FIGURE 14-2 The assessment phase of therapeutic touch. The practitioner is attempting to sense disturbances or imbalances in the person's energy field.

Box 14-9

Innovative Practice

Inclusion of alternative and complementary practices is a challenge in an acute care hospital. At Brigham and Women's Hospital (BWH) in Boston, Massachusetts, an integrative care program, including a reiki volunteer program, has helped to provide a means for integrating healing practices for both nurses and patients (Hahn et al., 2014). BWH has the largest reiki volunteer program in the country, with 60 volunteers who have provided more than 35,000 treatments in the past 5 years. One of the authors (Hahn et al., 2014) noted "many times, patients become so relaxed they fall asleep. Nurses also request Reiki for themselves and staff on their unit." The team also offers music therapy, **pet therapy,** and meditation.

To increase the availability of these therapies, educational offerings are available on the internal television program channel. Staff reiki

sessions were used to help caregivers deal with the stress resulting from caring for victims of the 2013 Boston Marathon bombing. Volunteers provided reiki to 289 staff members who tended those wounded by the bombing.

From Hahn, J., Reilly, P., & Buchanan, T. (2014). Development of a hospital reiki training program: Training volunteers to provide reiki to patients, families, and staff in the acute care setting. *Dimensions of Critical Care Nursing, 33*(1), 15–21.

Therapeutic touch was conceptualized by nursing theorist Martha Rogers. She felt humans are composed of energy fields that interact with the energy fields of their environments (Phillips, 2015). Therapeutic touch practice comprises three essential elements. The first element is centering by the practitioner. **Centering** is a process of becoming calm, present in the moment, and connected with the individual being treated, allowing the practitioner to give the person undivided attention (Hover-Kramer, 2011). The centered practitioner is able to let go of personal feelings and emotions and is more open to inner perceptions. During assessment, the second element, the practitioner's hands move over the individual's body at a height of approximately 3 inches above the skin in an attempt to sense disturbances or imbalances in the person's energy field. The final element is a series of techniques to change the patterns in the human energy field, unruffling, to direct energy to the person to replenish depleted energy, modulation, and to balance or redistribute the individual's energies. **Healing touch** is similar to therapeutic touch but adds full-body techniques for moving energy and disorder-specific energetic interventions to the modulation phase of therapeutic touch (Hover-Kramer, 2011).

Jin Shin Jyutsu uses fingertips pressed on specific healing point combinations to balance energy along specific pathways. **Polarity therapy** is a combination of energy work, caring intention, movement exercises, and dietary regimens and is aimed at clearing energy blockages and building health (American Polarity Therapy Association, 2015). Many practitioners use magnets or magnet therapy to control magnetic fields around many body systems to aid in healing

and in the functioning of the systems.

Other Energy Modalities

Although the basis for many religious faiths, **prayer** focuses on the subtle energy life force known by different names. Prayer has different meanings to different people. A prayer may be a request for divine intervention, a type of meditation, or a form of intentionality that is useful in healing. Praying for others may be a form of **distant healing.** Although a recent meta-analysis (Radin et al., 2015) of high-quality experiments failed to show reliable effects, many who practice energy work believe that their efforts are effective over long distances. One method of participating in distance healing is the healing circle. The members of the healing circle join hands. Each member sends healing energy to his or her neighbor on the right until the energy is flowing around the circle. When the energy is flowing readily, each member of the group focuses the energy on one group member, who acts to send the energy to someone that person knows who is in need of healing. Each member of the circle may, in turn, receive energy from the group and send it to an individual in need of healing.

Music therapy uses a variety of methods in a therapeutic relationship to address physical, emotional, cognitive, and social needs of individuals. Music influences the limbic system, the area of the brain involved with emotions and feelings. Music is a form of sound energy, and this energy can be relaxing or stimulating, and has been used to decrease pain, depression, and disability. Dependent on the person and the mood desired, all forms of music can be used. In a randomized controlled trial in an ICU setting, harp music significantly decreased pain perception by 27% but did not significantly affect vital signs (Chiasson et al., 2013). Music has been successfully used to reduce distress in people with dementia (Mitchell & Agnelli, 2015).

Two-thirds of US households have at least one pet; nearly half of older Americans own a pet, but research on the therapeutic benefit of pets has been limited or not well designed. Cherniak and Cherniak (2014) provided an overview of international research findings that indicate reported benefits to older participants in the management of

agitation, some benefit with regard to the level of depression, the degree of loneliness, and a variety of physical activity benefits. Only one study demonstrated that older people with a pet may be more likely to fall or have an economic burden in caring for them. Cherniak and Cherniak (2014) conclude there is a need for more well-conducted research.

Nursing Presence

Nurses have the potential to alleviate suffering and improve health care outcomes through their **therapeutic presence** (Carlson & Lowe, 2013; Ross, 2015). By connecting deeply with individuals and their families, nurses are in a unique position to facilitate their journey toward recovery or a peaceful death. When using **nursing presence** as a holistic intervention and establishing a therapeutic relationship, nurses are fulfilling the definition of nursing as an art and a science. Aiken and colleagues (Shang et al., 2013) at the University of Pennsylvania have provided a plethora of evidence about positive outcomes, lower mortality and morbidity, decreased readmission rates, and improved patient and nurse satisfaction scores when nurses are able to be present in meaningful ways.

Holistic health involves knowing the physical self, the emotional self, the mental self, and the spiritual self, seeking a comfortable balance among these aspects of being (Table 14-4), and knowing what changes need to be made to achieve this balance (AHNA, 2012c). This knowledge is vital to both the nurse attempting holistic practice and the individual interested in pursuing holistic health.

TABLE 14-4

Being There Versus Being With

The Nurse Who Is There	The Nurse Who
Is attentive	Is available with whole self
Is task oriented	Enters the person's world
Does the right thing	Becomes vulnerable
Fulfills a role	Is present as a whole person
Assists with coping	Alleviates suffering
Provides security	Enables growth

The *Wellness Quiz* can assist both nurses and individuals in the exploration of self that begins the process of self-care (Box 14-10).

Box 14-10

Wellness Quiz

- Do you wake up with enthusiasm for the day ahead?
- Do you have the high energy you need to do what you want?
- Do you laugh easily and often, especially at yourself?
- Do you confidently find solutions for the challenges in your life?
- Do you feel valued and appreciated?
- Do you appreciate others and let them know it?
- Do you have a circle of warm, caring friends?
- Do the choices you make every day get you what you want?

If you answered "no" to any of these questions, congratulations! You have identified areas in your life that you may want to change. This can be valuable information.

From Caton, S. (Ed.). (2003). *Wellness from within: The first step.* Anaheim, CA: American Holistic Health Association.

When self-knowledge is gained, one or more of the holistic health strategies mentioned in this chapter, as well as emerging therapies, can be useful in helping people achieve optimal wellness. Every person is a whole, unique being; therefore each person needs to explore the possible strategies and individually decide which modalities are the best methods to achieve an improved state of wellness. People beginning this self-exploration and the practice of holistic health strategies may find that the practice changes their lives. Using presence and giving the gift of self enhances personal growth in the caregiver.

Safety and Effectiveness

Most CAM therapies lack a strong scientific evidence base, as many have not been studied with rigorous, well-designed clinical trials. The National Institutes of Health is sponsoring research to fill the knowledge gap and build this foundation for safety, efficacy, and suitability for specific conditions.

The US FDA regulates dietary supplements, but the regulations are less strict than those for prescription or over-the-counter medications. For example, safety and efficacy do not have to be proven before a product is marketed, although once the product is on the market, the FDA does monitor label claims and inserts.

Most CAM providers are not credentialed in a standardized national system, so credentialing regulations and standards differ nationally (NCCIH, 2015i). Some require training, testing, and continuing education, but most do not. Many practitioners belong to professional organizations that establish the requirements for their profession (Box 14-11).

Box 14-11

More Website Information

- The NCCIH webpages at http://nccih.nih.gov/health/provide further guidance on how to be an informed consumer, how to obtain information for the health care professional, and how to find and select a CAM practitioner.

- The NCCIH Clearinghouse (http://nccih.nih.gov) provides information on CAM and NCCIH, including publications and searches of federal databases of scientific and medical literature. The NCCIH Clearinghouse does not provide medical advice, treatment recommendations, or referrals to practitioners. The Office of Dietary Supplements (https://ods.od.nih.gov) seeks to strengthen knowledge and understanding of dietary supplements by evaluating scientific information, supporting research, sharing research results, and educating the public. Its resources include publications (such as *Dietary Supplements: What You Need to Know*),

fact sheets on a variety of specific supplement ingredients (such as vitamin D and black cohosh), and the *PubMed Dietary Supplement Subset*.

- PubMed (http://www.ncbi.nlm.nih.gov/sites/entrez) is a service of the US National Library of Medicine (2016) and contains publication information and (in most cases) brief summaries of articles from scientific and medical journals.

- The National Library of Medicine's MedlinePlus provides resources that help answer health questions. MedlinePlus brings together authoritative information from the National Institutes of Health as well as other government agencies and health-related organizations (see http://www.medlineplus.gov).

- The National Guideline Clearinghouse (http://www.guideline.gov) provides evidence-based clinical practice guidelines and includes the use of CAM practices.

- Institute of Medicine *Clinical Practice Guidelines We Can Trust* (http://iom.nationalacademies.org/Reports/2011/Clinical-Practice-Guidelines-We-Can-Trust.aspx).

It is imperative that nurses and other health care professionals have knowledge of CAM practices, safety, and guidelines for use to inform and protect users. Many medical and nursing schools now include alternative/complementary therapies in their curricula. To help ensure client safety, practitioners and users should review the following principles:

- Carefully select CAM practitioners with appropriate training and experience. The US National Library of Medicine (2016), a division of the National Institutes of Health, provides a directory of providers, services, and facilities (https://www.nlm.nih.gov/medlineplus/directories.html).
- Take time to research and understand the treatment and its effectiveness.

- Be aware of scams and fraudulent claims.
- Know the costs and if the treatment is covered by insurance.
- Quality is not always regulated for dietary supplements, and they may have side effects or react dangerously with other medications and supplements. In addition, they may not have been tested on children or pregnant women, so check labels with care.
- Some energy treatments may have side effects and cause inflammation that can affect other conditions and may not have been tested on children or pregnant women.
- Always inform the care providers and both traditional and holistic practitioners about the use of CAM therapies.

The American Nurses Association recognizes holistic nursing as an official nursing specialty with its own defined scope and standards of practice. The AHNA (2015a) defines holistic nursing as "all nursing that has healing the whole person as its goal and integrates **complementary and alternative medicine** (CAM) approaches into clinical practice." According to the AHNA, a holistic nurse:

- Is a legally licensed nurse who takes a mind-body-spirit-emotion approach to the practice of nursing
- Serves as a bridge between conventional healing and complementary and alternative healing practices, and is trained in both health care models
- Works in a variety of settings—from hospitals to universities to private practice
- May specialize in one or more modalities (or methods of healing), such as acupuncture, chiropractic, or energetic healing (AHNA, 2015a)

Let us return to Ms. Gonzalez and review what is known about her CAM options and their safety and efficacy for her. To review, lung cancer has recently been diagnosed in Ms. Gonzalez. She has never smoked and has never taken prescription medications. Her family and friends have counseled her about various CAM modalities. She is also scheduled to receive traditional allopathic lung cancer treatment.

Teaching Points for Ms. Gonzalez:

- Aspirin prolongs bleeding, so she should stop taking aspirin 5 days before surgery.
- Coenzyme Q_{10} is claimed to have three main possible benefits: possible anticancer effect; protect the heart from toxic damage caused by chemotherapy drugs; and counteract chronic fatigue. Evidence to support coenzyme Q_{10} working as an anticancer agent is lacking (Rottorf et al., 2014).
- Amygdalin/laetrile has been banned in the United States (Stapf et al., 2015).
- Milk thistle may have protective effects for her liver if she needs chemotherapy.
- Green tea has antioxidant properties and may counteract her chemotherapy, and uses oxidation to work on cancer cells.
- Kava kava may have an effect or it may have a placebo effect, but it may interact with anesthetic agents, and thus its use must be stopped 1 week before her surgery.
- Yoga, reiki, and acupuncture have demonstrated positive outcomes, and she should be referred to licensed practitioners.
- A careful assessment of her dietary supplements is necessary, as many inhibit therapies, including radiation therapy. Antioxidants are useful for prevention of cancer, but with some cancer treatments, they are counterproductive (Shang et al., 2013).

Now see if you can answer these questions.

- What is the difference between reiki and massage?
- What occurs in a usual visit for acupuncture or a reiki session?
- How do these therapies work?
- Are these therapies evidence-based?
- What is the best understanding of the biological and physiological mechanisms for these therapies?
- What is the best understanding of the safety of these therapies?
- Which therapies are covered by her insurance?

- Would Ms. Gonzalez's therapies be considered complementary, alternative, or integrative?

Case Study

Use of Therapeutic Touch: David P.

David P., an 82-year-old white man, came to the clinic reporting neck pain and stiffness of approximately 4 months' duration. He was previously treated with ibuprofen (Motrin), acetaminophen, and oxycodone (Percocet) as well as with physical therapy. At the time of the initial clinic visit, David P. was still taking ibuprofen but had stopped taking oxycodone because the pain "isn't bad enough to take drugs [narcotics]." He rated his neck pain as 5 on a scale of 1 to 10. Neck range of motion had increased, but he had problems when driving. David P. lives next to a very busy street and did not feel that he could turn his neck well enough to see the traffic coming. He was afraid to pull out into the street. His daughter had driven him to the clinic. She said, "Pop is still in pain. He has little interest in doing anything. He walks like an old man, and he can't work in his garden because of the pain." The goal of treatment for David P. is pain relief and increased range of motion.

Reflective Questions

- What holistic health strategies might be used to relieve David's pain and to help him increase his range of motion?
- After the treatment goals have been reached, what holistic health strategies would you recommend to assist David P. in maintaining and improving his health?

Therapeutic touch was offered to David P. Although he was skeptical that this treatment would be effective, he agreed to treatment to please his daughter. Increased heat was noted in the neck and

shoulder areas. A 30-minute therapeutic touch treatment was performed, with special attention given to the neck and shoulder area. Immediately following the therapeutic touch, David P. rated his pain as 0 on a scale of 1 to 10 and reported that he “couldn't remember when he'd been so relaxed”; and the excess heat had dissipated. David P. was also given some simple yoga exercises for the neck and advised to perform the exercises twice a day, five gentle repetitions each time. David P. was seen in the clinic a total of eight times for therapeutic touch and was given increasingly difficult yoga stretches for the neck and shoulders. His pain rating at the end of treatment remained at 0 on the 1 to 10 scale. He had stopped taking ibuprofen, saying, “I don't need it anymore.” His neck range of motion had increased, and he was driving and working in his garden again. He continues his yoga stretches and has started performing daily qigong exercises.

Care Plan

Use of Therapeutic Touch: David P.

***NURSING DIAGNOSIS: Disturbed energy field disturbance related to slowing or blocking of energy flow secondary to repetitive motion injury**

Defining Characteristics

- Perceptions of changes in patterns of energy flow, such as:
- Temperature change: warmth, coolness
- Visual changes: image, color
- Disruption of the field: vacant, hole, spike, bulge
- Movement: wave, spike, tingling, dense, flowing
- Sounds: tone, words

Related Factors

- Pathophysiological: illness, injury
- Treatment-related: immobility, perioperative experience, labor and delivery
- Situational: pain, fear, anxiety, grieving
- Maturational: age-related developmental difficulties or crises

Expected Outcomes

- The person will report increased sense of relaxation.
- The person will report decreased anxiety and tension.
- The person will demonstrate evidence of physical relaxation (e.g., decreased blood pressure, pulse, respiratory rate, and muscle tension).
- The person will report an increased sense of well-being.

Interventions

- Provide privacy if possible.
- Explain energy therapy (therapeutic touch, reiki, healing touch) and obtain permission to treat the person.
- Position the person comfortably.
- Become quiet and still (centered) and bring the focus to the person.
- Assess (scan) the energy field for openness and flow.
- Clear the exterior energy field by combing through the field from

head to toe (unruffling).

