assistance, or information.

- Use assertive communication and empathy.
- Set realistic goals, design action strategies, and determine the best steps to handle the problem.
- Take action.

See the care plan for John DeMarco for an example of a plan for effective coping.

Case Study

Health Assessment: John DeMarco

John DeMarco, a 29-year-old man separated from his wife, walked into the health maintenance organization stating he had a severe sore throat, could not eat, had not worked for a day, and was feeling "awful." He wanted to see the physician and get a prescription for an antibiotic. The medical record revealed two episodes within the last 9 months of reports of a sore throat, culture of organism, and antibiotic treatment. The separation from his wife occurred 1 year ago. He had not had a physical examination in 2 years. During the assessment interview, the nurse gathered the following information: John DeMarco appeared tired; he presented his problem in short, terse statements; he was irritable about the clinic's slow service; and he expressed a need to get back to work. Within the last 3 weeks he had been required to work overtime because he faced deadline penalties, and his boss said that Mr. DeMarco's promotion, due in 2 months, depended on his performance now. The company is struggling, and layoffs may be pending. Mr. DeMarco said that, in general, things were fine. His wife was apparently happy without him, and he was too busy to care or to think about that relationship. He made one remark about his boss: "What do you do with a nervous boss?" He described his diet as fast food "taken on the run." He said he gets

about 6 hours of sleep per night and awakens one to two times near morning. He has infrequent contact with family members, who live in the area. In accordance with the clinical protocol for the health center, the nurse collects a throat culture.

Reflective Questions

- As Mr. DeMarco's nurse, how would you comprehensively assess his health?
- What are several different diagnoses and possible individual, family, and etiological factors to consider?
- What work-related health issues may be a concern?
- What other issues may impact the community where Mr. DeMarco is employed?

Care Plan

Plan for Effective Coping: John DeMarco

***NURSING DIAGNOSIS: Ineffective coping related to increased stress at work and limited coping strategies**

Defining Characteristics to Assess

- Physiological disturbances
- Abuse of alcohol or drugs
- Participation in potentially dangerous activities
- Engaging in lifestyle with risk to health
- Impairment of social role functioning:

- Nonproductive lifestyle
- Failure to function in usual social roles
- Nonperformance of activities of daily living
- Inappropriate behaviors in social situations
- Self-absorption
- Lack of concern for or detachment from usual social supports
- Poor morale:
- Unhappiness
- Lack of future orientation
- Hopelessness
- Unacceptable quality of life
- Pessimism
- Defensive patterns:
- Inflexibility
- Hypervigilance

- Avoidance
- Inertia
- Refusal or rejection of help

Expected Outcomes

Mr. DeMarco will:

- Report increased information on and consequences to himself of stressors experienced.
- Practice the relaxation response for 20 to 30 minutes every day through prayer or contemplation; use multiple mini relaxations throughout each day.
- Report increasing weekly exercise or activity and healthy changes in nutrition and sleep or rest patterns.
- Develop effective coping and problem-solving abilities to manage stress, beginning with the stress at work.
- Evaluate the result of throat culture and consult with his primary care provider if the result is positive and an antibiotic is indicated.

Interventions

- Promote an attitude of openness to new information.
- Enroll him in a cognitive-behavioral group program to learn stress-management strategies and health promotion.
- Monitor his daily practice of relaxation response.
- Monitor his changes in exercise or activity, nutrition, sleep or rest

patterns, and mood.

- Guide him to develop two coping strategies through cognitive-behavioral restructuring.
- Schedule a follow-up appointment or telephone check-in to monitor his well-being.

---

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Health and the ability to cope effectively with the many demands of work-life balance require management of stress. Combining careful assessment and choice of strategies, thoughtful and honest feedback, and continued support, nurses assist people to cope more effectively with the innumerable actual and potential stressors they may encounter. Research to discern the interplay of homeodynamic physiological, psychological, social, and spiritual responses to stress has yielded important knowledge for practice. However, uncovering the intricate workings of the brain within the context of human stress and coping experiences is a daunting and critical challenge for today's health researchers.

Stress-management strategies provide an opportunity for individuals to acquire the necessary skills to cope more successfully and become confident in self-management. Such awareness enables the individual to challenge and change perceptions, decrease stress reactivity, improve self-management skills, and minimize the harmful consequences of stress. This process positively influences health promotion, disease prevention, and symptom management. Challenges remain to expand intervention testing to families and communities. Understanding the influences of stress on health and illness is essential to all nursing practice.

Complementary and Alternative Strategies

Donna DelloIacona

OBJECTIVES

After completing this chapter, the reader will be able to:

- Compare holistic, allopathic, and complementary and alternative health modalities.
- Describe the nursing role in complementary health therapies.
- Explain the origin and practice of selected holistic health strategies.
- Identify complementary and alternative medicine resources and guidelines.
- Discuss complementary and alternative medicine safety and effectiveness.

KEY TERMS

Acupressure

Acupuncture

Affordable Care Act

Think About It

Ms. Gonzalez is 45 years old in her usual state of good health working as a teacher, until she receives a diagnosis of with lung cancer. She has never smoked, has no family history of smoking, but worked as a waitress in a diner for 10 years as a young woman. Smoking in restaurants was not restricted at that time. Her presenting symptoms were hemoptysis, low-grade fever, fatigue, and persistent cough. Her family and friends are very concerned and have provided her with various complementary and alternative medicine (CAM) modalities to help to treat her. She goes to the preoperative clinic for surgery, and in addition to 650 mg aspirin she has been taking coenzyme Q_{10}, amygdalin/laetrile, milk thistle, and green tea as treatment for her cancer and kava kava to help her relax and rest since her diagnosis. She has begun yoga classes at a local spa. She is frightened, and she believes that she feels less fatigued since starting these therapies. She has never taken prescription medications and is afraid of addiction if she takes prescribed pain medication. The local hospital offers a center for wellness classes involving alternative and complementary therapies, including reiki, yoga, acupuncture, massage, and dietary supplements, to assist with treatment effects. She understands that these complementary therapies may help relieve her symptoms, but she believes they will also treat her cancer. After looking at sites on the Internet, including http://cam.cancer.gov and http://www.nccih.gov, she feels overwhelmed and confused as to what is best for her.

- What is the difference between reiki and massage?
- What occurs in a usual visit for acupuncture or a reiki session?
- How do these therapies work?
- Are these therapies evidence-based?

- What is the best understanding of the biological and physiological mechanisms for these therapies?
- What is the best understanding of the safety of these therapies?
- Which therapies are covered by her insurance?
- Would Ms. Gonzalez's therapies be considered complementary, alternative, or integrative?

Background

Although many complementary and alternative therapies date back more than 5000 years to the Han Dynasty, Hippocrates, and Indian cultures with Ayurveda, only a few have been evaluated with well-conducted research (National Center for Complementary and Integrative Health [NCCIH], 2015b). In the United States the CAM movement is far more modern, with herbal agents used by Native Americans, chiropractic, meditative, and a variety of therapies beginning in the 19th century. The first center for alternative medicine, the Office of Alternative Medicine, was commissioned by Congress only in 1991(NCCIH, 2015b). The working definition of CAM at that time was "a group of medical, health care, and healing systems other than those included in mainstream health care in the United States" (NCCIH, 2015b). CAM now includes an ever-increasing array of theories, modalities, products, and practices that are used to treat illnesses and/or promote health and well-being.

The field is broad and constantly changing, but an authoritative and governmental source, the National Institutes of Health's **National Center for Complementary and Integrative Health** (NCCIH), currently defines CAM as "a group of diverse medical and health care systems, practices, and products that are not generally considered part of conventional medicine or Western allopathic medicine and the traditional medical providers in the United States health care system" (NCCIH, 2015b). NCCIH has separate definitions of complementary, alternative, and integrative therapy. It defines **complementary therapy** as the use of CAM in conjunction with and as a complement to allopathic traditional medicine. One example is the use of acupuncture to help lessen some side effects of cancer treatment. **Alternative therapy** uses CAM instead of standard medicine. One example is the use of a special diet or herbs to treat cancer instead of anticancer drugs prescribed by an oncologist. **Integrative therapy** is a total approach to medical care that combines standard medical and surgical interventions with the CAM practices that have been shown

to be safe and effective. They treat the client's mind, body, and spirit. There is an emphasis on safety and effectiveness (NCCIH, 2015c). Complementary and alternative therapies are more holistic than traditional medicine practices have been in the past. The most common of these from a national survey can be seen in Figure 14-1.

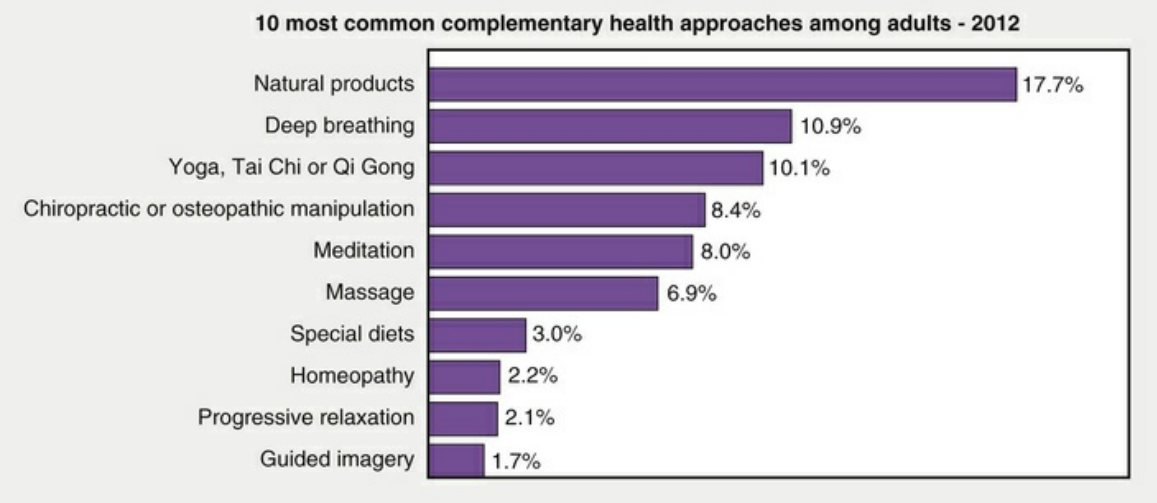

FIGURE 14-1 Ten most common complementary health approaches among adults. (From Clarke, T. C., Black, L. I., Stussman, B. J., Barnes, P. M., & Nahin, R. L. [2015]. *Trends in the use of complementary health approaches among adults: United States, 2002–2012. National health statistics reports no. 79.* Hyattsville, MD: National Center for Health Statistics. http://www.cdc.gov/nchs/data/nhsr/nhsr079.pdf.)

Although heterogeneous, the major CAM systems have many common characteristics, including a focus on individualizing treatments, treating the whole person, promoting self-care and self-healing, and recognizing the spiritual nature of individuals. A large gap exists between our current level of scientific evidence and what we need to provide to clients in terms of evidence-based advice. More rigorous scientific research is being conducted by many countries to enrich our knowledge base.

Some Known Facts

- The World Health Organization estimates that more than 80% of the

world's population uses some form of herbal medicine.

- Seventy-five percent of Americans use some herbal supplement; most do not report them to providers.
- Approximately 26% of people scheduled for surgery use herbal products that have an adverse impact on their surgical outcome; 19 agents are associated with abnormal bleeding (Wong et al., 2012).
- Accurate risk assessments are unknown as there is:

- No regulation of these agents.
- No standard manufacturing process.
- No method to determine ingredients.
- No quality controls.
- No protection against contamination.
- No Food and Drug Administration (FDA, 2015) required reporting of adverse reactions from alternative therapies.
- No evidence base for most of the claims.

- A large national survey found that:

- Seventy-seven percent of Americans believed that the government reviewed the safety of supplements and approved them before they were marketed.

- Sixty-eight percent of Americans believed that supplements had to list potential side effects on their labels.

- Fifty-five percent of Americans believed that supplement labels could not make claims of safety without scientific evidence.

- Americans were unaware that herbal-pharmaceutical interactions occur (Clarke et al., 2015).

What Is the Difference Between Holism and Allopathy?