- Move the palms of the hands toward the person, 2 to 4 inches over the person's body, from head to feet in a smooth, light movement.
- Sense the cues to energy imbalance (i.e., warmth, coolness, tightness, heaviness, tingling, emptiness).
- Focus on perceived areas of imbalance to repattern the energy flow.
- Reassess and smooth the exterior energy field, ensuring that the energy flow is open in the feet.
- Gently stop the treatment and allow the person time to rest.
- Encourage the person to discuss the experience.

---

*NANDA Nursing Diagnoses—Herdman, T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Holistic health strategies are designed to view the individual as a biopsychosocial-spiritual whole being. Many holistic health strategies have been practiced in other cultures for thousands of years; some began as religious practices. Many of these strategies can be used to help nurses and those they serve reach the *Healthy People 2020* goals. However, high-quality evidence-based research is lacking, although there is an increased awareness of the practices and more studies are being done. Holistic health practitioner and many consumers are convinced that these practices help promote and maintain health or cure a variety of health conditions. Believing is sometimes therapy in itself. The placebo effect is not well understood but has a strong influence on the results of any research study, whether in conventional or complementary medicine.

Every person is a unique, individual being; therefore some exploration of self, the various strategies, and the practitioner will be necessary before it is determined which strategy is the right fit for each individual. Nurses must understand holistic health strategies because individuals are using them in increasing numbers, and they are evolving and expanding into new methods, such as hot yoga, where the therapy is conducted in a heated room at a temperature above 90° F. Nurses who begin to practice holistic interventions may find them a useful and exciting adjunct to their nursing practice and their personal lives.

Overview of Growth and Development Framework

Elizabeth Connelly Kudzma

OBJECTIVES

After completing this chapter, the reader will be able to:

- Define the terms growth, development, and maturation.
- List factors that influence growth in an individual.
- Explain the importance of growth and development theory as a framework for assessing and promoting health.
- Outline Erikson's theory of psychosocial development.
- Differentiate Piaget's and Vygotsky's theories of cognitive development.
- Compare Kohlberg's and Gilligan's theories of cognitive moral development.
- Analyze individual growth and development, distinguishing normal and abnormal processes.

KEY TERMS

Cephalocaudal

Denver Developmental Screening Test

Development

Developmental patterns

Differentiation

Erikson's theory of psychosocial development
Gilligan's theory of moral development
Growth
Growth charts
Growth patterns
Kohlberg's theory of moral development
Learning
Maturation
Piaget's theory of cognitive development
Proximodistal
Scaffolding
Vygotsky's theory of cognitive development
Zone of proximal development

Think About It

Vaccine Issues and Controversies

A 4½-year-old child begins to scream as the nurse approaches with her "kindergarten shots." The mother tries to comfort her child, as she turns anxiously to the nurse and states, "I've heard vaccinations can be dangerous. No wonder she's frightened. Are they really necessary?"

- What influence might the mother's anxiety have on the child's behavior?
- What approaches and information can the nurse have for the mother?
- What resources might the mother use to review recommendations for childhood vaccinations?

- What approaches can the nurse take to gain the child's cooperation?

Unit 4 introduces growth and development as a framework for health assessment and promotion throughout the life span. Understanding human growth and development facilitates nursing assessment of health knowledge and behavior. Furthermore, health education is more effective when the nurse acknowledges and incorporates growth and developmental needs, as well as the individual's prior understanding of and beliefs about health and health-related concepts.

Growth and development theory is incorporated in many places in *Healthy People 2020*. Throughout Unit 4, specific topics and objectives from *Healthy People 2020* will be examined in chapters appropriate to the age and individual developmental level in the life span under discussion. Although these objectives will serve as guides for the promotion of health care at each level, the topic "access to health services" crosses all levels and the entire life span. The first four objectives that increase access to health services for all people and families include increasing the proportion of individuals with health insurance; increasing the proportion of insured individuals with coverage for clinical preventive services; increasing the proportion of individuals with a usual primary care provider; and increasing the number of practicing primary care providers, including nurse practitioners (US Department of Health and Human Services, 2016). Without access to health services, health promotion cannot occur and a person has difficulty achieving and maintaining health. This chapter focuses on the study of health promotion at individual developmental levels by exploring basic concepts foundational to growth and development, as well as providing an overview of representative theories of development. Each of the following nine chapters provides health-assessment and health-promotion strategies appropriate for selected age groups across the life span. The age groups described are the childbearing period, infant, toddler, preschool child, school-age child, adolescent, young adult, middle-aged adult, and older adult (Table 15-1).

TABLE 15-1

GROWTH AND DEVELOPMENT
Developmental Periods at a Glance

Period	Age	Characteristics
Infant	Birth to 12 months	Fully dependent on others for basic needs
		Ends as infant begins to explore environment, walks alone, and develops basic communication skills
Toddler	12 months to 3 yr	Motor development progresses significantly
		Child achieves a degree of physical and emotional autonomy while maintaining a close identity with the primary family unit
Preschool child	3–5 yr	Child has increased interest in and involvement with peers and may have social interactions with many people
School-age child	5–12 yr	Marked by entry to elementary school; interests turn away from family toward peers
Adolescent	12–18 yr	Period of transition, adjustment, and personal exploration; ends when adolescent demonstrates readiness to assume full adult responsibilities of financial, emotional, and social independence
Young adult	18–35 yr	Establishing an occupation or career, finding and learning how to live with a partner, and starting and rearing a family
Middle-aged adult	35–65 yr	Being established in a marriage, an occupation or career, and a community; may continue to be a time of transition; adjusts to physiological changes of middle age
Older adult	>65 yr	May be a time of continued involvement in work and active socializing; adjusts to decreased physical strength and health; retirement; reduced income; decreasing independence; and deaths of spouses, friends, and self

Overview of Growth and Development

Fuller understanding of growth and development has continued to expand with advances in science. Currently, the genomic era is intersecting with the digital age, and nursing educators are racing to integrate genomic content (Read & Ward, 2016). The contribution of genomic knowledge to growth and development is huge, and there is an explosion of findings on genetic and long-term impacts of early development on later health and health-related behaviors.

Individuals continue to evolve throughout the life span, and developmental transitions occur beyond childhood and adolescence, extending into the early, middle, and later adult years. Aging adults are receiving increased attention as the average life expectancy increases, and the adult population older than 85 years has become the fastest growing age group, providing new challenges for health protection and promotion.

Growth

Growth refers to a quantifiable change in structure size. In the body this change increases the number and/or size of the cells, resulting in an increase in the size and weight of the whole, or any of its parts. During childhood, physical changes in height, weight, and head circumference, or growth parameters, are measured and recorded regularly. Growth refers to both the obvious changes in the whole individual and to the increases (and as we age, decreases) in the size of specific organs and systems. The health history and physical assessment of an individual should include all body systems and should emphasize systems undergoing the most change. Table 15-2 outlines growth as it occurs throughout the body systems and life span. The growth of some systems, such as the skeletal and muscular systems, is more influenced by sex, whereas the growth of other systems, such as the nervous and respiratory systems, is less dependent on sex. Growth changes that occur in young, middle-aged,

and older adults should be noted. Thinking of growth only as it applies to infants, children, and adolescents misses important changes that occur from conception and throughout all the stages of adulthood.

TABLE 15-2

GROWTH AND DEVELOPMENT
Growth Changes Throughout the Life Cycle

Overview of Developmental Changes	Prenatal Period →	Infancy →	Childhood →	Puberty and Adolescence →	Adulthood →	Middle Age →
Heart and Circulatory System						
Action of heart and circulatory system is under the control of autonomic nervous system. Throughout life cardiac rate is responsive to organ needs and emotional states (fear, anxiety, tension, depression)	Heart formed and begins to beat about third week	Heart grows somewhat more slowly than rest of body (weight doubled by 1 yr, body weight triples). Grows steadily during childhood. With birth, considerable change in paths and relative volumes of blood flow, reflected in loss of certain fetal structures and changes in heart and major vessels		At puberty, heart takes part in rapid growth, reaching mature size with rest of body	Heart weight remains relat after age 25 yr (only organ prostate that does not decr with age). Capacity to incr strength of beat during ph diminished with aging. Ca lessens with age, whereas energy is more than in you	
	Heart rate high, ≈150 beats/min	Heart rate falls steadily throughout childhood			At maturity, women have pulse rate than men, 65 bea temperature remains static than boys'); men maintain in maturity (slightly lower temperature than women)	
		130 beats/min	70–80 beats/min	60 beats/min in adolescence, rate differs with sex		
		Heart rate more variable during childhood—regular				
		Not until middle childhood does peripheral blood picture become same as adult				
Urinary System						
Parallels growth as a whole. Proportion of	Young fetus is approximately 90% water. Urinary system	Newborn is approximately 70% water. Urinary	Composition of urine in healthy child (after age 2 yr) changes very little as child matures; thus renal function		Adult is approximately 58' Glomerular filtration rate approximately 47% from a 90 yr	

body water and solids follows pattern related to growth—tendency for human organism to dry out as life progresses. Function of kidneys, with other organ systems, is to help in regulation of internal environment of body	begins in first month	system does not complete full development until end of first year. All renal units immature at birth; thus fluid and electrolyte imbalance occurs readily. Kidney function adequate at birth if not subjected to undue stress	and urinalysis can be used as monitor of well-being	
Digestive System				
As a whole, grows as total body grows, although evidence suggests that various parts of gastrointestinal system undergo separate periods of growth, maturity, and senescence	Before birth nutrients are supplied through placental circulation; digestion and absorption do not occur in gastrointestinal tract	Stomach size increases rapidly in first few months, then grows steadily throughout childhood		All actions of gastrointesti intake, digestion, absorptic not only respond to physic but from birth to old age a to tensions and anxiety
			Spurt of growth at puberty	
		Digestive apparatus immature at birth (food passes through rapidly, reverse peristalsis common). Acidity of gastric juices varies over life span; low during infancy, rises during childhood, plateaus approximately age 10 yr, rises during puberty. Free gastric acid (HCl) more marked in boys		Data suggest generalized a entire gastrointestinal tract advancing age. Nutritional according to individual va decreasing metabolism—t intestine may become imp decrease with senescence (diminished taste)
	Salivary glands small at birth	Increase rapidly during first 3 months; reach relative adult proportions by age 2 yr		
Special Senses				
Most are well developed at birth, although their association with higher centers comes	Begin very early in embryonic development—3–6 wk	Sense of touch is developed first, then hearing and vision. Vision: infant c simple differences in shape but not complex patterns (greater proportion before birth); various dimensions of vision develop at various ages, eye m at mature level in first year, fusion begins at 9 months until 6 yr; refractive changes over life cycle—hyperopia increases until eyeball reaches adult si reverses trend toward emmetropia; postpubertal years—toward myopia u when myopia decreases and hyperopia increases		

about gradually during early life and diminishes with advancing age						
Adipose Tissue						
Although adipose tissue differs greatly among individuals, an overall lifetime pattern exists. Fat accumulation differs greatly with body build and constitution. Relationship between caloric intake, amount of exercise, and utilization or accumulation of fat is not yet fully understood but is the basis of much interrelated research	Accumulates rapidly before birth; peaks at seventh gestational month. Premature infant may look wrinkled and scrawny because of lack of adipose tissue	Increases rapidly during first 6 months	Decreases from first to seventh year in both sexes	Begins to increase slowly to puberty. Fat ~~begins to~~ accumulate slowly and continues to accumulate uninterrupted in girls, producing feminine curves, and accounts for much of weight gain	Some girls become slim after full maturation; ~~many~~ maintain approximately the same amount of adipose tissue as at puberty	Typically, both sexes tend to ~~gain~~ weight in their 50s and 60s but do not maintain the same body contours of earlier years at same weight (increased deposit on abdomen and hips)
		Sex differences are not noted in body shape of prepubescent children		Deposition of fat differs in body—amount decreases sharply at time of maximal growth spurt (increased weight caused by increase in muscle mass and bones)	After full maturation, fat accumulation begins	
Lymphoid Tissue						
Lymphoid tissue is scattered widely throughout the body and includes lymph nodes, tonsils, adenoids,	Begins during last month of uterine life—crosses placenta at levels equal to mother's and remains for several months	Grows most rapidly during infancy and childhood, reaching maximal size a few years before puberty; parallels development of immunity		Atrophies and is smaller in volume at full maturity than during childhood		

thymus, spleen, and lymphocytes of blood; follows unique pattern of growth, rapid in infancy and begins to atrophy at puberty	after delivery					
		Increased incidence of disease with increasing age of child				
Respiratory System						
Growth parallels that of total body. Respiratory apparatus is a highly-organized system of organs under nervous system and hormonal regulation, which functions in coordination with rest of body. Sex difference in gas exchange becomes apparent during puberty	Before birth, air sacs do not contain air; oxygen is supplied through maternal circulation	When umbilical cord is cut, infant must use own breathing apparatus—breathing irregular at first, both in rate and in depth—fast in infancy and gradually slowing through childhood until maturity is reached			No sex difference in respir any time of life	
						Basal meta declines (r men than i
		Respiratory exchange gradually becomes more efficient as life advances. A of air inhaled with each breath increases as lung size expands with genera Vital capacity and maximal breathing capacity rise gradually in both sexe more in boys during puberty; adult men have more efficient respiratory e capable of greater feats of muscular exertion without exhaustion than wo				
Skeletal System						
Bone growth passes through successive stages of development from connective tissue to cartilage to	Follows cephalocaudal law of development; 70% of head growth before birth; bones of hands and wrist laid		Reserved during growth spurt		Maximal height in early 20s to 30s	Gradual d onset of se

osseous tissue; completion of calcification indicates end of growing period and is thus a useful measure of growth rate and physiological maturity. Most growth ceases during adolescence	down in cartilage					
		After first year, legs grow fastest, 66% of total increase in height; the longer puberty is delayed, the greater the leg length				Thinning c disks begi years; mos decade
		Trunk fastest growing, 60% of total increase		Length of trunk and depth of chest reach peak growth		
		At birth, shafts of metacarpals are ossified (and visible by radiography); carpal bones begin to ossify	Growth of both sexes is nearly even until onset of puberty in girls first (≈10 yr). Boys begin ≈2 yr later, but growth is markedly greater. Peak in height comes before peak in weight			Spinal colu (osteoporo thinning v shortening long extre reversal of proportior
Muscle System						
Number of striated muscle fibers is roughly the same in all humans. Tremendous difference in size, not only from fetus to adult but also among adults, is caused by ability of individual muscle fibers to increase in size	Muscle formation begins early, assuming final shape by end of second month	Increases rapidly during infancy but slowly during childhood		With onset of puberty, muscle strength is greater in boys (when muscle growth is stimulated by testosterone)	Muscle mass continues to i gradually—maximal stren early adulthood—then dec according to use and genet Will increase in bulk and s until onset of senescence	
			Growth in both sexes is same in childhood			
				Greatest increase begins in		

				puberty; muscle size precedes muscle strength in boys		
			Increase in muscle size means increasing strength in children; increase in skill is more intimately related to maturation of nervous system			
Nervous System						
Growth and maturation of central and peripheral nervous systems (brain, spinal cord, peripheral nerves, many sense organs) reflected by changing size of head	Growth very rapid during intrauterine development; head grows at greater rate than rest of body	In first year has all the brain cells, which will continue to increase in size; number and complexity of axons, dendrites, and synapses will continue to increase			Function continues with use	
		All neural tissues grow rapidly during infancy and early childhood		(No neural growth spurt at puberty)		
		Brain grows rapidly after birth, reaching 90% of total size by age 2 yr	By middle childhood almost reaches adult size	Slow increase to full maturity	Brain weight decreases with age	
	Segmented spinal nerves are mature, fully myelinated, and functioning at term (e.g., knee jerk), but acquisition of myelin in cortex, brainstem, and spinal cord is closely correlated with observed behavior (myelination of this tract follows cephalocaudal, proximodistal rules)					Taste less a discrimina advancing
		Equipment for sense of taste and smell present at birth and perhaps most acute at that time				Structural central ner result in in perception
Reproductive System						
Organs of reproductive system show little increase during early life but rapid development	Genital organs form during uterine life; uterus undergoes growth spurt before birth	Female sex organs well formed but not functioning at birth (but have full	Quiescent during childhood →	Maturation at puberty (menstruation) →		

just before and coincident with puberty. Maturation and fulfillment of reproductive functions of maturity (in female) are followed by involution in later years	(hormonal stimulation from mother)	quota of sensory nerves)				
		Uterus undergoes involution to half its birth weight	Regained size by age 10–11 yr →	Adult size at puberty →	Maximum increase with pregnancy →	
		In males, testes, as with ovaries, remain dormant and small, not even growing in proportion to rest of body (with sensory nerves)	Until puberty, interstitial cells of Leydig reappear and secrete testosterone, so testes and penis continue to increase in size; pubic hair appears			
	Mammary glands develop in both sexes during fetal life	Enlargement of breasts at birth (both sexes) →	Nonsecretory during childhood until puberty →	Development rapid →	Enlarge during pregnancy, developing alveoli →	
	Sex hormones: until puberty girls and boys produce male hormones (androgens) and fema (chiefly estrogens) in small and roughly equal amounts					
Integumentary System						
Includes skin and its appendages and adnexa (nails, hair, sebaceous glands, eccrine and apocrine sweat glands). Although all skin is similar, this organ shows considerable variability in different parts of body (and from individual to individual) and varies greatly during	Hair, skin, and sebaceous glands fully formed in utero	Skin contains all its adult structures at birth but immature in function	Matures slowly until puberty (children prone to rashes)	Rapid spurt in maturation of skin and all its structures		

life span						
	Lanugo begins to decrease before birth and continues regression for a few weeks postnatally →		Replaced by body hair, less extensive distribution; marked difference in type and distribution of hair at puberty →			
	Activity of sebaceous glands decreases after birth →			Increases rapidly at puberty (more prone to acne)		
Endocrine System						
Consists of a number of glandular structures scattered throughout body. Although small in size, their hormones influence all growth and development of whole organism	Immaturity of entire endocrine system puts infant at a disadvantage if required to adjust to wide fluctuations in concentration of water, electrolytes, glucose, and amino acids. All are interrelated, but each organ develops at its own rate: • Thyroid—increases in size from midfetal life to maturity; slightly larger in boys than girls; growth spurt at adolescence • Adrenals—after birth decrease in size and this continues throughout first year, increase again during childhood (but smaller than at birth); spurt at puberty, reaching maturity with rest of body; greater increase in male gonads and testes and female ovaries (endocrine glands as well as reproductive organs), follow genital type of growth pattern • Hypophysis, or pituitary gland—produces or stimulates hormones that influence growth • Parathyroid—produces hormones that maintain homeostasis of calcium and phosphorus • Islets of Langerhans—dispersed throughout pancreas; produce insulin and glucagon					With age, (in all endo functions

NOTE: This table indicates only general trends in growth and development; it is not all-inclusive. No distinct ages, absolute values, or ranges of normal variations are intended in this table.

Modified from a format originally developed in Sutterly, D. C., & Donneley, G. F. (1973). *Perspectives in human development: Nursing throughout the life cycle.* Philadelphia: J. B. Lippincott. Further modified from Papalia, D. E., & Feldman, R. D. (2011). *Experience human development* (12th ed.). New York: McGraw Hill. Physiological adaptations updated from McCance, K. L., Huether, S. E., Brashers, V. L., & Rote, N. S. (2014). *Pathophysiology: Biological basis for disease in adults and children*. St. Louis: Mosby.

Influences on an individual's potential for growth include genetic factors, prenatal and postnatal exposures, nutrition, and environmental factors (see the case study and care plan at the end of this chapter). Other influences include emotional health and traditional cultural practices that influence childrearing, lifestyle, and health care practices (Box 15-1: Diversity Awareness). Although much of the potential for growth is primarily determined by individual

genetics, health and environmental exposures influence the attainment of that potential (CDC, 2011a,b). The timing of contact with environmental hazards and stressors may determine to a great extent the amount and kind of effects of these influences. If a pregnant mother is exposed to a virus in utero (e.g., the Zika virus), the developing fetus is more vulnerable than either the mother or an older child, especially during the first trimester, when all organs systems are in a stage of rapid growth and development. Teens who fracture a limb at the bone's growth plate also have more difficulty healing than older teens and young adults who have completed their growth spurt.

Box 15-1

Diversity Awareness

Childhood Lead Poisoning and Latino Families

Whereas the United States has made tremendous progress in eliminating some of the more significant sources of lead (lead paint was banned in 1978; leaded gasoline was phased out in the early 1990s), lead poisoning remains a significant threat to today's children. Lead exposure results in behavior and learning problems, decreased intelligence, attention problems, lower academic achievement, impaired growth, poor eye-hand coordination, and hearing loss. The CDC (2014) now uses a reference level of 5 mcg/dL to identify children with lead exposure, and this reference value is lower than in past years. As a consequence, more children will likely be identified as having lead exposure. The National Safety Council emphasizes that lead poisoning is a totally preventable disease. During the past 2 decades, public health and provider efforts have resulted in a 90% decline in the overall number of children affected in the United States. The Flint, Michigan, water contamination crisis that started in April 2014 illustrates the importance of lead testing during childhood and prompt treatment of children who demonstrate high lead levels (Bosman & Smith, 2016).

However, there are more specific risks for Latino families. One-

third of the Latino population resides in Western states and is exposed to pesticides, fertilizers, and chemical residues contaminating the water. Food and culturally defined health practices pose additional risks of lead exposure to this population (CDC, 2011). Foods packaged or canned outside the United States (especially in Mexico or South America), foods cooked in, stored in, eaten from, or drunk from ceramic containers or pottery made outside the United States (especially in Mexico or South America), Mexican or South American raisins, and wrapped Mexican candies may all contain lead.

Empacho, a common Hispanic term for stomach or intestinal upset or obstruction, is often treated with a folk remedy that contains 70% to 90% lead. It is known by many names, including *alarcon, azarcon, coral, greta, liga, Maria Luisa,* and *rueda.* Another common Hispanic folk remedy containing lead is *pay looah.*

An often-overlooked risk is the use of warm, hot, or boiled tap water from contaminated pipes. Many Hispanics feel that heating the water removes contaminants, although any heat mobilizes the lead and makes it easier to absorb. This is also true of pottery that is heated by cooking in it, placing heated fluids in it, or heating it in a microwave oven. Although typical instruction pamphlets teach that tap water should be run for a full minute before it is consumed, they fail to state that the water consumed should come from the cold tap if it is to be consumed.

When screening for lead poisoning in Hispanic children, the nurse remembers to ask about the use of folk remedies, pottery, imported foods, and candies, as well as the use of boiled or hot tap water. In addition, the nurse encourages a diet with less fat, because lead is retained in fat, and a greater vitamin C, calcium, and iron intake, which reduces the amount of lead in the body.

Growth Patterns

Expected **growth patterns** exist for all people. Growth is not steady or uniform throughout life. The periods of extremely rapid growth—childbearing period, infancy, and adolescence—are contrasted with slower rates of growth during the toddler, preschool, and school-age periods. Infants typically double their birth weight by 6 months of age and triple their birth weight by 1 year of age. The well-known early adult "growth spurt" in height typically occurs early in adolescence for girls and later in adolescence for boys.

Different parts of the body increase in size at different rates. For example, during early life the head is the fastest growing section, followed by the trunk, and then the arms and legs. Newborns' heads account for one-quarter of their overall length, as opposed to adults' heads, which account for one-ninth of their overall height. The growth changes in proportions of body parts from infancy to adulthood are

demonstrated in Figure 15-1.

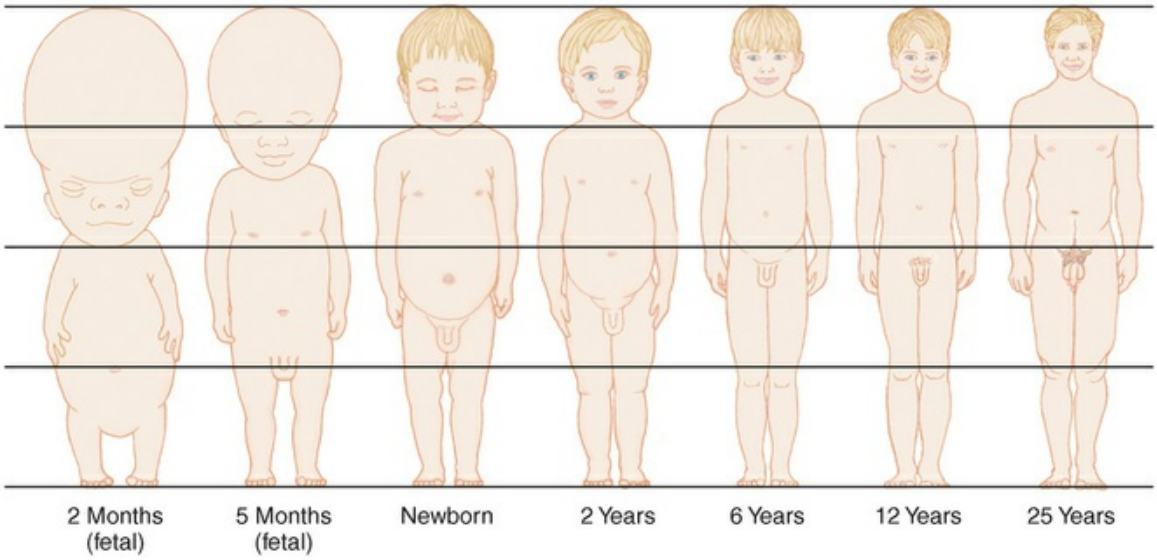

FIGURE 15-1 Changes in body proportions from birth to adulthood. (From McKinney, E. S., Smith Murray, S., James, S. R., & Ashwill, J. [2009]. *Maternal child nursing* [3rd ed.]. St Louis Saunders.)

Growth Charts

Growth is one of the most important indications of a child's overall health and well-being. Accurate growth assessment depends on precise measurement of growth parameters with proper equipment, correct and consistent techniques, careful plotting of measurements, and thoughtful interpretation of the data.

On the basis of input from an expert panel, the Centers for Disease Control and Prevention (CDC) recommended that health practitioners in the United States use the 2006 World Health Organization (WHO) international **growth charts** for children from birth to 24 months, and continue to use the revised 2000 CDC growth charts (including the body mass index [BMI] and the 3rd and 97th percentiles) for children aged 2 to 20 years. This recommendation was based on the fact that WHO growth charts were compiled from healthy breastfed infants living in optimal conditions and achieving the greatest potential of

growth possible, which was recognized as the desired standard against which to compare the growth of all other infants (CDC, 2010). In creating the WHO growth charts, researchers gathered data from six countries (Brazil, Ghana, India, Norway, Oman, and the United States) using longitudinal and cross-sectional methods (Mei & Grummer-Strawn, 2011). The exceptional strength of the WHO growth charts is that they are globally representative (Ziegler & Nelson, 2012). The CDC and the WHO growth charts both describe weight for age, length (or stature) for age, weight for length, and BMI for age, and include the 5th and 95th and the 3rd and 97th percentiles (CDC, 2010). The WHO and the CDC growth charts for each sex with percentile curves can be viewed at the CDC website: http://www.cdc.gov/growthcharts/. These charts have been used by pediatricians, nurses, and parents to compare infant, child, and adolescent growth since 1977.

When one is assessing growth data for use in the growth charts, it is important to remember that a single measurement taken at one point in time, although helpful in providing a baseline, does not allow the best assessment of a child's growth. Serial measurements plotted over time on a growth chart best reflect a child's pattern of growth. Slowed growth, plateaus, or decreases in height, weight, and head circumference, as well as rapid increases, raise questions for health care providers about the adequacy of a child's nutritional intake, disease states, neglect, or emotional problems. See Box 15-2: Research for Evidence-Based Practice on the use of the new growth charts and young children.

Box 15-2

Research for Evidence-Based Practice

Comparing the New Growth Charts: Prediction of Future Obesity From Childhood Weight Status

The CDC and WHO growth charts use the same indicators for

growth, and comparative studies have been done to indicate differences when each chart is used. These studies are critical to provide better support for public health prevention efforts addressing the increasing prevalence of childhood obesity (Mei & Grummer-Strawn, 2011).

From the beginning, it was recommended that when the WHO growth charts are used to screen individuals for abnormal or unhealthy growth that the narrower ranges of the 3rd and 97th percentiles should be used instead of the 5th and 95th percentiles respectively. This would identify fewer children as underweight as slower growth among breastfed infants is normal within the first 6 months.

Rapid weight gain during the first year of life is predictive of obesity in 2-year-olds to 3-year-olds, and there is need to promote parental awareness regarding the actual weight of their children (Vallejo et al., 2015). Maalouf-Manasseh and colleagues (2011) also reported that gaining weight more rapidly in the first year than directed by the WHO growth charts may be an early sign of later obesity.

Ziegler and Nelson (2012) observed in their comparative studies that the weight percentiles of the WHO growth charts were higher in the first 6 months and lower between 6 and 24 months when compared with the same age range CDC percentiles. Their conclusion was explained not only by their appreciating that breastfed infants grow somewhat slower than formula-fed infants but also by their realizing the attrition rate of low-weight-gaining breastfed infants that occurred when data were being compiled for the WHO growth charts.

Whereas the WHO growth charts may be used for national and international observations of malnutrition, it is imperative that additional data be obtained before the WHO standards can be applied for local public health interventions. The low weight of the WHO growth charts should not be used to misclassify a child as overweight or obese with the use of corrective interventions (Ziegler & Nelson, 2012).

Although the new WHO growth charts furnish health care providers and researchers with an improved tool to assess and track the growth of children from birth to 24 months of age, care must be taken not to misinterpret the results for each individual child. As indicated by the evidence presented, it is too early to use the WHO growth chart as the magic bullet of early identification of and intervention for future obesity in children during the first year of life. Mothers' underestimation of the weight of their own children was common in both overweight and children of normal weight (Vallejo et al., 2015). Continued investigation in this area is promising for planning of health care education to counter factors contributing to the child and later adult obesity epidemic.

From Maalouf-Manasseh, Z., Metallinos-Katsaras, E., & Dewey, K. G. (2011). Obesity in preschool children is more prevalent and identified at a younger age when WHO growth charts are used compared with CDC charts. *Journal of Nutrition*, *141*, 1154–1158; Mei, Z., & Grummer-Strawn, L. Concept of Development

Development refers to change and expansion of ability and advancement in skill from a lower to a more advanced capability. In contrast to growth, which is a quantitative or precisely measurable change, development is a qualitative change. Qualitative changes are more challenging to describe because they cannot be easily measured in precise units. Development has best been conceptualized as a process that can be assessed because it follows certain sequencing or patterns, although the timing of this advancement is individual.

Developmental Patterns

All individuals follow similar **developmental patterns**, with one stage of development building on and leading to the next. Early

development proceeds as follows:

- **Cephalocaudal**, from head to toe
- **Proximodistal**, from midline to periphery
- **Differentiation** follows a pattern: simple to complex, and general to specific

The following are examples of patterns of development:

- Cephalocaudal: Infants advance in neck and head control before controlling the movements of the extremities.
- Proximodistal: Infants' central nervous systems develop before peripheral nervous systems.
- Differentiation: Infants use a whole-hand grasp before learning the finer control of the pincer grasp, and they coo or babble before they speak.

Although the sequence of development is predictable, the exact timing of the sequencing depends on the individual. Individuals develop at their own rate, on their own schedule. For example, infants creep and crawl before they walk and their primary teeth erupt in a predictable sequence, but each will walk and develop primary teeth on an individual schedule. However, there are guidelines or parameters that assist parents and health care providers in assessing whether children are progressing in an acceptable developmental sequence within a reasonable time frame. Areas of assessment usually focus on personal and social, gross and fine motor, and language development. The **Denver Developmental Screening Test**, which was revised in 1992 (now known as Denver II), is a screening tool that assists health care providers in monitoring children's development in each of these areas from birth to 6 years of age.