Health care and delivery in the United States is most often **allopathic medicine,** a system in which physicians and other health care professionals, such as nurses, pharmacists, and therapists, treat symptoms and diseases using medications, radiation, lasers, or surgical interventions. **Allopathy** is also called biomedicine, conventional medicine, mainstream medicine, orthodox medicine, and Western medicine (NCCIH, 2015c).

Holistic health considers the whole person and how he or she interacts with his or her environment. It emphasizes the connection of mind, body, and spirit. **Holistic health** is a system of preventive care that takes into account the whole individual, one's own responsibility for one's well-being, and the total influences—social, psychological, environmental—that affect health, including nutrition, exercise, and mental relaxation. **Holism** entails a focus on proactive, healthy living and considers not only prevention of illness but also the root cause of the illness. When disease occurs, holistic practitioners seek to support the person's natural healing systems, to consider the whole person, and to consider the environment, both physical and mental, surrounding the person. This movement in the healing arts reflects the theory of holism and recognizes that all aspects of the person must be considered when care is being planned and delivered (NCCIH, 2015c).

Person-Centered Care

There are a variety of reasons why people seeking care seek a more holistic approach to care, and use CAM. Those receiving traditional medicine therapies are often disappointed in the lack of effective treatments or cures for many disorders, have fear of the safety and long-term effects of “drugs” or treatments, believe herbal products are safe because they are derived from “nature,” and have a desire to have control of their own health, so they choose alternative and/or

complementary methods. There is a great deal of advertising, media, and peer influence that impacts their holistic choices.

Many people are seeking alternative styles of health care that focus on seeing care recipients as whole people, increasing well-being, and giving them greater control over self-care. The 2012 National Health Interview Survey (NHIS) (Clarke et al., 2015) identified that people in the United States use CAM modalities and they spent $33.9 billion out-of-pocket on CAM. CAM costs are 11.2% of total out-of-pocket expenditures on health care. The $14.8 billion spent on nonvitamin, nonmineral, natural products is equivalent to approximately one-third of the total out-of-pocket spending on prescription drugs ($47.6 billion), and the $11.9 billion spent on CAM practitioner visits is equivalent to approximately one-fourth of the total out-of-pocket spending on physician visits ($49.6 billion) (NCCIH, 2015d).

CAM practices are moving into mainstream medical practice. Many traditional medical centers now include a holistic viewpoint and integrative therapies, including Harvard, Stanford, Duke, and the Mayo Clinic. Most of them offer acupuncture, massage, healing gardens, and nutrition counseling. The Van Elslander Cancer Center at St. John Hospital and Medical Center in Detroit, Michigan, has a clinic that also offers qigong, tai chi, yoga classes, hypnotherapy, and guided imagery (St. John Providence, 2015). With a vision "to promote health and healing of body, mind, and spirit," the Woodwinds Health Campus located in Woodbury, Minnesota, offers complementary therapies, including the use of essential oils, energy-based therapies, imagery, music, acupuncture, acupressure, and massage (Woodwinds Health Campus, 2015). The Birchtree Center in western Massachusetts offers professional holistic development classes for nurses that can help them prepare for holistic nursing certification (Birchtree Center, 2015).

At the Dana Farber Cancer Institute in Boston, Massachusetts, the Eleanor and Maxwell Blum Patient and Family Resource Center provides individuals undergoing cancer therapies and their family members with a comfortable environment to learn more about disease treatment and management, including nutrition, palliative care,

spirituality, stress management, and emotional health (Dana-Farber Cancer Institute, 2016). This integration of holistic practices with standard allopathic medicine (Box 14-1: Genomics) serves to introduce more people to complementary therapies and may give these practices more credibility, especially with those who currently question their value. Alternative/complementary therapies are used as an adjunct to conventional medical care, and many are now covered by insurers, meet consumer demand, and thus satisfy the definition of patient- or person-centered care.

Box 14-1

Genomics

Genetics contributes to people's risk of developing many common diseases. Diet, lifestyle, and environmental exposures are factors in many conditions, and risk factors for many types of cancer. A better understanding of the interface of CAM practices with genetics may identify measures to mitigate health risks. Mapping the genetic components of cells, explaining how all the various elements work together to affect the human body in both health and disease, and developing targeted therapies will help providers better educate and advise those in their care.

Health and Wellness

The World Health Organization's timeless definition of **health** is "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (World Health Organization, 1948). The Wellness Initiative (Substance Abuse and Mental Health Services Administration, 2015) defines **wellness** as "overall well-being. It includes the mental, emotional, physical, occupational, intellectual, and spiritual aspects of a person's life." Working toward health and wellness is an ongoing process that includes self-knowledge and self-care (Definition of Wellness, 2015). The wellness-related reasons that people use a variety of nontraditional therapies analyzed for this report include:

- Treatment of a specific health condition
- General wellness or disease prevention
- Improve immune function
- Improve energy
- Focus on the whole person—mind, body, and spirit
- Improve memory or concentration

Use of holistic modalities can also help meet the goals of *Healthy People 2020* (United States Department of Health and Human Services, 2015). This includes increasing quality and number of years of life, improving nutrition, increasing physical activity, and decreasing illegal substance abuse and harassment throughout the life span (Box 14-2: *Healthy People 2020*). The Affordable Care Act includes provisions that allow CAM providers to participate in health care delivery teams.

Box 14-2

Healthy People 2020

Selected National Health and Wellness Objectives

- (Developmental) Increase the proportion of insured persons with coverage for clinical preventive services.
- (Developmental) Increase the proportion of persons who receive appropriate evidence-based clinical preventive services.
- Increase the proportion of adolescents who have had a wellness checkup in the past 12 months.
- Increase the proportion of schools with a school breakfast program.
- Reduce the proportion of adolescents who have been offered, sold, or given an illegal drug on school property.

- Increase the proportion of adolescents whose parents consider them to be safe at school.
- (Developmental) Increase the proportion of middle and high schools that prohibit harassment on the basis of a student's sexual orientation or gender identity.
- Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, HIV/AIDS, and infection with sexually transmitted diseases; unhealthy dietary patterns; and inadequate physical activity.
- Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal health and wellness in the following areas: hand washing or hand hygiene; oral health; growth and development; sun safety and skin cancer prevention; benefits of rest and sleep; ways to prevent vision and hearing loss; and the importance of health screenings and checkups.
- Increase the proportion of college and university students who receive information from their institution on each of the priority health risk behavior areas (all priority areas; unintentional injury; violence; suicide; tobacco use and addiction; alcohol and other drug use; unintended pregnancy, HIV/AIDS, and infection with sexually transmitted diseases; unhealthy dietary patterns; and inadequate physical activity).
- (Developmental) Increase the proportion of work sites that offer an employee health-promotion program to their employees.
- Increase the proportion of persons who report that their health care providers always involved them in decisions about their health care

as much as they wanted.

- (Developmental) Increase the proportion of individuals whose physician recommends personalized health information resources to help them manage their health.
- Increase the proportion of adults who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.
- Increase the proportion of adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.
- Increase the proportion of physician office visits that include counseling or education related to physical activity.
- Health-related quality of life and well-being is a new topic area for *Healthy People 2020.* Health-related quality of life is a multidimensional concept that includes domains related to physical, mental, emotional, and social functioning. It goes beyond direct measures of population health, life expectancy, and causes of death, and focuses on the impact health status has on quality of life. A concept related to health-related quality of life is well-being, which assesses the positive aspects of a person's life, such as positive emotions and life satisfaction.

Health Policy

Clinical Practice Guidelines

Clinical practice guidelines for CAM modalities exist to identify and describe evidence-based recommended courses of intervention in general (NCCIH, 2015g,i) and for specific disorders (Tables 14-1 and 14-2). See Box 14-3: Quality and Safety Scenario for guidelines on

quality and safety and Box 14-4 for a partial list of NCCAIH practice guidelines to provide best evidence-based practice support. Deng and colleagues (2013) provided more than a dozen alternative and complementary therapies to be included in the diagnosis and management of the disease process.

TABLE 14-1

Herbs as Medicine

Drug Name	Plant/Tree
Digitalis (heart drug)	Foxglove plant
Paclitaxel (cancer drug)	Pacific yew tree
Aspirin	Willow tree
Quinine (malaria drug)	Cinchona tree
Morphine	Opium poppy
Galantamine (Alzheimer disease drug)	Daffodil bulb
Vincristine (cancer drug)	Rosy periwinkle
Reserpine (blood pressure drug)	Indian snakeroot plant

What are herbs? An herb (also called a botanical) is a plant or plant part used for its scent, flavor, and/or therapeutic properties. An herbal supplement is a type of dietary supplement that contains herbs, either alone or in mixtures.

From National Center for Complementary and Integrative Health. *Herbs at a glance.* http://nccam.nih.gov/sites/nccam.nih.gov/files/herbs/NIH_Herbs_at_a_Glance.pdf.

TABLE 14-2

Commonly Used Herbs: Safety Profile

Herb	Uses	Side Effects	Interactions	Evidence
St. John's wort	Depression	Dizziness, restlessness, sensitivity to sunlight, sleep disturbances, constipation	Seizure medications, alcohol, warfarin, calcium channel blockers, digoxin, oral contraceptives, statins	No statistically significant effect other than placebo effect on depression scores
Ginseng	Depression, anxiety, energy, concentration, immunity	Chest pain, headache, hypertension, impotence, palpitations,	Diabetic agents, including insulin	Some evidence for concentration, no benefit for energy, mood, or immune modulation
Milk thistle	Liver ailments	Laxative effects	Flagyl	Cirrhosis; patients may have longer survival; may be protective

				against hepatotoxic agents
Black cohosh	Menopausal symptoms	Low blood pressure; dizziness	Iron, antihypertensive drugs, warfarin, aspirin	No better than placebo
Echinacea	Immune system booster	Well tolerated	Immunosuppressants	Decreases time to resolution of symptoms; no preventative effect
Saw palmetto	Benign prostate hyperplasia	Abdominal issues headache, urinary retention	Hormones: leuprolide, birth control agents	As effective as many prescribed medications for benign prostate hyperplasia
Gingko biloba	Memory, asthma, vision	Gastrointestinal upset, seizures, bleeding or bruising	Anticoagulants, warfarin, aspirin, acetaminophen, seizure medications, antidepressants	No measurable long-term benefit
Garlic	Asthma, diabetes, high cholesterol level, cancer	Dizziness, rash, diaphoresis, bleeding	Antiplatelet drugs, warfarin, aspirin, HIV medications	No long-term benefits
Cranberry	Urinary tract infection, cancer	Diarrhea	None	Reduces risk of infection; no effect on treatment
Soy	Menopause, cancer, heart disease		Antibiotics, estrogens, warfarin, tamoxifen, losartan, carvedilol, levothyroxine	No effect on blood pressure Inconclusive results for hot flashes to date
Fish oil	Cholesterol; blood pressure, and heart disease	Prolonged bleeding, negative impact on immunity	Anticoagulants, birth control agents	May worsen depression
Glucosamine	Joint health	Gastrointestinal upset	Blood thinners, insulin, heart medications	Those with a shellfish allergy should avoid it
Coenzyme Q_{10}	Heart, fatigue, immunity	Rash, gastrointestinal upset	Chemotherapy, blood pressure medications, coumadin	
Ephedra	Weight loss	Heart attack; respiratory depression, death	Theophylline, digoxin, caffeine, but available on the Internet	Banned by the US Food and Drug Administration in 2003

Box 14-3

Quality and Safety Scenario

How Should Complementary and Alternative Medicine Be Evaluated?

- What standards of proof should the nurse require before adopting an alternative/complementary therapy in clinical practice?
- Have all (or even some) of the alternative/complementary therapies commonly used by nurses today been subjected to these standards?
- Have all (or even most) of the standard therapies commonly used by nurses and medicine today been subjected to these standards?
- Government and consumer advocates are beginning to require the same oversight, regulation, and monitoring of some CAM practices.

Healthy People 2020

Holistic interventions are used to promote wellness and are used to meet the *Healthy People 2020* vision of improving the health of Americans and helping them live long and healthy lives. Many CAM modalities support the mission and its overarching goals. Examples include increasing physical activity and flexibility in all age groups, decreasing pain, and reducing substance abuse (http://www.healthypeople.gov).