Social expectations can influence developmental tasks with expectations that an individual achieve certain landmarks during each period of development. However, the age at which a child is expected to master certain developmental tasks is determined partly by cultural expectations. Some cultures are comfortable with breastfeeding their children well into childhood, whereas others expect the transition to self-feeding with a cup much earlier. When assessing a child's

abilities, nurses are aware that a child who has never been given the opportunity to learn or master a skill may be developmentally capable but fails when tested. For example, a child who is capable of learning colors or numbers can do so only if taught, just as the child who was breastfed well into childhood, never having been offered a cup, may well be developmentally capable of drinking from a cup but probably will fail in early attempts.

Development is closely interrelated with the concepts of both learning and maturation. **Learning** is the process of gaining specific knowledge or skills that result from exposure, experience, education, and evaluation. **Maturation** is an increase in competence and adaptability that reflects understandings in the complexity of a structure that makes it possible for that structure to begin to function or to function at a higher level. Maturation of a structure, system, or individual refers to the emergence of the genetic potential of that structure, system, or individual. Learning cannot occur unless the individual is mature enough to understand and control behavior. Children can be toilet trained only when their bodies have matured to the point of developing internal and external sphincter control. Earlier attempts will be frustrating for both the child and the parent.

Growth and development are complex, interrelated processes that are influenced by and, in turn, influence the health of an individual. The nurse who understands this relationship is aware of the need for age-specific health-assessment, health-protection, and health-promotion strategies (Box 15-3: Quality and Safety Scenario).

Box 15-3

Quality and Safety Scenario

Anticipatory Guidance

The nurse is often in a position to provide anticipatory guidance to parents, which involves teaching parents ways to handle a situation before it becomes an issue or problem. Knowledge of normal growth and development provides a foundation for this teaching. For

example, the toddler period is one of intense exploration of the environment, when locomotion is the major gross motor skill acquired. The nurse, knowing the number one cause of death in toddlers is accidents, provides the following teaching to the parents of a child who is entering the toddler period:

- Use a federally approved car restraint/car seat and check for proper installation and placement.
- Supervise a child closely near any source of water, including buckets, bathtubs, toilets, and especially swimming pools.
- Move pot handles toward the back of the stove and use the back burners whenever possible.
- Place toxic substances in a locked cabinet and have the poison control contact number easily accessible. Avoid the use of syrup of ipecac unless advised by a poison control representative to use it.
- Move a toddler from the crib to a bed.
- Provide barriers on open windows.
- Decrease water temperature to avoid scald burns from tap water.
- Avoid foods that pose a choking hazard such as nuts, hard candies, raisins, fresh carrots, whole grapes, chewing gum, hot dogs, and fish with bones.
- Guard against the toddler running into the street when walking and playing outside.

Theories of Life span Development

Specific aspects of development of the person have been studied for centuries. Many theories of development are used in the study of individuals throughout the life span; the nurse may wish to refer to a text on developmental psychology to become familiar with some of these theories. In this unit, five theories are discussed to gain a holistic view of the progression of individual development throughout the life span. These theories were originally advanced by Erikson, Piaget, Vygotsky, Kohlberg, and Gilligan. Whereas these theories can assist in understanding developmental tasks, they are not definitive, and individuals may exhibit variations and stage activities may overlap.

Psychosocial Development: Erikson's Theory

Erik Erikson described the development of identity of the self through successive stages that unfold throughout the life span (Erikson, 1968, 1995; Erikson & Erikson, 1998). Although he studied with Freud and supported the psychosexual theory of development, **Erikson's theory of psychosocial development** is based on the need of each person to develop a sense of trust in self and others and a sense of personal worth. Erikson described a healthy personality in positive terms, not merely through the absence of disease.

According to Erikson, psychosocial development is composed of critical stages, each requiring resolution of a conflict between two opposing forces (e.g., intimacy versus isolation). Each stage depends on the preceding stage, which must be accomplished successfully for the person to proceed. Erikson's use of a psychosocial framework acknowledges the influence of socialization and the environment but maintains that it is ultimately the individual who must master each of the conflicts. Although each of the conflicts is predominant at a certain stage in life, it is important to recognize that all the conflicts exist in each person, to some extent, at all times and that a conflict, once resolved, may emerge again in appropriate situations. For example,

the renunciation and wisdom of old age is accomplished by a person reflecting on the crises of early development and coping with the physical and mental changes of aging (Perry et al., 2015). These stages are summarized in Table 15-3 and are discussed more fully in the chapters on each developmental age group. See the case study at the end of this chapter about a potentially disabled infant girl and how hospitalization could affect her stage of psychosocial development.

TABLE 15-3

GROWTH AND DEVELOPMENT
Erikson's Eight Stages of Human Development

Age Group	Psychosocial Stage	Lasting Outcomes
1. Infancy	Basic trust versus basic mistrust	Faith and hope
2. Toddler stage	Autonomy versus shame and doubt	Self-control and willpower
3. Preschool stage	Initiative versus guilt	Direction and purpose
4. School age	Industry versus inferiority	Method and competence
5. Adolescence	Identity versus role confusion	Devotion and fidelity
6. Young adulthood	Intimacy versus isolation	Affiliation and love
7. Middle adulthood	Generativity versus stagnation	Production and care
8. Older adulthood	Ego integrity versus despair	Renunciation and wisdom

Modified from Erikson, E. H. (1995). *Childhood and society* (35th anniversary ed.). New York: Norton; Erikson, E. H., & Erikson, J. M. (1998). *The life cycle completed.* New York: Norton.

Cognitive Development

Another aspect of development is cognitive development. Jean Piaget, a Swiss psychologist, also trained in biology and philosophy, is well known for his theory of cognitive development. He viewed children as biological organisms interacting with their environment, and his theory contends that cognitive development reflects children's attempts to make sense of their worlds. Piaget developed his cognitive theory by observing his own children (Piaget, 1950). Hence the major criticism of his work is that he underestimated children's capabilities and gave little or no consideration to cultural differences. Lev Vygotsky, a Russian contemporary, was also trained in both the physical sciences and psychology. His theory of cognitive

development maintains that a child's development cannot be separated from the social and cultural context in which it occurs. He also credited children with more innate ability to learn and emphasized the importance of language (Vygotsky, 1986). The theories of Piaget and Vygotsky are presented in more detail in the following sections.

Cognitive Development: Piaget's Theory

Jean **Piaget's theory of cognitive development** is concerned primarily with structure rather than content, with how the individual mind works rather than with what it does. Piaget uses the word scheme to describe a pattern of action or thought. A scheme is used to take in or assimilate new experiences or may be modified or accommodated by new experiences. Each person is striving to maintain a balance, or equilibrium, between assimilation and accommodation (Phillips, 1975; Piaget, 1950).

Piaget described the stages of cognitive development throughout the developmental years. Through a natural unfolding of ability, the child acquires sequentially predictable cognitive abilities. Given adequate environmental stimuli and an intact neurological system, the child gradually matures toward full conceptualized reasoning. Piaget's theory of cognitive development encompasses the time from birth to approximately 15 years of age. Each of the four distinct stages is summarized in Table 15-4 and is discussed more fully in the specific chapters on each developmental age. Piaget suggests that quantitative, but no further qualitative, changes in cognitive function occur after approximately age 15 years. Although more recent developmental theorists may dispute some of Piaget's findings, this scheme of cognitive development assists the nurse in assessing growth and development in children and adolescents (Carey et al., 2015).

TABLE 15-4

GROWTH AND DEVELOPMENT
Piaget's Stages of Cognitive Development

Stage	Age	Characteristics
Sensorimotor	Birth to 2 yr	Begins with a predominance and reliance on reflexes that permit the body to learn Reflexes decrease and voluntary acts develop Imitation predominates
		Thought is dominated by physical manipulation of objects and events Develops the concept of object permanence and the ability to form mental representations
Preoperational	2–7 yr	Advancing use of language and movement
		Development of egocentric, animistic, and magical thinking
		Uses representational thought to interpret and learn, not in terms of general properties but in terms of the relationship or use to themselves
		No cause-and-effect reasoning Thought is dominated by the senses—what is seen, heard, or experienced
Concrete operations	7–11 yr	Mental reasoning processes assume logical approaches to solving concrete problems, including cause and effect
		Collecting; mastering facts Can consider other points of view Thought influenced by social contacts Language is perfected
Formal operations	11–15 yr	True logical thought and manipulation of abstract concepts emerge Morality established

S., & Ashburn, S. S. (1992). *The process of human development: A holistic life span* approach (2nd ed.). Boston: Lippincott.

Cognitive Development: Vygotsky's Theory

One of the significant differences between the cognitive theories of Piaget and Vygotsky is that Piaget believed that development precedes learning. Piaget proposed that a level of cognitive development must be reached *before* learning can occur. Vygotsky thought that by viewing development and learning in this way, adults would teach to the lowest ability, aiming instruction at those mental functions or intellectual operations that had already matured in the child (Wink & Putney, 2002). In contrast, Vygotsky proposed that learning precedes development. He states that learning pulls development, which is in stark contrast to Piaget, who felt children are not capable of learning something until they are developmentally ready.

Vygotsky argued that, while learning may be similar among children at certain times or phases of development, it is not identical in all children because of their differing social and cultural

experiences (Vygotsky, 1978). He felt Piaget overemphasized the intellectual and biological universality of developmental stages. Vygotsky was more interested in the cultural and social influences on learning and development, as well as how individual children actively internalize what they learn from others. For Vygotsky, development begins as an interpersonal process of "meaning making," which then becomes an individualized process of "making sense." There are no predetermined levels of development; rather, experience is in the front—leading and expanding development in unlimited ways.

Although **Vygotsky's theory of cognitive development** is less known to health care professionals, educators have embraced his theory, especially what he refers to as the zone of proximal development. The **zone of proximal development** is the distance between the actual developmental level and the potential developmental level (Wink & Putney, 2002). In this zone, children are pulled toward new learning through their interaction with others and the environment. The guidance given by others in this zone is referred to as **scaffolding**. According to Vygotsky, all people need to understand not only the way in which an individual learns and develops but also the social, cultural, and political context in which that learning and development occur. This difference can profoundly impact how the nurse approaches teaching and learning (Box 15-4: Innovative Practice).

Box 15-4

Innovative Practice

How to Raise a Genius

The American Academy of Pediatrics (AAP, 2013) recommends *no screen time (television/video/computer/tablet/phone) for children younger than 2 years* and recommends limits on screen time for children older than 2 years. The AAP reports that active, not passive, adult-child communication is important to expand learning experiences for children (Boyce et al. 2015). Recent studies have associated television

watching with decreased language development. A study of 329 children ranging in age from 2 to 48 months found that even audible television that decreased the child's exposure to discernible adult speech led to decreased child vocalizations and delayed speech development (Christakis et al., 2009). In a similar study, television viewing by itself was significantly negative for the child younger than 2 years, but this negative result disappeared with the inclusion of two-sided adult-child conversations (Zimmerman et al., 2009). Previous studies reported that infants and toddlers learn faster and better when they are able to interact with adults, rather than just watch and listen (Boyce et al., 2015).

A later study of 3- to 5-year-olds refined these findings and indicated that the amount of television viewing negatively affected vocabulary and executive functioning, but this affect disappeared when the home learning environment was removed as a background variable (Blankson et al., 2015). A systematic review (Carson et al., 2015) of 37 studies of cognitive development in healthy children from birth to 5 years reported that the type of sedentary behavior, particularly television screen time as opposed to reading, may have differential effects on cognitive development. This study reported that further studies need to investigate the whole range of cognitive domains (language, spatial skill, executive function, and memory) to fully investigate the relationship between cognitive development and television viewing. Since the AAP guidelines were introduced in 2013, there has been an explosion in the use of digital devices including iPads, tablets and smartphones, and apps created for young children. Professional policy advice in this area may lag behind digital innovation (Brown et al., 2015). The nurse needs to convey to parents that the evidence supporting the recommendation for less television viewing for children from birth to age 5 years is evolving as this is studied further and access to digital devices increases.

- How can nurses talk to parents about the recommendation for television viewing for children younger than 2 years?

- How can nurses use the results of this study when teaching parents

that face-to-face interaction and two-way conversations with their children promote cognitive development more than watching television, videos, or other virtual media?

- Nurses should emphasize that role modeling is important and young children should observe the parent's on-line politeness and use of media

- How can nurses reinforce a focus that content matters and content quality is more influential than the media platform?

Moral Development: Kohlberg's Theory

Another aspect of cognitive development is the development of moral thinking and judgment. Lawrence **Kohlberg's theory of moral development** is based on interviews that focused on hypothetical moral dilemmas such as: Should a man steal an expensive drug that would save his dying wife? This question forms the basis of Kolhberg's classic Heinz dilemma. From interviews with boys, Kohlberg developed his theory, which is outlined in Table 15-5 (Kohlberg, 1969, 1981). The three stages of moral development—preconventional, conventional, and postconventional—were based on Piaget's theory of cognitive development and emphasize the ethics of

rights and justice. Progression through the successive stages of moral development generally occurs during the school-age, adolescent, and young-adult years. Beyond the young-adult years, stabilization or increased consistency of thought and perhaps an increased correlation between moral judgment and moral action occur (Kohlberg, 1981).

TABLE 15-5

GROWTH AND DEVELOPMENT
Kohlberg's Stages of Moral Development

Stage	Goal
Preconventional	Avoiding punishment
	Gaining reward
Conventional	Gaining approval
	Avoiding disapproval
Postconventional	Agreeing upon rights
	Establishing personal moral standards
	Achieving justice

From Kohlberg, L. (1981). *The philosophy of moral development* (Vol. 1). San Francisco: Harper & Row.

Moral Development: Gilligan's Theory

Carol **Gilligan's theory of moral development** (Gilligan, 1982, 2013; Gilligan et al., 1988) suggests that the process of moral development differs in women. While a doctoral student, Gilligan conducted research with Lawrence Kohlberg at Harvard University. She discovered that Kohlberg's original research was conducted with only men and that women often scored lower in Kohlberg's scaling of moral levels. She asserted that women were not inferior in their moral development, just different. In developing her own research with women, she proposed an alternative theory of moral development, which, like Kohlberg's, has three stages (Table 15-6). Gilligan concluded that the transitions between stages are based on changes in one's sense of self rather than on changes in cognitive development, as Kohlberg proposed. Gilligan more clearly differentiated the "voice of care" from the "voice of justice." She also reported that women think and act more from a base of caring and relationships than do men,

who are more inclined to think in terms of justice, rights, and rules. The voice of justice promotes legislative policies (e.g., immigration) and development of codes of ethics (McThomas, 2015); the voice of caring speaks to the importance of social relationships, which directs health practitioners to pay more attention to individual moral situations (Campbell, 2015).

TABLE 15-6

GROWTH AND DEVELOPMENT
Gilligan's Stages of Moral Development (for Women)

Stage	Characteristics	Goal
Preconventional	What is practical to others and best for self, realizing connection to others	Individual survival
Conventional	Sacrifices wants and needs to fulfill others' wants and needs	Self-sacrifice is goodness
Postconventional	Moral equal of self and others	Principle of nonviolence, do not hurt self or others

(1988). *Mapping the moral domain: A contribution of women's thinking to psychology and education.* Cambridge, MA: Harvard University Press.

Behavioral Biological Development

All the preceding theories discuss the importance of experience and environmental exposure on behavior and learning. One of the fundamental questions in the nature versus nurture debate is understanding how environmental stress (physical and behavioral) alters biological development (epigenetics). Evidence in animals and from human epidemiological studies indicates that experiences and the environment change the functioning of genes, and thus provide a basis for a model of gene-environment interaction. Early life experiences and social exposures may alter the way in which genes direct cell activities (Box 15-5: Genomics); early life adversity, including living in poverty, appears to result in DNA changes in the brain and other body tissues (Szyf et al., 2016). Recent studies suggest that even parental experiences can affect the behavior of children; brain plasticity theory describes brain cell development that can potentially modify ways individuals learn and experience their outside environment. This has implications for physical disease as well as attention and behavioral and mental disorders, and even the transmission of behavioral traits to the next generation (Szyf, 2015) (see Box 15-5: Genomics).