Affordable Care Act and National Prevention Strategy

The **Affordable Care Act** (https://www.healthcare.gov) mandates that insurers not discriminate against licensed health care providers, including those who practice alternative medicine, such as naturopaths, massage therapists, and acupuncturists. CAM practitioners and integrative practices are mentioned in several areas of the law, including workforce planning; patient-centered medical homes; wellness, prevention, and health-promotion services; comparative effectiveness research; and birthing services. The **National Prevention Strategy,** released in June 2011 as a result of the Affordable Care Act, has the following four strategic directions:

- Healthy and safe community environments: Create, sustain, and

recognize communities that promote health and wellness through prevention.

- Clinical and community preventive services: Ensure that prevention-focused health care and community prevention efforts are available, integrated, and mutually reinforcing.
- Empowered people: Support people in making healthy choices.
- Elimination of health disparities: Eliminate disparities, improving the quality of life for all Americans.

The second direction has a holistic objective: "enhance coordination and integration of clinical, behavioral, and complementary health strategies." Inclusion of CAM into future research and evaluation and integration into care are mentioned several times throughout the document (National Prevention Council, 2011).

Nursing and Nursing Education

A variety of holistic, complementary, and alternative practices are now very prevalent and part of mainstream health care practice; therefore nurses must understand the nature of these interventions to provide safe, effective care and to discuss these practices with individuals who are using them so as to facilitate integrative care. Nurses who understand holistic practices will be able to make appropriate referrals to alternative/complementary practitioners. Nurses also find that holistic interventions such as **energy work**, bodywork, aromatherapy, prayer, meditation, massage, imagery, music therapy, and the movement arts of yoga, tai chi, and qigong provide a useful adjunct to current nursing theory (Dossey & Keegan, 2013) and practice.

The **American Holistic Nurses Association** (AHNA) defines holistic nursing as nursing practice that heals the whole person. It is a "specialty practice that draws on nursing knowledge, theories, expertise and intuition to guide nurses in becoming therapeutic partners with people in their care. This practice recognizes the totality of the human being—the interconnectedness of body, mind, emotion, spirit, social/cultural, relationship, context, and environment" by

integrating CAM modalities into clinical practice to broaden and enrich nursing treatment of physiological, psychological, and spiritual needs. Florence Nightingale is thought to be one of the first holistic nurses because she believed in care of the person, focusing on unity, wellness, and the interrelationship of human beings with their environment. Holistic therapy is considered an "attitude, a philosophy, a way of being" although some holistic nurses specialize in one or more modalities (AHNA, 2015a,b; Dossey & Keegan, 2013).

The AHNA "advances the profession of holistic nursing by providing continuing education in holistic nursing, helping to improve the health care workplace through the incorporation of the concepts of holistic nursing, educating professionals and the public about holistic nursing and integrative health care, and promoting research and scholarship in the field of holistic nursing" (AHNA, 2015a). The AHNA website offers a variety of resources, including a directory of holistic practitioners based on modality and location, descriptions of healing modalities (AHNA, 2015a,d), and guidance on starting a holistic private practice.

Interventions

NCCIH divides CAM modalities into several loose domains and an additional "whole medical system category" that incorporates all domains. The domains are not formally defined but include biologically based practices, mind and body techniques, manipulative body-based practices, energy therapies, and ancient medical systems. See Table 14-3 for examples of these categories. These domains are neither mutually exclusive nor mutually inclusive because many could belong to several categories.

TABLE 14-3

Categories and Examples of Complementary and Alternative Therapies

Whole medical systems	Chinese, ayurvedic, traditional/folk healers, naturopathy, homeopathy
Biologically based practices	Herbal remedies, vitamins, dietary supplements, diets, probiotics, chelation therapy, hydrotherapy, aromatherapy
Manipulative and body-based practices	Massage, reflexology, chiropractic, craniosacral therapies, physical therapy
Mind-body techniques	Meditation, guided imagery, hypnosis, music, biofeedback, yoga, tai chi, qigong, acupuncture, dance
Energy therapies	Magnetic field therapy, reiki, therapeutic touch, prayer

Because each modality has its own identified guidance for purpose, efficacy, and safety, this section will not be specific but will briefly define many of the modalities and highlight a few of the more common ones with current known evidence.

Whole Medical Systems

Whole medical systems are complete systems of theories and practices that have evolved culturally over time, and because they are different from Western allopathic medicine, they are considered CAM. Examples include traditional healers and traditional or folk healers. The 2012 NHIS (Clarke et al., 2015) found that although there was less use of traditional healers than in 2007, there was an increase in the use

of most other CAM modalities.

Ayurvedic Medicine

Ayurvedic medicine has evolved over thousands of years in India. This treatment utilizes herbs in their natural state, as prepared herbal drugs, massage, and special individualized diets, based on the seasons of one's life and one's constitutional type; there are ten. Ayurvedic supplements can be made either of herbs only or a combination of herbs, metals, and minerals. Some of these products may be harmful if used improperly or without the direction of a trained practitioner (NCCIH, 2015a).

The goals are treatment of disease, prevention of disease, and improving a person's quality of life, by balancing the body, mind, and spirit. Basic premises include the beliefs that all living and nonliving things in the universe are joined together and good health is achieved when one's mind and body are in harmony (NCCIH, 2015a). Two ancient books, more than 2000 years old and written in Sanskrit, are considered the heart of the practice and identify eight branches of ayurvedic medicine: internal medicine; surgery; treatment of head and neck disease; gynecology/obstetrics; pediatrics; toxicology; care of the elderly and rejuvenation; and sexual vitality. Treatment practices include eliminating impurities, decreasing symptoms, increasing resistance to disease, and reducing worry and increasing harmony. Nearly 80% of the Indian population continues to use ayurvedic medicine. No states in the United States currently license ayurvedic practitioners.

Traditional Chinese Medicine

Traditional Chinese medicine (TCM) has evolved over thousands of years in China and includes herbs, acupuncture, and other CAM treatments. The theoretical framework includes the complementary yet opposing yin and yang life forces, and the balance and harmony of the vital energy, or life force **(qi)**, circulating through the body's pathways. TCM describes the organs and tissues in the body through

corresponding elements of fire, earth, metal, water, and wood. It also uses eight principles to analyze symptoms and categorize conditions, including cold/heat, interior/exterior, excess/deficiency, and yin/yang (NCCIH, 2015e).

Naturopathy

Naturopathy, also called naturopathic medicine, evolved from a combination of traditional and other modalities in 19th-century Europe guided by the healing power of nature (NCCIH, 2015f). The underlying principles are first do no harm; illness is seen as a purposeful process of the organism; symptoms are viewed as life forces attempting to heal the organism. Practitioners do not use prescription drugs, injections, X-rays, or surgery, but instead implement a variety of CAM modalities, emphasizing the adoption of a healthy lifestyle, strengthening and cleansing the body, special diets, therapies, and use of manipulation and exercise (NCCIH, 2015f).

Homeopathy

Homeopathy principles have been documented since at least the time of Hippocrates, but not until early in the 19th century were they brought into modern usage. Samuel Hahnemann, a German physician and chemist, is credited with founding homeopathy (National Center for Homeopathy, 2015). When Hahnemann first named the discipline in 1807, mainstream medicine involved ineffective practices such as bloodletting and purging. Homeopathy treats the whole person and believes that symptoms are a body's effort to rid itself of disease. It is based on four principles: the law of similars, or like cures like; the minimum dose, determining the least amount of medicine needed to treat a disease; totality of symptoms, matching the complete symptom profile of the person to the symptom profile of the remedy; and single remedy, administration of one remedy at a time (National Center for Homeopathy, 2015).

Homeopathy is based on the whole person rather than on the symptoms. Treatment stimulates the body's healing ability through

the administration of small amounts of dilute substances that are believed to cause illness or symptoms. There is wider acceptance of homeopathy in other countries, including France, Germany, Mexico, Argentina, India, and Great Britain. The World Health Organization estimates that homeopathy is currently practiced by more than 500 million people worldwide. In April 2015 (National Center for Complementary and Integrative Health, 2015) the FDA held a hearing on homeopathic product regulation, safety, and efficacy. Most of the testimony cited the lack of scientific evidence, the lack of consumer understanding, the lack of regulation, and the harm that has come from some of these practices. Further analysis and decisions may be forthcoming.

Biologically Based Practices/Natural Products

Biological or natural products are the oldest form of CAM. Medicinal herbs were found in the personal effects of a mummified prehistoric man in the Italian Alps (NCCIH, 2015b). Botanical remedies were inventoried in great detail in the Middle Ages. The 2012 NHIS found that nearly 40% of American adults use natural products as CAM. This area of CAM includes nutritional counseling, herbs, vitamins, minerals, probiotics, and aromatherapy. According to NCCIH, daily multivitamin and calcium supplements are not thought of as CAMs.

According to the US *National Nutritional Research Roadmap* (Interagency Committee on Human Nutrition Research, 2015), **nutritional counseling** uses education and diet and supplementation therapeutically as the primary or adjunctive measure to prevent or treat illness. Multiple studies have demonstrated the efficacy of nutritional interventions, vitamins, therapeutic diets, and individual instruction. Diet teaching for those receiving hemodialysis showed efficacy in stabilization of laboratory values (Garagarza et al., 2015), and nutritional interventions for those undergoing chemotherapy not only helped people maintain weight and muscle mass but also improved survival over the control group (De Waele et al., 2015).

Herbal therapy is the use of herbs or their chemical properties to treat specific conditions or to enhance the function of various body

systems, such as boosting the immune system, treating allergies, or preventing a cold. Herbal medicines may act on the body like prescription drugs and may interact with prescription medications; thus it is important to elicit a full profile of what care recipients are taking and in what doses as part of medication reconciliation. A table of common agents, their common uses, side effects, and interactions, and the current evidence has been compiled from NCCIH data (NCCIH, 2015h); see Table 14-2.

Probiotics are live microorganisms found in the human digestive tract, such as "friendly bacteria." They are taken to enhance the digestive system either as a supplement or in natural forms, such as yogurt or other fermented foods.

Hydrotherapy, or water therapy, is the use of water at various temperatures or as ice or steam to relieve discomfort and promote physical well-being. Treatments include full-body immersion, hydrotherapy, steam baths, saunas, spas, and the application of hot and/or cold compresses.

Aromatherapy, also referred to as essential oil therapy, is defined by the National Association for Holistic Aromatherapy (2015) as the art and science of using naturally extracted oils from plants to balance, harmonize, and promote the health of body, mind, and spirit. The therapeutic use of the oils may be via inhalation, external application, or ingestion. The use of aromatherapy, like that of many CAMs, without professional clinical training is strongly discouraged. Individuals must be trained to know the specific warnings and contraindications for each oil, as well as to understand how to handle the oils.

Manipulative and Body-Based Practices

Manipulative and body-based practices focus on the manipulation of bones and joints, soft tissues, and the circulatory and lymphatic systems. According to the 2012 NHIS (Clarke et al., 2015) these ranked in the top 10 CAM therapies.

Spinal or Bone Manipulation

Spinal or bone manipulation is the application of controlled force on a bone or joint and is performed by chiropractors, physical therapists, osteopathic physicians, and some conventional physicians. Spinal manipulation was recorded in ancient Greece and became foundational to chiropractic and osteopathic medicine in the late 19th century.

Chiropractic medicine focuses on manipulation of the spine and joints, focusing on spinal alignment for optimal functioning. Chiropractors often integrate other CAMs such as massage, nutrition, and specialized kinesiology into their practice.

Cranial and craniosacral therapies also focus on a natural configuration of the skeletal system, focusing on the skull and flow of cerebrospinal fluid for the treatment of body imbalances. Craniosacral therapy originated in osteopathy and focuses on the bones of the cranium, spine, and sacrum, using gentle pressure to restore free movement of cerebrospinal fluid, allowing normal functioning.

Physical therapy integrates a variety of modalities, including massage, manipulation, heat and cold, movement, and electrical impulses, to treat the body after damage or injury, reduce swelling, relieve pain, and restore function and range of motion to the body.

Massage

Massage incorporates different techniques in the manipulation of muscles and soft tissues of the body, such as rubbing or kneading, to increase circulation, facilitate healing, and reduce stress and increase relaxation. It is one of the oldest therapies and is referred to in writing in ancient China, Japan, India, Egypt, Greece, and Rome. Even Hippocrates mentions it in his writings. Different types of therapies have different techniques and purposes, such as lymphatic therapy, neuromuscular therapy, and trigger point therapy.