Box 15-5

Genomics

Epigenetics

- What Is Epigenetics?
- What are the associations between environmental stressors and physical and behavioral disorders?
- How can stressors, including poverty, affect more than one

generation?

Epigenetics is the scientific investigation of the capacity of cells to react differently to variations in environmental stimuli that are not related to the DNA code itself. The term epigenetics means "above genetics." Variations in cell response were historically attributed to changes in DNA gene sequences and the manufacture of cellular proteins with RNA transcription. However, this description does not fully explain why cells sharing identical DNA sequences can have differing appearances and effects. Some of this was attributed to cell mutations or alternative forms of genes (alleles). Again, this did not fully explain the full variety of appearances seen. Further scientific investigations showed that in two cells having identical DNA, the genes may be expressed differently. Cells are capable of regulating gene expression via the presence of regulatory proteins that wrap around DNA and RNA and can change cell function negatively or positively. Some of these regulatory proteins may turn off (repress) or silence cell function (methylation). Methylation and cell regulatory proteins are stable and heritable and separate from DNA genomic patterns. Epigenetic investigations have shown that these regulatory changes can be long-lasting and passed from one generation to the next. Stressors and/or maltreatment affecting one generation may have lasting behavior effects on subsequent generations. It is estimated that many of these epigenetic regulatory changes occur early in childhood and brain development (before the age of 3 years), and that poor early development influences risks of adult diseases (diabetes, obesity, heart disease, mental health and addiction problems) (Szyf et al., 2016; van Dijk, et al., 2015). There are also associations with attention deficit disorders, learning problems, and acquisition of language and numeral skills. Studies have linked poverty to brain impairment in early child development (Boivin et al., 2015). Whereas this science is in its infancy, and it is difficult to study human generational effects, there is no question that various stressors and physical and learning disorders affecting parents and children may be a problem for the next generation (Szyf, 2015), even when the original precipitating stressors are removed.

Case Study

Birth of a Disabled/Chronically Ill Child: Avery

Avery is a 33-year-old woman pregnant with her third child; her other two children are aged 5 and 10 years. At 26 weeks' gestation, Avery is hospitalized for contractions. Despite pharmacological attempts to stop labor, Avery's labor continues to the active phase. Avery and her partner just learned that a baby born this prematurely may have many problems, including cerebral palsy. As the perinatologist leaves the room, Avery turns to the nurse and starts to cry.

Reflective Questions

- What is the nurse's role when the parents learn a child has a chronic disease and/or disability?
- What can the nurse anticipate for these new parents during the labor? At the birth of the baby?
- What can the nurse anticipate in the first 2 weeks after birth? Over the baby's first year of life? Over the first 5 years?
- How will this child's growth, development, and goals for health promotion be affected? What about those of the parents? What about those of the siblings?

- What factors might contribute to Avery's development of chronic sorrow?
- If Avery becomes depressed, how might this affect the growth and development of the new baby? What effect might this have on her relationship with her partner? What effect might her depression have on her other children?
- What will be the impact of this child's disabilities on the siblings?
- How might the nurse intervene to lessen the effects of chronic sorrow?

Care Plan

Birth of a Disabled/Chronically Ill Child: Avery

***NURSING DIAGNOSIS: Chronic sorrow (parental) related to missed opportunities and unending caregiving for a new child**

Definition

Cyclical, recurring, and potentially progressive pattern of pervasive sadness experienced (by a parent, caregiver, individual with chronic illness or disability) in response to continual loss, throughout the trajectory of an illness or disability

Defining Characteristics

- Parental expression of disparity between preconceived notions of parenting and reality
- Parental expression of an ongoing or recurrent sense of sadness or loss
- Parental expressions of negative feelings (e.g., anger, depression, disappointment, emptiness, frustration, self-blame, helplessness,

hopelessness, loneliness, overwhelmed) that are often triggered by health care crises or conflict with expected social norms for child or family

Related Factors

- Change in family structure
- Change in parental role expectation
- Parental coping styles

Goal

- Assist family unit to attain, maintain, or regain optimal health

Expected Outcomes

- Grief resolution: *Adjustment to actual or impending loss.* For example, parents verbalize reality of loss, progress through stages of grief, decreasing preoccupation with loss, verbalize acceptance of loss, resolve feelings about loss.
- Hope: *Optimism that is personally satisfying and life-supporting.* For example, parents express inner peace, expectation of a positive future.
- Psychosocial adjustment: *Adaptive psychosocial response of an individual to a significant life change.* For example, parents set realistic goals, maintain productivity, verbalize optimism about present, use effective coping strategies, report feeling socially engaged.

Nursing Interventions

- Grief work facilitation: *Helping another cope with painful feelings of actual or perceived responsibility.* For example, listen to expression of

grief, encourage identification of fears, assist in identifying needed modifications in lifestyle.

- Hope inspiration: *Enhancing the belief in one's capacity to initiate and sustain actions.* For example, help identify areas of hope in their lives, demonstrate hope by recognizing the disability or illness as only one facet of the child, provide parents with opportunities to be involved with support groups, especially with other parents of children who are disabled/chronically ill who have transcended.

- Coping enhancement: *Assisting a person to adapt to perceived stressors, changes, or threats that interfere with meeting life demands and roles.* For example, provide an atmosphere of acceptance, seek to understand each parent's perspective of the situation, appraise and discuss alternative responses to the situation, foster constructive outlets for negative feelings, assist the parents to identify positive strategies to deal with limitations and manage necessary lifestyle changes.

- Resiliency promotion: *Assisting individual, families, and communities in development, use, and strengthening of protective factors to be used in coping with environmental and societal stressors.* For example, encourage positive health-seeking behavior, facilitate development and use of neighborhood resources.

Summary

Individuals make many choices that affect their health each day, and a number of factors influence how these choices are made. The stage of growth and development, as well as the context in which learning occurs, influences how individuals experience different situations and realize the choices available. Understanding the most widely used theories of human growth and development assists nurses to have a clear understanding of the challenges an individual is likely to encounter, as well as the skills the individual is likely to need, for successful growth, development, and maturation throughout the life span. Theories provide nurses with frameworks, resources, and comparisons for health assessment, promotion, and intervention.

16

The Childbearing Period

Susan Scott Ricci

OBJECTIVES

After completing this chapter, the reader will be able to:

- Differentiate fetal development and the newborn transition to extrauterine life.
- Analyze changes in the maternal system during pregnancy on the basis of their influences on pregnancy adaptation.
- Interpret the role of the nurse in promoting the physical, mental, and spiritual health of the childbearing family.
- Compare and contrast fetal problems caused by maternal drinking, smoking, drug use, and viral exposure during pregnancy.
- Outline the nursing role during labor and birth with a focus on the physical, emotional, spiritual, and educational needs of the woman giving birth and her family.
- Evaluate the influence of factors such as ethnicity, legislative priorities, and the sociopolitical context of the health care delivery system on prenatal and childbirth care and the needs of families.

Think About It

First Pregnancy Labor

Laura, currently 41 weeks into her first pregnancy, is admitted at 2:00 a.m. to St. Jude's Medical Center with uterine contractions occurring every 8 minutes since midnight. Her cervix is dilated to 2 cm and is 80% effaced, and her station is −3. Her husband is out of town on a business trip, and

Laura's neighbor has accompanied her to the hospital. Although Laura attended Lamaze classes with her husband, she is anxious about the labor. She says to the nurse, "My back is about to break, I have so much bottom pressure, and I wanted to go natural, without medication and all this high-technology stuff, including the monitor."

- On the basis of your knowledge of ethical and legal principles of care, how would you as a caregiver appropriately respond to Laura's needs with labor and birth?
- What factors in Laura's database would support the use of the fetal heart monitor? What factors would not support use of the monitor?
- What political, legal, ethical, and other factors might be relevant to the widespread use of monitors in American maternity units today?
- How does the use of fetal heart rate monitoring fit into a health-promotion approach to labor and birth?

The process of **conception**, pregnancy, and birth involves a complex interaction of many factors, including the physiological and psychological changes in the woman and family and the development of a **fetus** into a viable newborn. The nurse's role during the pregnancy cycle should encompass evidence-based practice recommendations for effective health-promotion interventions prenatally, intranatally, and postnatally to improve maternal and newborn health outcomes. The focus of this chapter is on the pregnant woman, her family, and the developing fetus; discussing one without the others is impossible. The nurse must consider all three entities when seeking to promote a healthy pregnancy and healthy family system after birth.

Biology and Genetics

Cells are the basic units of life. Pregnancy begins with fertilization, the fusion of a sperm from a male and an egg from a female. Each one contains half of the genetic material to form a new individual. Fertilization is the first embryonic event in a series that culminates in the birth of an infant. The physical changes during pregnancy include natural processes involving fertilization of the egg by the sperm, implantation of the fertilized egg into the uterus, embryonic or fetal growth and development, placental development and function, and maternal changes related to the pregnancy process.

Duration of Pregnancy

Pregnancy begins with the union of a sperm and an egg, a process called **fertilization**. Under normal healthy circumstances, a full-term pregnancy lasts approximately 9 solar months, 10 lunar months, or 40 weeks. An accurate estimated date of delivery is determined by use of Nägele's rule. One does this by adding 7 days to the date of the first day of the last normal menstrual period and subtracting 3 months. A usual pregnancy consists of 9 months, divided into three equal periods called **trimesters**. Often these trimesters form the basis for discussion of expected fetal and maternal changes during pregnancy.

Fertilization

The union of a sperm and an egg requires several crucial factors, many of which are not fully understood. When a sperm cell penetrates an egg in the ampulla of the fallopian tube, the beginning of a human being (called a *zygote)* results. Early cell divisions occur while the zygote is slowly being transported through the fallopian tube toward the uterus. Additional division of **zygotic cells** results in more differentiated structures that eventually produce an embryo and subsequently a fetus.

An absence of one or more critical factors may cause **infertility**

(failure of the couple to become pregnant despite usual sexual activity in a period of 1 year). For example, both a sperm cell and an egg cell must be mature and in the fallopian tube for approximately 5 hours for union of the sperm and egg to occur (the process of conception). The sperm must be of uniform size, be normally formed, possess high motility, and have an ability to secrete enzymes that dissolve the membrane surrounding the egg. Cellular changes within the egg prevent other sperm from entering the ovum after the sperm penetrates it (Mattson & Smith, 2015). The woman attempting pregnancy must have a certain basal body temperature and fallopian tubes free of adhesions or obstructions. A woman will likely conceive within 24 hours after ovulation.

Implantation

The process of attachment and placental formation is called implantation. A pregnancy has not occurred until successful implantation has happened. The placenta is an organ that serves to prevent the direct exchange between the blood of the fetus and the blood of the mother. It also functions as an endocrine gland, manufacturing and secreting hormones that play a vital role in maintaining the pregnancy. Transplantation of the fertilized egg in the uterine cavity after its trip through the fallopian tube requires approximately 6 days (Mader & Windelspecht, 2015). Once the zygote reaches the uterus, it stays there for up to 5 days, receiving nutrition from the **endometrium**, the inner lining of the uterus (El-Mazny, 2014). The process of fertilization and implantation triggers the production of large amounts of the hormone **progesterone**, which stimulates the formation of endometrial cells known as the decidua, meaning "to shed." The decidua provides nutrition for the **embryo**, a term that defines the growing conceptus up to 8 weeks of age.

Fetal Growth and Development

Much is known about the stages of physical development in each structural system of the embryo. However, metabolic functions,

particularly those relevant to the endocrine and neurological systems, are less well defined. Appropriate fetal development depends on these events occurring in a specified period and order during each trimester of pregnancy. If this does not occur, an abnormality in structure or function (a **congenital defect**) may result. This defect may be noted at birth, did not occur at conception (called a genetic defect), but most likely resulted from some disruption that occurred after conception and during fetal development.

Placental Development and Function

After implantation of the zygote, the **placenta** develops through an integration of embryonic and decidual cells. The **chorionic membranes** and **amniotic membranes**, which surround the fetus throughout **gestation**, also begin to form. The amniotic fluid, manufactured by the amniotic membrane, supports the developing fetus and protects it from injury.

The basic structure of the placenta allows maternal-fetal blood exchange to nourish the fetus and allow excretion of fetal waste products. Throughout most of gestation, increasing placental development allows maternal blood to flow through the intervillous spaces and fetal blood to flow through the **chorionic villi** (Cunningham et al., 2014). The unique structure of the placenta permits the exchange of certain molecules but prevents fetal and maternal blood supplies from mixing for most of the pregnancy. Substances with larger and heavier molecules (such as heparin or insulin) normally do not pass through the placenta to the fetus, but lighter molecules (such as anesthetic gases, oxygen, carbon dioxide, and electrolytes) readily cross the placenta. Because of the difficulty involved in predicting exactly which substances will cross the placenta, the nurse needs to encourage pregnant women and those contemplating pregnancy to avoid any substance that might cause harm to the fetus.

The placenta manufactures and secretes four hormones throughout pregnancy. The primary hormones produced by the placenta include estrogen, progesterone, human chorionic gonadotropin (hCG), and

human placental lactogen (hPL). Estrogen's role is to increase uterine blood flow and increase uterine and breast growth. Progesterone maintains the uterus in a quiet state throughout the pregnancy to prevent labor contractions occurring too early. hCG's main role is to sustain estrogen and progesterone production in early pregnancy, and it is also the hormone detected in pregnancy tests. hPL ensures adequate fetal nutrition, increases insulin resistance, and stimulates production of growth hormones (King et al., 2015).

The fetus, which continues to gain strength and maturity during the later weeks of gestation, generally rests its head in the lower maternal pelvis by the end of pregnancy (Figure 16-1). The membranes protect the fetus from infection and act as a container for the amniotic fluid. As birth begins, the membranes may rupture, causing the loss of amniotic fluid and stronger uterine contractions, reflective of the **labor** process. If the membranes rupture more than 24 hours before birth, uterine infection and potential fetal harm may result.

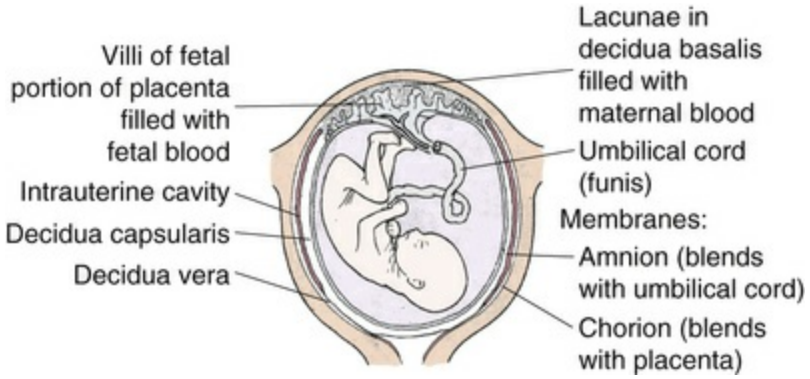

FIGURE 16-1 Relationship of fetus, placenta, membranes, and uterus during gestation. (From Lowdermilk, D., Perry, S., Cashion, K., & Alden, K. R. [2016]. *Maternity and women's health care* [11th ed.]. St. Louis: Mosby.)

As gestation nears completion, placental function gradually decreases, which may serve as a stimulus for the onset of labor. When pregnancy continues beyond 42 weeks, or 2 weeks beyond the calculated due date, placental function decreases even more, posing concerns about the well-being of the fetus (Blackburn, 2014).

The discussion of fetal development provides only a brief glimpse of the prenatal period. It is also important to address maternal changes and culmination of the prenatal period, labor, and birth.

Maternal Changes

A woman experiences various physiological effects based on a combination of hormonal and mechanical changes during pregnancy. Hormonal influences tend to increase as the pregnancy progresses. The mechanical (hemodynamic) changes reach a peak in the seventh or eighth month and then gradually decline as the pregnancy nears completion (Cunningham et al., 2014). Clinical symptoms will manifest themselves during this peak stress time.