Reflexology is mixed method of CAM as it involves a type of manipulation and the concept of energy fields. A reflexologist applies pressure with the thumbs to mapped points on the feet or hands, or

both, by pressing deeply into the point to release tension and stimulate circulation of blood, lymph, and energy. Reflexology is more than massage because practitioners believe that the points correspond to the organs of the body and that stimulating the points will stimulate the organs to heal (Reflexology Association of America, 2015).

Mind-Body Medicine

Mind and body practices focus on the interactions between the brain, the body, and behavior, using the mind to affect the body and the body to affect the mind. Categories include meditation, imagery, and various methods of body movement. This concept dates back 2000 years to TCM and ayurvedic medicine practices (NCCIH, 2015a). Hippocrates noted that treatment relied on attitude, environmental influences, and natural remedies. Deep breathing, meditation, yoga, guided imagery, and progressive relaxation were in the top CAM therapies according to the 2012 NHIS (Clark et al., 2015). **Visual or guided imagery** encourages individuals to relax by focusing on calming thoughts or experiences. **Imagery** is "a gentle but powerful technique that focuses and directs the imagination" so as to, among other things, promote a sense of well-being and to help people relax (http://www.healthjourneys.com/what_is_guided_imagery.asp). In a randomized control study (Bozas et al., 2015), men with prostate cancer and women with breast cancer undergoing chemotherapy had a better quality of life and less depression and there was some positive impact on laboratory values if they used relaxation training and guided imagery as compared with the control group.

Meditation

Meditation is a method of focused attention to increase relaxation, quiet the mind, and reduce stress. Although it is often a part of many religious cultures, it is not necessarily a religious activity and can be practiced while one is still or while one is active, such as during walking. Like massage, different types have a variety of purposes and

techniques. Breath meditation is the simplest because it can be done anywhere and can evoke the relaxation response (Box 14-5). It can be taught and is useful for anyone. Centering focuses on a chosen word. Mindfulness meditation is a way of paying attention to or being mindful of a variety of topics, such as thoughts, actions, or the environment. Walking meditation is a form of mindfulness because the individual is mindful of the interaction of the inner body, the external body, and the environment with each step.

Box 14-5

Teaching the Technique of Breath Meditation

- You may stand, sit, or lie quietly as you begin to focus on your breath.
- Inhale and feel the air come into your nostrils, move down your throat, and into your lungs. Do not try to control the breath. Just observe it.
- Exhale and feel the air move up from your lungs and into your throat. Feel the warmth of the exhaled air in your nostrils.
- Breathe. Feel the air move in and out. Concentrate on the breath. Do not try to control the breath. Just observe it.
- Continue watching the breath for 5 to 10 minutes. As other thoughts come into focus, notice them and let them go. Focus again on the breath.
- As you become comfortable with breath meditation, you may easily add simple imagery to this technique.
- As you inhale, imagine breathing in peace or love or wellness.

- As you exhale, imagine breathing out pain or sorrow or grief.
- As you inhale, breathe in whatever it is that you need.
- As you exhale, breathe out whatever you wish to be free of in your life.

Hypnotherapy is a form of guided relaxation and focused attention of the unconscious mind. It is used with differing success for memory recall of suppressed events and for behavior changes such as discontinuation of the use of tobacco products. **Biofeedback** is a relaxation technique concentrating on vital functions such heart rate, breathing rate, and blood pressure. This visualization identifies which actions can change the rates and is used for stress and an irregular heart rate. Neurolinguistic programming changes behavior by changing patterns of thinking and speaking (NCCIH, 2015a).

Movement Therapy

Movement therapies use movement and bodywork to promote physical, mental, emotional, and spiritual well-being. The movement arts such as qigong, tai chi, and yoga are helpful for body, mind, and spirit, and, although technically not energy work, do manipulate life energies. **Qigong** (pronounced chee gung) is part of TCM, combining relaxed movements with a meditative aspect and controlled breathing to move qi energy through the energy channels and increase vital energy. **Tai chi** (pronounced tie chee) began as a Chinese martial art and combines physical movement, breath control, and meditation in a dance-like sequence of poses based on the movements of animals. One pose flows into the next in a slow, relaxed, gentle, unbroken rhythm, bringing an awareness of the moment-to-moment state of the body and producing a meditative state.

Yoga is a meditative movement practice that originated in India as a form of spiritual practice and aids in flexibility, agility, balance, and relaxation. The postures have names such as proud warrior, waterfall, runner's pose, downward-facing dog, mountain pose, and eagle pose.

There are many types and branches of yoga. Several studies of individuals with a variety of diagnoses have documented several health-related benefits from the practice of yoga, including reducing stress and anxiety, improving pain management, increasing flexibility, and increasing strength (Clarke et al., 2015; McCall et al., 2015). The 2012 NHIS (Clarke et al., 2015) reported yoga use up from 6% in 2007 to almost 10% in 2015. Given the increase in this practice in traditional medicine centers, the prevalence of yoga will likely rise.

Dance therapy is another movement-based mind-body modality, using dance to allow the body and mind to move freely in response to music.

Energy Therapies

Energy healing or therapy is practiced in many cultures and involves the use of assumed energy fields to heal and maintain wellness (Box 14-6). Believers in energy therapy describe disruptions in the energy field as a cause for illness and teach that balancing energy can aid in healing when this is done by an energy practitioner. Certain types of body energy are well known. Electrical energy in the body is reflected in diagnostic studies, including electrocardiographic, electromyographic, and electroencephalographic tracings. Nerves and cells have an electromagnetic action potential. Magnetic resonance imaging uses powerful magnets to measure the array of charged particles in the human body and produce diagnostic images. People can be affected by the energy of their environments, including the energy of other people. For example, anxiety is contagious and moves readily and quickly from person to person.

Box 14-6

Feel Your Own Energy

This exercise will help you feel your own energy, or chi.

- Sit quietly, back straight, feet touching the floor.

- Place your hands in your lap.
- Take a few deep breaths. Become quiet and still.
- Breathe slowly in and out for a few minutes.
- Slowly raise your hands in front of you, palms facing you, hands approximately 15 inches apart. Cup your fingers as though you are holding a basketball between your hands.
- Concentrate on the space between your hands. What is there? Can you feel anything?
- Slowly bring your palms closer together, focusing on the space between your hands.
- Can you feel warmth? Does it feel spongy? Can you move your hands around a shape?
- What you are feeling is the energy coming from the energy centers in your hands. Focus on the energy. Try to increase the sensation of fullness in the space between your hands.
- If you do not feel anything immediately, bring your hands back out to 15 inches apart and slowly move your hands together again. Try this no more than three times each time you attempt the exercise.

There are medical uses for energy that come from the environment. The energy of radiation is used to shrink tumors; sound energy, in the form of ultrasound waves, is used to break kidney stones. Lasers, focused light energy, are used in many types of surgery and to treat disorders such as psoriasis (Neumayer & Vargo, 2012). Light energy is useful in treating seasonal affective disorder. Color, another form of light energy, has been shown to have an effect on emotions and behaviors.

Energy fields may be characterized as measurable or as yet unmeasured. Practices based on measurable forms of energy include

those involving electromagnetic fields such as magnet therapy and light therapy. Practices based on other energy fields, also called biofields, generally reflect the concept that human beings are infused with subtle forms of energy, and various CAM therapies aim to treat these biofields (NCCIH, 2015b).

Any illness, stress, emotional upset, or spiritual distress can affect the flow of life energy. These disruptions in the flow of life energy can cause or exacerbate illness in the physical body and can increase emotional and spiritual distress (Box 14-7: Diversity Awareness). The basic goal behind the various modalities of **energy therapy** is to release blockages of energy flow, stimulate deficient life energy, and rebalance life energy.

Box 14-7

Diversity Awareness

Hot and Cold Diseases

- Hispanic culture considers disease causation as an imbalance between hot and cold. Specific diseases are classified by their causation, and the treatments (food, home remedies, and medications) used to ameliorate disease are generally temperature opposites; for example, a cold treatment is used for a hot disease. Some examples of hot diseases are constipation, diarrhea, fever, pregnancy, ulcers, and rashes. Examples of cold diseases include arthritis, a cold, indigestion, menstrual cramps, stomachaches, and muscle spasms.

- Hispanic use of complementary and alternative therapies is substantial; these therapies are often used to support chronic conditions. Diabetes is a hot disease. Hypertension, which is considered to be caused by anger, fear, nervousness, and thick blood, is a hot disease. It is treated by the cold treatments of lemon juice and various teas. Asthma is a cold disease, treated by traditional herbal mixtures and by massage. Home treatments

traditionally complement traditional therapies and include cactus, aloe vera, and bitter gourd. If home treatments, which are generally initiated by an influential female in the home, are not successful, family and friends are consulted for advice. A spiritual leader (curanderismo) may also be consulted to perform a healing ritual for an especially recalcitrant problem. If this treatment fails to resolve the problem, an allopathic physician may be consulted.

- Because there is potential for drug interactions between allopathic medicines and the traditional medicines of the Hispanic population, it is especially important that allopathic providers understand the home treatments that this population is using. One way to ease the assessment of the use of home treatments is with an open mind and with acceptance of folk practices.

Acupuncture

Acupuncture manipulates life energy, referred to as **chi** or qi in some cultures, by stimulating precisely mapped points on the skin surface (Box 14-8: Research for Evidence-Based Practice). The points overlie the channels, called **meridians,** through which chi travels. The channels are named for the organs they affect, such as the lung meridian, heart meridian, and kidney meridian. Acupuncture may be used to diagnose disharmony; the points become tender to palpation in the **presence** of a disturbance in energy flow. The acupuncture points act as valves in the meridian system. When the points are stimulated, acupuncture acts as a treatment modality to correct disturbances in flow. When stimulated, the valve may open to release blocked or excess chi or close to allow chi to collect if chi is deficient. Stimulation of the points may be accomplished in several ways: by inserting fine needles into the points, by electrostimulation, by laser,

by light stimulation, and by burning herbs on or over the points to increase point stimulation, a technique called **moxibustion.** Acupuncture is one of the oldest healing practices in the world. Good evidence exists for the efficacy of acupuncture in a variety of realms, and the cost of treatment is often covered by insurance providers.

Box 14-8

Research for Evidenced-Based Practice

A meta-analysis of acupuncture's effectiveness as well as advances in the understanding of acupuncture's physiological action have led to the acceptance and broader use for this modality and new research directions (MacPherson et al., 2016). Acupuncture efficacy has been demonstrated in pain control and nausea suppression. In a melding of new technologies with this ancient tradition, acupuncture neuroimaging research has not only identified a novel brain-based marker for clinical pain perception but has also demonstrated brain image changes due to acupuncture therapy (MacPherson et al., 2016). Patients with fibromyalgia treated with acupuncture showed elevation of the level of a brain marker that correlates with pain intensity that normalized after treatment; positron emission tomography detected an increase of mu-opioid receptor–binding potential in multiple brain regions that correlated with reported relief of fibromyalgia pain.

Another study used functional magnetic resonance imaging to demonstrate a return to normal mapping after acupuncture treatment of carpal tunnel syndrome that correlated with subjective and objective symptom relief. This and other research has led to the development of clinical guidelines, health policy, and reimbursement practices for acupuncture therapies (MacPherson et al., 2016).

Acupressure is a form of acupuncture, where the meridian points

are stimulated with pressing, rubbing, squeezing, and stretching movements. The technique is taught in some massage schools because it is often used along with massage to move and balance the body's energies. **Shiatsu** uses a sequence of rhythmic pressure on acupressure meridians. A systematic review revealed that auricular point acupressure is a promising treatment for chronic pain management (Lin et al., 2015; Zhao et al., 2015).

Touch Therapies

In **touch therapies,** such as therapeutic touch, healing touch, and reiki, practitioners use their hands to direct life energies drawn from the environment to the individual in an effort to restore balance and harmony within the human energy system (Figure 14-2). **Reiki** comes from Japanese tradition and requires training by a reiki master. In addition to teaching the hand placements and symbolic gestures used in reiki, the master attunes the student (Box 14-9: Innovative Practice). **Attunement** opens the energy channel, enabling the student to bring universal energy through the body and to the recipient. Reiki is a form of energy therapy and has been evaluated in several clinical trials for treatment of anxiety and improvement of well-being in people undergoing cancer treatments (Fleisher et al., 2014). During these therapies the hands can be placed directly on the person's body or at a distance from the body.