Signs of Pregnancy

A woman may assume that she is pregnant because she has skipped her menstrual period or experiences nausea and vomiting, changes in breast sensations and size, or increased urinary frequency (presumptive signs of pregnancy). Presumptive signs of pregnancy are the least reliable indicators of pregnancy because any one of them can be caused by conditions other than pregnancy. If she suspects she is pregnant, the woman should undergo a pregnancy test. If it is performed too early, a home pregnancy test may produce a false negative result attributable to a low level of **human chorionic gonadotropin (hCG)**. This hormone, produced by the placenta and found in a pregnant woman's urine and blood, triggers a positive pregnancy result. These home pregnancy tests have a high degree of accuracy (97%) if the instructions are followed exactly. If the pregnancy test is positive, a prenatal visit should be scheduled to estimate gestational age and for the woman to receive appropriate pregnancy counseling, which should include taking folic acid supplementation to prevent neural tube defects (NTDs), if she has not already started taking it preconceptually. All women of reproductive age should supplement their diet before conception with 0.4 to 1.0 mg of folic acid daily as part of their multivitamins. The incidence of

NTDs (~1 in 1000 live births in the United States) has fallen since the inclusion of folic acid supplementation, but recent research suggests folic acid supplementation is underused because of low adherence (Chitayat et al., 2016). As the pregnancy progresses, the woman may experience **presumptive signs of pregnancy**, which are subjectively experienced; **probable signs of pregnancy**, which are objectively observed by the health care provider; and **positive signs of pregnancy**, which are positive signs that verify that a pregnancy exists (Box 16-1). During the first trimester of pregnancy, using sophisticated testing with **ultrasound**, health care providers can determine fetal presence and placental adequacy early in pregnancy. This technology, which uses high-frequency sound waves that bounce off the fetus and are interpreted by a computer, allows visualization of the fetus and gestational structures throughout pregnancy (Norwitz & Schorge, 2015).

Box 16-1

Signs of Pregnancy and Time of Occurrence

Presumptive

- Breast changes (e.g., tenderness) (3–4 weeks)
- Fatigue (12 weeks)
- Urinary frequency (6–12 weeks)
- Nausea and vomiting (4–14 weeks)
- Amenorrhea (4th week)
- Quickening (16–20 weeks)

Probable

- Enlargement of the uterus (12–14 weeks)

- Softening of the uterine isthmus (Hegar sign) (6th –12th week)
- Bluish or cyanotic color of cervix and upper vagina (Chadwick sign) (6th–8th week)
- Softening of the cervix (Goodell sign) (5th week)
- Ballottement of the fetus (16th –28th week)
- Positive test result for hCG in the maternal urine or blood serum (4th –12th week)
- Changes in skin pigmentation (chloasma and linea nigra) (2nd half of pregnancy)

Positive

- Detection of fetal heart tones by auscultation, ultrasonography, or a Doppler scan (8–17 weeks)
- Palpation of fetal body parts with Leopold maneuvers (19–22 weeks)
- Fetal movements visible and detected by examiner (late pregnancy)
- Radiological or ultrasonographic demonstration of fetal parts (6–16 weeks)

hCG, Human chorionic gonadotropin.

Nausea and vomiting in pregnancy occurs in up to 80% of women, and there is a tendency for many health care providers to minimize it. The Food and Drug Administration has approved Diclegis to treat nausea and vomiting in women whose symptoms have not abated with a change in diet or other nonmedical treatments. It is a delayed-release medication containing a combination of doxylamine (antihistamine) and pyridoxine (vitamin B_6). The major side effect is

drowsiness (Brucker & King, 2017).

Adaptive Changes of Other Systems

In addition to pregnancy-related changes in the reproductive system, adaptive changes in other body systems occur. The urinary system undergoes dramatic changes during gestation as follows:

- A 50% increase in glomerular filtration rate occurs related to the influences of **estrogen** and progesterone.
- Ureters increase in diameter by 25% secondary to progesterone influence.
- Urinary output increases by approximately 80% related to the total body water increase.
- Bladder capacity increases to approximately 1500 mL to accommodate extra fluids.

The cardiovascular system changes also begin early in pregnancy as follows:

- Cardiac output increases by up to 50% to meet the demands of pregnancy.
- Total blood volume increases by up to 45% during pregnancy. Physiological anemia of pregnancy may result because of a greater increase in the volume of plasma compared with the volume of red blood cells.
- Heart rate increases by 10 beats per minute to compensate for the increase in blood volume.

Respiratory system changes include the following:

- Tidal volume (volume of air inspired) increases by 30% to 40% to increase the effectiveness of air exchange. Total oxygen consumption increases by approximately 20%.
- The diaphragm is displaced upward secondary to the enlarging uterus and causes shortness of breath during the last trimester.

Increased elasticity and softening of connective tissue of the musculoskeletal system cause the following changes during

pregnancy:

- The joints relax, especially the pelvic joints that support the pregnancy and create pliability at the time of birth.
- Lumbar and dorsal curves of the spine increase late in pregnancy and contribute to low back pain and the waddle of pregnancy.
- Separation of the symphysis pubis occurs secondary to the influence of the hormone relaxin.

Changes in the integumentary system occur, which may include the following:

- Hormonal changes and stretching of the connective tissue of the abdomen attributable to an enlarging uterus lead to stretch marks **(striae gravidarum)**.
- A narrow, brownish line **(linea nigra)** divides the abdomen, running from the umbilicus to the symphysis pubis. The linea nigra fades after the pregnancy ends.
- An increase in pigmentation caused by melanocyte-stimulating hormone causes darkened areas on the face termed the mask of pregnancy **(chloasma)**.

The gastrointestinal system undergoes dramatic changes during pregnancy, such as the following:

- The enlarging and space-occupying uterus cramps the intestinal region, causing a slowing of peristalsis and an increase in the emptying time of the stomach.
- Relaxin causes a decrease in gastric motility leading to constipation.
- Frequent "heartburn" results from reflux of stomach contents into the esophagus secondary to upward displacement of the stomach and a relaxed gastroesophageal sphincter (King et al., 2015; Tharpe et al., 2016).

Reproductive System

The effects on the reproductive system include changes in the uterus, breasts, vagina, vulva, and ovaries. The prepregnant uterus is

approximately the size of a closed fist. The uterus at term has the capacity to contain a 3.2 to 4.5 kg (7–10 lb) infant and the placenta. As the uterus enlarges, the **fundus** (the upper uterine segment) moves higher in the abdomen (Figure 16-2). The breasts begin enlarging early in the pregnancy, and in late pregnancy they may secrete small amounts of **colostrum**, a precursor of mature breast milk. The vagina and vulva receive a greater blood supply and appear darker (cyanotic) as a result. Some women will notice an increase in vaginal secretions and experience a whitish discharge (Mattson & Smith, 2015).

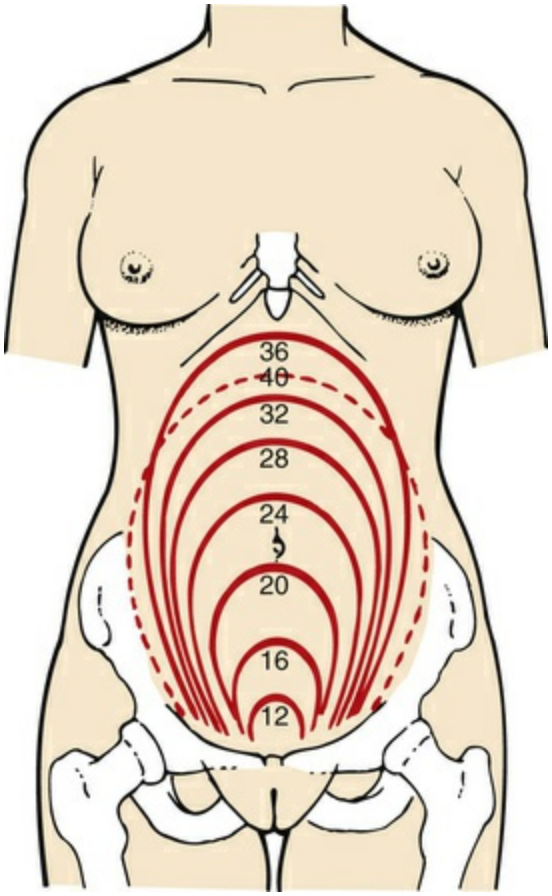

FIGURE 16-2 Upper level of enlarging uterus by weeks of normal gestation with a single fetus. (From Seidel, H. M., Ball, J. W., Dains, J. E., Flynn, J. A., Solomon, B. S., & Stewart, R. W. [2015]. *Mosby's guide to physical assessment* [8th ed.]. St. Louis: Mosby.)

Hormones such as hCG and estrogen, secreted by the placenta and

the fetus, create an optimal intrauterine environment for the fetus and stimulate many changes in the pregnant woman's body. The developing fetus contributes to the provision of an adequate environment for its own growth and nourishment, despite the possibility of creating discomforts for the pregnant woman.

Preconception Care of Women

Preconception health promotion is a primary intervention that benefits reproductive-age women and their potential children. Prenatal care has been used as secondary prevention to improve the health of the woman during her pregnancy, but by the time prenatal care has generally started at weeks 8 to 12, a considerable amount of fetal development has already occurred. The fetus is most sensitive to maternal health and environmental exposures from weeks 4 to 10 of pregnancy, and many women may not know they are even pregnant then. The rates of adverse birth outcomes (preterm and low birth weight, infant deaths, and birth defects) and maternal pregnancy complications in the United States are all higher than the goals in *Healthy People 2020.* Given the adverse trends seen in preterm birth rates and related infant death rates, a comprehensive public health research agenda that investigates the social, genetic, and biomedical factors contributing to these adverse outcomes was convened by the Centers for Disease Control and Prevention (CDC). The Action Plan for the National Initiative on Preconception Health and Health Care (Johnson et al., 2014) put forth the following objectives:

- Improve the knowledge, attitudes, and behaviors of men and women related to preconception health.
- Create health equity and eliminate disparities in adverse maternal, fetal, and infant outcomes.
- Ensure that all women of childbearing age receive preconception care services and enter their pregnancy in optimal health.
- Reduce risks among women who have prior adverse maternal, fetal, or infant outcomes through interventions during the postpartum and interconception periods.

The key points introduced included that preconception health is a gateway for broader conversations about women's wellness, that health practices and policies with an individual focus have finite success, and that researchers have been advocating broadening the spectrum of improving health using life course for more than a decade (CDC, 2015a).

Not all couples who seek preconception care are able to conceive on their own. Conception requires ovulation of a mature ovum, normal fallopian tubes, the presence of progressively motile sperm in the female reproductive tract, and an endometrium favorable for implantation. For many couples the experience of fertility problems and aspects of the care with uncertain outcomes can be stressful and distressing. Infertility is defined as a failure to conceive after 1 year of regular and unprotected sexual intercourse. Infertility affects more than 7 million American couples (Frankford et al., 2015). Frequently couples will seek treatment for their infertility issues and undergo testing that may include a semen analysis, assessment of ovulation, evaluation of tubal patency, and tests for ovarian reserve (Galliano & Pellicer, 2015). The nurse's role is that of support and education of the couple. The nurse can assist in educating the couple about the various methods to treat infertility and allow them to make their own decision as to which method is best for them. Infants conceived through in vitro fertilization (IVF) technologies have a higher risk of genetic abnormalities, being part of a multiple pregnancy, and being born prematurely (Green et al., 2015). The nurse must be knowledgeable to be able to respond to questions that will come up throughout the treatment experience. One of the greatest risks of assisted reproduction is the risk of obtaining a multiple pregnancy after intrauterine insemination with more than one embryo. Compared with a single pregnancy, the risks of a multiple pregnancy include iron- and folate-deficiency anemia, gestational hypertension, preeclampsia, polyhydramnios, gestational diabetes, and a high surgical birth rate (De Sutter, 2015). Most couples need a great deal of emotional support, and it is important for the nurse to be able to act as an advocate for them, particularly those using gestational surrogacy

as a means of achieving parenthood.

Surrogacy is an arrangement in which a woman carries and gives birth to a child for another couple. The fundamental nature of families has changed over the years, whereby gestational surrogacy as an option for infertile couples is widely accepted. Gestational surrogacy, where the surrogate is not genetically related to the embryo, has become the norm. Surrogate motherhood is treated as a form of adoption in many countries: the birth mother and her partner are presumed to be the parents of the child, whereas the intended parents have to adopt the infant once it is born. Other than compensation for expenses related to the pregnancy, payments to surrogates are not allowed. The legal aspects of surrogacy are very complex and differ among countries (Jalili, 2015).

Preconception care before a pregnancy implies health-promotion activities that are conducted before a pregnancy occurs to address risk factors across the life span—including during adolescence. Although most pregnancies during adolescence are unintended, health behaviors initiated during this period can have a great impact, not only on future reproductive outcomes but also on present and future health.

Preconception care offers an effective and efficient means to reduce complications of pregnancy for both the mother and her newborn. Women should be made aware that certain preconception interventions may improve not only the outcomes of pregnancy but also the overall health of the woman as well. The following interventions may be included:

- Folic acid supplementation to reduce the risk of NTDs
- **Rubella** vaccination to reduce the risk of severe congenital defects
- Diabetes management to reduce the risk of birth defects threefold
- Hypothyroidism management to promote healthy fetal neurological development
- **Hepatitis B** vaccination for at-risk women to prevent chronic liver disease
- Human immunodeficiency virus (HIV)/acquired immunodeficiency

syndrome (AIDS) screening and treatment to prevent transmission to the fetus
- Healthy diet instruction throughout pregnancy
- Physical activity needs throughout pregnancy
- Substance use and medication safety
- Intimate partner violence screening
- Counseling women about immunizations for themselves and their infants
- Assessment of chronic health conditions such as diabetes, hypertension, and thyroid disease
- Screening and treatment for sexually transmitted infections (STIs) to reduce the risk of ectopic pregnancy and/or fetal anomalies
- Oral antiepileptic medication management to minimize birth defect potential
- Cessation of acne treatment with isotretinoin (Accutane) to prevent defects
- Smoking cessation counseling to reduce negative perinatal outcomes
- Screening and treating of depression to reduce the risk of postpartum depression
- Elimination of alcohol use to prevent fetal alcohol spectrum disorders
- Obesity control to reduce the risk of cerebrovascular disease, diabetes, or surgical births (CDC, 2015a)

As a group, nurses are challenged to effectively translate the concept of preconception care to all women in their practice setting. By informing women that existing health conditions and medications can affect pregnancy outcomes, nurses can provide a positive environment for the woman's future pregnancy and improve overall health practices.

Normal Discomforts of Pregnancy

Changes in the woman's body during pregnancy support a nursing

diagnosis of *alteration in comfort with relevant interventions* for most women. Women may feel a sense of relief that other pregnant women have these concerns and that interventions exist to increase their comfort at various points during gestation. Particularly for those experiencing a first pregnancy, the nurse serves as a valuable support person to help expectant couples adjust to the challenges and discomforts of pregnancy, a goal for the earlier-stated diagnosis.

Teaching the Woman About Changes to Expect in the Body During Pregnancy

In addition to serving as a caregiver, advocate, and support person, the nurse serves as a teacher throughout the pregnancy care process. Active teaching responsive to an individual's concerns about pregnancy may occur in the clinic, physician's office, or other care environments. Nursing interventions should address recommended professional practice guidelines for education during the prenatal period to prevent complications for the family. For example, the nurse may offer textbooks, pamphlets, DVDs, and referrals to websites and other media to increase a couple's knowledge of fetal, maternal, and family changes during gestation and then encourage and answer any questions based on the material. Going beyond one-to-one teaching, the nurse may also refer couples to early pregnancy and **Lamaze** childbirth preparation classes to enlarge their social support network and increase knowledge of labor and birth. Throughout the care process the nurse is sensitive to the cultural and ethnic beliefs and behaviors of the individual or family. By incorporating knowledge of these beliefs and behaviors, the nurse protects the pregnant woman and her baby by providing individualized care addressing the childbearing rituals practiced by various cultural groups (Table 16-1). A summary of perinatal care guidelines is provided in Table 16-2.

TABLE 16-1

Cultural Values Related to Pregnancy and Birth

Filipino	Structured prenatal care for those who can afford it. Pregnancy normal event with family focused on pregnant woman's needs. Pregnant woman encouraged to eat well, sleep often, and not to work out of home. Sexual intercourse taboo during last 2 wk of pregnancy. Pregnant woman encouraged to eat fresh eggs close to delivery to help baby "slide out" with birth. Woman very modest about body needs and care during pregnancy. Father passive with birth process; pregnant woman active participant with birth. Breastfeeding encouraged until child is a toddler
American Indian	In many tribes, women are expected to seek prenatal care with pregnancy; some tribes accept late care. Dialogue with women in tribal community important to maximize pregnancy and birth process. Meditation, self-control practice, and indigenous plants (herbal teas) used for discomforts of pregnancy and birth. Pregnant woman stoic about birth process; father present but not active participant. Female kin present to support woman in labor; breastfeeding and bottle feeding encouraged after birth. Father may avoid hunting immediately after birth or until infant's umbilical cord detaches
Arab American	Pregnancy normal event; may not access prenatal care because of that belief. Much family support given to pregnant woman to allow maximal rest and minimal work. Present orientation: little preparation for birth, fears labor pains but responds once they come. Expressive with labor but not active with control of pain; relies on family members for support; father not active, may feel powerless with birth process. Very modest about care, especially with opposite-sex health care provider. Prefers bottle feeding; colostrum believed to harm baby
Black	Most access prenatal care after first trimester or seek care earlier with problems. Female kin provide most of support with pregnancy and birth; male support less visible. Open expression of pregnancy and birth discomfort; active participant in birth process. May self-medicate with cultural remedies for pregnancy complaints. May avoid being in photographs because of fear of stillbirth. May crave certain foods: chicken, greens, clay, starch, or dirt (pica). If of Muslim faith, may wish to have head covered during labor and birth process. Breastfeeds if given information on the benefits of this method
Mexican American	Often face barriers to prenatal care because of lack of insurance, fear of health care system, lack of transportation to clinic. May consider prenatal care not necessary because childbirth is normal life event. Education and acculturation influence prenatal care access. Pregnancy considered to follow marriage; family supports respect of and assistance to pregnant woman. Pregnant woman does not smoke, work, drink alcohol, or use drugs; pregnancy a time to rest, walk, eat well, sleep, drink chamomile tea, and avoid cold air. Grandmother may move into the home close to delivery time to help and provide folk remedies after birth. Modest about care and needs; same-sex health care provider encouraged. Generally, walks during labor to enhance birth; wants family for support; woman active and father delegates support to female members of family. Generally, breastfeeds for up to 1 yr
Vietnamese	Generally early prenatal care unless immigrant status, then depends on family for care. Encouraged to eat healthy foods, get rest, avoid strenuous activity during last trimester. Focus on keeping pregnant woman warm, encouraging salt water for oral care, and maintaining good hygiene. Sexual intercourse taboo with pregnancy. Father present but not active with pregnancy. Birth a time of hot and cold imbalance; mother "suffers in silence," may moan or grunt; mother depends on female relatives for support and guidance. Mother breastfeeds for up to 1 yr; avoids cold foods for this period

NOTE: General ideas about beliefs and behaviors of each of these cultural groups have been given with no intent to stereotype all individuals who represent these groups' beliefs or behaviors. It is hoped that this information will provide direction to the nurse, who will continue to assess each individual to render care that meets each person's traditional values in a biomedical model of health care in the United States today.

TABLE 16-2

Perinatal Care Guidelines

First Trimester	Second Trimester	Third Trimester	Labor Stages	Postpartum
Complete assessment to identify risk factors	Assess adaptation to pregnancy and fetal well-being	Review physiological changes	Admission to birthing facility	Complete a head-to-toe physical assessment: breasts, uterus, bladder, bowels, lochia Emotional status Circulatory status Episiotomy
Awareness of subtle or overt physical, sexual, or emotional abuse	Update heath history	Monitor changes related to pregnancy	*First stage:* Complete maternal/fetal assessments Determine labor progress Assist with comfort measures Monitor fetal heart rate Support family in their efforts Praise efforts	Assess mother for postpartum blues/depression
Assess physical and psychosocial progress in adaptation to pregnancy	Continue to recognize cultural influences	Assess expectant family's readiness for labor, birth, and parenting role	*Second stage:* Offer encouragement Assist with pushing efforts Document activities	Encourage bonding and attachment
Inquire about physical changes and discomforts; explain	Encourage informed decision-making and positive health care	Review finalized birth plan	*Third stage:* Provide care as needed	Demonstrate breastfeeding techniques

causes and identify appropriate relief measures	practices		Document time of placental delivery Administer medications as ordered	
Provide anticipatory guidance appropriate for the woman's individual needs	Review potential risk factors and when to report them	Identify community resources available to the family	*Fourth stage:* Monitor vital signs; fundus, assess bladder status Encourage parental-infant interaction Monitor newborn's well-being Provide perineal care, food, fluids Provide family support	Provide anticipatory guidance needed for the family
• Educational needs: hazards during pregnancy • Use of drugs, alcohol, and smoking	Ensure community referrals/resources as needed. Educational needs: Oral hygiene Nutritional needs	Explain any diagnostic tests ordered. Meet educational needs: needs for newborn care		Educational needs: Nutrition Fatigue Child care
Seat belts, high-risk behaviors Warning/danger signs to report Nutrition and weight management Sexuality	Safety issues in workplace Discomforts of pregnancy. Relief of common discomforts of pregnancy Prepared childbirth classes	Monitoring fetal movements Strategies to cope with discomforts Promote family safety Including partner in process Childbirth preparation		Immunizations Sexuality Family planning Breast engorgement Family adaptation Follow-up care needed Danger signs to report Sibling readiness for new member Self-care activities

Prenatally, pregnant women experience a wide variety of physiological adaptations. Nurses must possess a broad and deep understanding of these changes combined with accurate and early risk assessment to identify deviations. This knowledge base is vital for nurses caring for women during the childbearing cycle.

Total Weight Gain

Total weight gain during pregnancy reflects not only the growth of

the baby and placenta but also the growth of the uterus and breasts, the storage of maternal fat, and the increased amounts of blood and other body fluids. It has been nearly 2 decades since guidelines for how much weight a woman should gain during pregnancy were issued by the Institute of Medicine (IOM). More research has been conducted on the effects of weight gain in pregnancy on the health of both the mother and her baby. Excessive weight gain is one of the most important potentially modifiable factors associated with adverse pregnancy outcomes. The IOM released new weight gain guidelines in 2009 that are based on revised body mass index (BMI) categories and now have a recommendation for obese women. However, the IOM did not differentiate women by age, race/ethnicity, or subclasses of obesity. As a result, the weight-gain guidelines span a wide range, and nurses are challenged to individualize their dietary counseling for the obese individual. To meet the recommendations of the report, women need to gain weight within the weight-gain ranges for their BMI category. Achieving the recommended weight gain will require individualized attention and support from a woman's care providers, as well as her family and community. Nurses are uniquely positioned to educate pregnant women about the IOM guidelines for weight gain in pregnancy and the importance of a healthy diet and adequate physical exercise. In addition, the Internet, social media, and eHealth technologies provide unprecedented opportunities to efficiently reach and educate influential family members, friends, and the media. Utilization of these modalities can quickly transform unhealthy cultural norms and prevent significant morbidity among generations of at-risk women and children (Chang & Moniz, 2015).

The new IOM guidelines reflect changing US demographics, particularly the surge in the number of women who are overweight or obese. The new guidelines advise that healthy women at a normal weight for their height (BMI of 18.5–24.9 kg/m^2) should gain 25 to 35 pounds during pregnancy. Underweight women (BMI less than 18.5 kg/m^2) should gain more, 28 to 40 pounds, and overweight women (BMI of 25–29.9 kg/m^2) should gain less, 15 to 25 pounds. Obese women (BMI greater than 30 kg/m^2) should limit their gain to 11 to 20

pounds (IOM, 2015).

Obesity is a public health concern worldwide and has reached alarming proportions. It is arising from multifaceted and complex causes that relate to individual choice and lifestyle, and the influences of wider society. In addition to a long-standing focus on both childhood and adult obesity, there has been more recent concern relating to maternal obesity. Infants of obese mothers are more likely to be born prematurely, to be stillborn, or to die in the first 28 days of life. Obesity increases the risk of obstetrical complications during the prenatal, intrapartum, and postnatal periods, as well as contributing to technical difficulties with fetal assessment. In addition, infants of obese mothers are more likely to be born with a congenital abnormality (Lim & Mahmood, 2015). Overweight and obese women are at increased risk of several pregnancy complications that include abortion, gestational diabetes, hypertension, preeclampsia, thromboembolism, surgical birth, and postpartum weight retention. Despite the serious health implications of obesity in pregnancy, the current level of awareness of such risks among childbearing women is limited (Liat et al., 2015).

Ideally, all women with a BMI greater than 30 kg/m^2 should be provided with accurate and accessible information about the risks associated with obesity in pregnancy at a preconception visit. Weight-loss interventions would be most appropriately used before pregnancy, but if that is not possible, nurses need to recognize the need for opportunistic health promotion aimed at disseminating information about the risks of obesity in pregnancy to overweight and obese women of childbearing age. Most women are highly motivated to have healthy infants, and this could be a key factor in health-promotion discussions that inform women of the risks of obesity in pregnancy and promote healthy lifestyle choices and weight-loss strategies preconceptually and between pregnancies.

Labor and Birth

Pregnancy culminates with labor and giving birth. Giving birth is a life-changing event, and the care that a woman receives during labor

has the potential to affect her both physically and emotionally for a long period. The process of giving birth elicits a significant emotional response from the delivering family. A description of the events of a usual labor and birthing process must occur to establish a background for considering the physiological changes in the mother and the infant.

Several theories offer explanations for the cause of labor. Many factors likely interact, including uterine distention, mechanical irritation, progesterone deprivation, placental aging and hormones, and posterior pituitary activity. Labor usually begins at approximately 40 weeks of gestation, suggesting that hormonal control similar to that regulating the menstrual cycle also contributes to its onset (Cunningham et al., 2014).

Labor may be divided conveniently into the following four distinct stages:

- Dilation stage—lasts from the onset of true labor contractions to complete dilation of the cervix. It is divided into three phases: latent (0–3 cm dilation); active (4–7 cm dilation); and transition (8–10 cm dilation)
- Pushing stage—lasts from complete dilation (10 cm) of the cervix to birth
- Placental stage—lasts from the time of birth of the newborn to delivery of the placenta and membranes, which can range from 2 to 15 minutes
- Recovery stage—defined as the first 4 hours after childbirth, where physiological and psychological adjustments begin to occur

The first stage of labor starts with regular timing of uterine contractions and ends with complete **dilation** (opening) and **cervical effacement** (thinning of the cervix). The signs of beginning labor include those listed in Box 16-2. The cervix, the lower portion of the uterus, must dilate from a closed position (0 cm) to a totally open position (10 cm or 4 in, in diameter). During the first stage the cervix must also completely efface or shorten from a length of 1 to 2 inches to a barely palpable (paper-thin) thickness. For most women, painless

Braxton Hicks contractions throughout pregnancy cause some cervical dilation and thinning, or at least cervical softening, before the onset of active labor.

Box 16-2

Signs of Beginning Labor

- Bloody show or loss of the mucous plug that seals cervical canal during pregnancy
- Regular uterine contractions
- Contractions increasing in intensity, duration, and frequency
- Palpable hardening of the uterus during contractions
- Pain in the lower back radiating to the front of the abdomen

During the **first stage of labor** the presenting part of the fetus begins to press on the cervix, lower uterine segment, and nerve endings around the cervix and vagina. Women's responses to this process differ; pain thresholds and cultural perceptions of and responses to pain differ among laboring women (see Table 16-1). The fundus, the active contractile part of the uterus, becomes thicker as labor progresses, retracts the lower uterine segment and cervix, and helps push the fetus toward the cervix and eventually through the vagina for birth (Macones, 2015). The first stage lasts an average of 8 to 12 hours for women experiencing a first birth and somewhat less for women having a second or additional child. On the basis of a laboring woman's needs, various pain medications, nonpharmacological measures, Lamaze breathing, and other distractive techniques may alleviate the discomfort associated with first-stage labor. Periodic vaginal examinations by the nurse or other health care provider indicate a laboring woman's cervical dilation and effacement and descent of the fetus into the birth canal (a concept

called **station**). In a full-term pregnancy, loss of the amniotic membrane usually increases pressure of the fetal head against the cervix, making dilation and effacement more efficient, and tends to augment the labor process.

During the **second stage of labor** the fetus descends through the lower birth canal toward the woman's perineum. It is the time elapsing from the full cervical dilation to the birth of the newborn. The upper uterine segment greatly thickens, and the abdominal muscles assist in the descent and expulsion of the fetus. Women who have attended childbirth classes are often better prepared to actively push the baby through the pelvis and perineum during contractions. Cultural practices may support pushing from a squatting or upright position and not in a supine one. Nurses must acknowledge that the maternity health care system has a unique culture that may clash with the cultures of many of our care recipients. For many women an overwhelming urge to bear down during uterine contractions occurs at this time. The fetal head accommodates to the mother's pelvis and vaginal structure and, finally, the head becomes flush with the vaginal opening on the woman's perineum. The woman at this point actively pushes to expel the newborn.

The **third stage of labor** begins after the birth of the newborn and lasts until placental expulsion. Placental separation usually occurs within 2 to 30 minutes after completion of the second stage. After delivery of the placenta the health care provider examines the placenta to determine that all placental tissue is intact and to detect any abnormalities that could affect the infant's condition and adaptation to extrauterine life.

The **fourth stage of labor** generally consists of the first 2 hours after childbirth, during which the mother faces the greatest risk of postpartum hemorrhage. An expected blood loss of 250 to 500 mL may cause the mother to experience a moderate decline in blood pressure, but nurses should not wait or rely on this change to intervene (Pavord & Maybury, 2015). The mother may also experience an increase in pulse rate **(tachycardia)** to compensate for blood loss during the early postpartum period. The care plan at the end of this

chapter addresses the nurse's role in managing the **stages of labor**.

Overview of Care

Professional members of the health care team (nurses, midwives, physicians) play an important role in labor and birth, but a woman's family, partner, or significant other (i.e., husband, friend, family) also inherently contributes to her care during labor and birth, particularly in certain cultures (see Table 16-1). Many practitioners suggest that the expectations and beliefs of a birthing couple have a great effect on how the woman fulfills the mothering role. Therefore the nurse needs to collaborate with the people who care for the pregnant woman to meet that family's needs during pregnancy, labor, and childbearing.

With increasing numbers of lesbian/gay/transgender couples getting married, and the availability of alternative methods of conception, these couples are coming in contact more with nurses and health care providers throughout the birthing process (preconception, pregnancy, and postpartum period). Nurses need to have a better understanding of their needs and ways to improve the overall experience for this population. Many challenges that lesbian, gay, bisexual, and transgender couples face include making complex childbearing decisions, navigating a health care system designed for heterosexual couples, and confronting barriers such as health insurance issues and uncertain legal rights. Changes in health care settings to address the needs of this population might include the need to display equality signs, use of gender-neutral language on medical records, in-service education for all health care personnel to confront any heterosexist bias, and discussion of privacy issues throughout the perinatal period (Ellis et al., 2015; Holley & Pasch, 2015).

The importance of the nurse's knowledge, caregiving, and support cannot be underestimated during the first stage of labor. Active emotional and physical nursing support decreases the length of many women's labors, use of analgesics and anesthetics, and number of operative deliveries and may help women reach their birthing goals (Sawant, 2015). Provided that they are accepted by a woman's culture,

independent nursing interventions to increase comfort (e.g., giving backrubs or massages, offering ice or warm fluids by mouth, assisting with ambulation and position changes, and providing a clean and dry environment) may help the laboring woman cope with the challenges of labor. Many women will request medication to diminish the pain of labor and birth, and the nurse may need to review the options for medication with each woman or couple. During the first stage the mother must not bear down, because this may cause cervical swelling; often, active nursing support and distractive techniques, such as breathing and visual refocus, can prevent pushing before the second stage of labor. A woman may depend on the nurse to model breathing techniques to relieve labor discomfort. The nurse may need to explain usual interventions during this stage of labor, including the use of a **fetal heart monitor** (a machine that detects and records fetal heart rate and activity during labor), intravenous fluids, a digital blood pressure machine, and a urinary catheter. Open and clear communication among the health care providers and laboring woman and her significant others, particularly during frequent and difficult uterine contractions, will improve coping before the pushing stage begins.

Contemporary childbearing has benefited from many medical and technical advances, but the current high rate of maternity care interventions may bring about many disadvantages for the healthy majority. Current understanding suggests that safely avoiding unneeded interventions would be wise. Promoting and supporting physiological births, which are low-technology health and wellness approaches to childbearing, would yield better outcomes. Today, physiological childbearing refers to childbearing conforming to healthy biological processes. Evidence-based research reveals that physiological childbearing facilitates better outcomes by promoting fetal readiness for birth and safety during labor, enhances labor effectiveness, provides physiological help with labor stress and pain, promotes maternal and newborn transitions, and optimizes breastfeeding and maternal-infant attachment (Buckley, 2015). Selected physiological principles include limiting use of maternity care interventions, providing prenatal care that reduces stress and

anxiety in women, fostering the physiological onset of labor, not artificial intervention, encouraging hospital admission in active labor, providing privacy and reducing anxiety in labor by continuous support, making nonpharmacological pain measures available, using pharmacological measures sparingly, fostering spontaneously vaginal births, and supporting continuous skin-to-skin contact between the mother and the newborn and early breastfeeding after birth (Lewitt, 2015).

During the second stage of labor the woman needs reassurance and support for her pushing efforts. Constant reinforcement and education by the nurse about labor progress, fetal heart monitor tracings, and other interventions will give the mother and her support system the guidance needed to give birth to the infant. Throughout labor the nurse considers the specific cultural and ethnic needs to support nursing assessment and positive responses to labor by the childbearing family.

Active nursing support during the third and fourth stages of labor includes observing the woman for excessive vaginal bleeding after the placenta has been expelled, assisting the woman in breastfeeding her new baby, monitoring vital signs, and implementing uterine massage if the uterus becomes boggy or fails to contract over the placental site. Emotional support during assessments and delivery of information to explain the rationale for assessments are also important nursing roles supported by professional practice standards.

Current hospital guidelines call for mother-baby dyad care on postpartum units. Nurses must therefore be competent in caring for both populations and be able to share a large amount of information in a short time (typically 1–3 days) to prepare mothers for discharge. Although teaching and support related to breastfeeding take priority, other topics nurses must address before discharge include bathing, car seat safety, jaundice, safe sleep, postpartum mood disorders, and nutrition for both the mother and the baby. Having a standard discharge checklist and pamphlets to give the mother to read will help nurses ensure a successful transition from the hospital to the home.

Throughout the entire labor and birth process, the nurse carefully

observes the laboring woman and fetus so that she can detect early any difficulties with the progress of labor or with maternal or fetal health. Problems may include unusual fetal or uterine activity, the presence of **meconium** (fetal stool) in the amniotic fluid, fetal tachycardia (heart rate greater than 160 beats per minute) or fetal **bradycardia** (heart rate less than 110 beats per minute) in a full-term infant, and fetal heart rate decreases with uterine activity during labor (Mattson & Smith, 2015). These events must be reported immediately to the health care provider, with a complete oral and electronic description of the event. The nurse must be aware that abnormal fetal and maternal signs and patterns may be related to factors such as maternal diabetes or hypertension; the type, timing, or dosage of labor medications; uterine contraction pattern; maternal or fetal infections; maternal anemia; preeclampsia; the presence and character of amniotic fluid; bleeding in the pregnant woman or fetus; or early gestational age of the infant (Spong, 2015).

Our major role as nurses is to provide safe and evidence-based care to promote optimal birth outcomes for all women. Nurses need to remember there is more than one way to provide this care. Nurses are educated to assess every woman as an individual and to plan care with mutual goal setting for the best outcomes. By assisting all people seeking care from diverse cultures and by adopting our practices as much as possible to embrace the cultural traditions of others, we will enhance the childbearing experience and promote the health of women, newborns, and families.

Changes During Transition From Fetus to Newborn

Most newborns experience a smooth transition from intrauterine to extrauterine life. The fetus to newborn transition is complex and depends on several factors, including maternal health and chronic medical conditions, the status of the placenta, gestational duration, the presence of fetal anomalies, and birthing room care. When difficulty occurs, however, the newborn's viability depends on the nurse's understanding of the fine balance of chemical, physiological, and anatomical changes that occurs as it makes the transition to postnatal life (Swanson & Sinkin, 2015).

Nursing Interventions

Nursing activities during this adaptation process include assessment and interventions aimed at specific protection of the infant and prevention of complications. Cold stress should be avoided by the newborn being kept dry and warmly wrapped and by avoidance of environments that cause heat loss. Overall, the nurse should minimally disturb, but maximally observe and document, the newborn's behavior during reactive periods.

Apgar Score

Assessment of the newborn after the first few hours of life is essentially the same as assessment of the young infant (see Chapter 17). One technique, specific to timing after birth, is the **Apgar scoring system**. This scoring system has historically been used to provide a simple clinical measure to evaluate the newborn's general condition at birth. The Apgar score, obtained at 1 and 5 minutes of age, may be obtained again at 10 minutes of age until the infant's condition has stabilized. A total score is calculated by addition of the values allotted to the categories noted in Table 16-3. The highest possible score is 10.

A score of 8 to 10 indicates that the baby is adapting well. The Apgar score does not predict the neurological development of an infant but may relate to the infant's risk of illness or death during the first year of life, which is important information for parents of an infant with a low Apgar score (Apgar, 2015).

TABLE 16-3

Apgar Scoring

SIGN	SCORE		
	0	1	2
Heart rate	Absent	Slow (<100)	>100
Respiratory effort	Absent	Weak cry, hypoventilation	Good strong cry
Muscle tone	Flaccid, limp	Some flexion of extremities	Active motion, extremities well flexed
Reflex irritability	No response	Grimace	Cry
Color	Blue, pale	Body pink, extremities blue	Completely pink

Sex

Sex differences occur in fetal growth. Generally, boys grow faster than girls in the third trimester, and at birth boys are slightly heavier, are longer, and have a larger head circumference than girls (Lissauer et al., 2015). Although more boys are conceived, they tend to be aborted spontaneously more often than girl embryos; the two X chromosomes possessed by female embryos may protect them from the early hazards of pregnancy. After birth, boys continue to have a lower survival rate than do girls (Stevenson et al., 2015).

Race and Culture

Race may affect the health of the fetus in several ways. For example, in the United States, nonwhites (mainly blacks) have more fraternal twin pregnancies than whites (Cunningham et al., 2014). Because their

organs are less mature, twin fetuses face an increased risk of **premature delivery** as a result of gestational factors in the mother. Currently the United States is 49th in the world ranking for **infant mortality rate (IMR)**, with a rate of 5.87 per 1000 live births (Central Intelligence Agency, 2015). This rate reflects the number of infants who die before the end of their first year of life and is the leading indicator of a nation's health. It reveals the higher IMRs and low-birth-weight outcomes of blacks, American Indians, and other ethnic minority populations in the United States. This rate illustrates the complex sociopolitical issues that produce birth outcomes in the United States and those needing attention to reduce the IMR (US Department of Health and Human Services [USDHHS], Office of Minority Health, 2015; CDC, 2015b).

Race is also a factor in the frequency of certain genetic and congenital malformations (Box 16-3: Genomics). For example, more babies of Native American, Latino, or Asian descent have cleft palates (an opening in the oral palate) than do black babies (Tewfik et al., 2015). Black babies have higher rates of sickle cell anemia (abnormally shaped red blood cells) than white babies. The total proportion of malformations tends to be approximately the same in all races that have been studied (whites, blacks, Hispanics, and Asians) (March of Dimes, 2015).

Box 16-3

Genomics

Genetic Testing May Lead to Ethical Dilemmas

Prenatal genetic testing provides important opportunities for assessment of genetic risk and diagnosis. However, some genetic tests do not identify all the possible gene mutations that can cause a particular condition, or they have limited predictive value. Because some genetic tests may not provide all the information that families may want, the test may subsequently require difficult decisions without providing full information. As an example, a cystic fibrosis

carrier test can identify couples who are both carriers. When the cystic fibrosis mutations are identified in the parents, prenatal diagnosis can be performed to determine whether a fetus has inherited a cystic fibrosis gene mutation from each parent. Knowing that a fetus has inherited two cystic fibrosis mutations, however, does not, at this time, predict the severity of the disease in the infant. For couples in this situation, the ethical dilemma involves the decision to continue or to end a pregnancy without having knowledge of the severity of the disorder.

Should the Information Be Obtained if No Treatment or Intervention Exists?

Genetic testing can lead to specific treatments or interventions for some conditions but not for others. This is the case with some disorders that can be detected in expanded newborn screening. When phenylketonuria is identified, dietary intervention allows individuals with this condition to lead healthy and productive lives. Currently, however, not all conditions can be adequately treated. Genetic testing for some conditions for which there are no treatments might have the potential to cause psychological harm, stigmatization, and discrimination. Genetic testing for Huntington disease, a progressive motor and cognitive disorder with onset in midlife, is one example. There are no effective treatments or preventive measures currently available. Thus choosing to have genetic testing for Huntington disease is highly personal, and it is recommended that individuals consider extensive pretest counseling. These tests may lead to decisions that cannot be reversed and are based on a woman's best guess as to what would be the best course of action for her and her family. The dilemma that occurs then is whether a newborn should be tested for disorders that we cannot treat.

Ethical decision-making models/frameworks are valuable tools that can assist nurses in addressing ethical dilemmas. Principles of autonomy, informed consent, privacy/confidentiality, beneficence, nonmaleficence, and justice are applicable to use in the ethics involved in genetic testing. These principles should be sensitive to

human needs, should be responsive to contextual considerations, and should emphasize the uniqueness of each situation.

- What might be the nurse's role in assisting the family in the decision-making process?
- What assurances can be made regarding privacy and confidentiality of the genetic information to prevent future employment or health insurance discrimination?
- What resources are available to nurses to keep current on prenatal genetic testing?

A woman's ethnic background may also influence the health of her fetus on the basis of a link to socioeconomic status. For increasing numbers of homeless pregnant women, income may support family survival needs but not prenatal care. Minority group pregnant women may have fewer economic resources to obtain a nutritious diet or early and consistent high-quality prenatal care. These outcomes may relate to access to health care factors or cultural beliefs that do not support recommended foods or prenatal care (Box 16-4: *Healthy People 2020*).

Box 16-4

Healthy People 2020

Selected National Health-Promotion and Disease-Prevention Objectives for the Prenatal Period

- MICH-1.1: Reduce the rate of fetal deaths at 20 or more weeks of gestation to no more than 5.6 per 1000 live births. (Baseline: 6.2 per 1000 live births in 2005; target, 5.6 deaths per 1000 live births and fetal deaths in 2020—10% reduction.)
- MICH-1.2: Reduce the rate of fetal and infant deaths during the perinatal period (28 weeks of gestation to 7 days after birth) to no

more than 5.9 per 1000 live births. (Baseline: 6.6 per 1000 live births in 2005—10% reduction.)

- MICH-1.4: Reduce the rate of neonatal deaths (within the first 28 days of life) to 4.1 per 1000 live births. (Baseline: 4.5 per 1000 live births in 2006—10% reduction.)

- MICH-5: Reduce the rate of maternal deaths to 11.4 maternal deaths per 100,000 live births. (Baseline: 12.7 per 100,000 live births in 2007—10% reduction.)

- MICH-6: Reduce the rate of maternal illness and complications due to pregnancy (complications during hospitalized labor and birth) to 28%. (Baseline: 31.1% of pregnant women experienced complications during hospitalized labor and delivery in 2007—10% reduction.)

- MICH-7.1: Reduce the rate of cesarean births among low-risk (full-term, singleton, vertex presentation) women to 23.9%. (Baseline: 26.5% of low-risk women giving birth for the first time had a cesarean birth in 2007—10% reduction.)

- MICH-8.1: Reduce the rate of low-birth-weight newborns to 7.8%. (Baseline: 8.2% of live births were low-birth-weight births in 2007.)

- MICH-8.2: Reduce the rate of very low-birth-weight newborns to 1.4%. (Baseline: 1.5% of live births were very low-birth-weight births in 2007.)

- MICH-9.1: Reduce the rate of total preterm births to 11.4%. (Baseline: 12.7% of live births were preterm births in 2007—10% reduction.)

- MICH-9.2: Reduce the rate of late preterm births or live births at 34 to 36 weeks of gestation to 8.1%. (Baseline: 9.0% of live births were late preterm births or occurred at 34 to 36 weeks of gestation in 2007—10% reduction.)

- MICH-10.2: Increase the proportion of pregnant women who receive early and adequate prenatal care to 77.6%. (Baseline: 70.5% of pregnant women received early and adequate prenatal care in 2007—10% increase.)

- MICH-11: Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women to 98.3% for alcohol, 98.6% for cigarette smoking, and 100% for illicit drugs. (Baselines: 89.4% of pregnant females aged 15 to 44 years reported abstaining from alcohol in the previous 30 days in 2007–08; 89.6% of females delivering a live birth reported abstaining from smoking cigarettes during pregnancy in 2007; and 94.8% of pregnant females aged 15 to 44 years reported abstaining from illicit drugs in the previous 30 days in 2007–08—10% increase.)

- MICH-14: Increase the proportion of women of childbirth potential with intake of at least 400 mcg of folic acid from fortified foods or dietary supplements to 26.2%. (Baseline: 23.8% of nonpregnant females aged 15 to 44 years reported a usual daily total intake of at least 400 mcg of folic acid from fortified foods or dietary supplements in 2003–06—10% increase.)

- MICH-16: Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health behaviors to following values: 33.1% for taking vitamins prenatally; 85.4% for not smoking cigarettes before pregnancy; 56.4% for not drinking alcohol before pregnancy; and 53.4% for maintaining a healthy weight before pregnancy. (Baselines: 30.1% of women delivering a recent live birth took multivitamins/folic acid every day in the month before pregnancy as reported in 2007; 77.6% of women delivering a recent live birth did not smoke in the 3 months before pregnancy as reported in 2007; 51.3% of women delivering a recent live birth did not drink alcohol in the 3 months before pregnancy as reported in 2007; and 48.5% of women delivering a recent live birth had a normal weight [i.e., a BMI of 18.5–24.9 g/m^2] before pregnancy as

reported in 2007—10% increase.)

Genetics

The science of genetics has expanded recently to genomics (the science that studies genes that make up the human genome). The completion of the mapping and sequencing of the human genome led to the expansion of research technologies that are now used to identify genetic and genomic factors that have an influence on people's health. Genetic influences affect the survival and later well-being of the child through several known mechanisms. **Down syndrome** (trisomy 21) remains the most recognized and most commonly occurring example of an extra chromosome. Extra chromosomes, deleted chromosomes, or translocations usually cause multiple malformations incompatible with life, causing early loss of the fetus via **spontaneous abortion**. Single malformations in an otherwise normal fetus (e.g., clubfoot, cleft palate, or NTD) probably result from a combined effect of many genes (March of Dimes, 2015). These defects, found at birth, may be surgically corrected or managed during the child's life. Invasive techniques of **amniocentesis**, chorionic villus sampling, and chromosome analysis have expanded genetic counseling options and interventions for women facing possible fetal genetic defects. Nurses now will have to deal with the challenges of the explosion of genomic information to provide personalized health care based on genomics. The nurse, as a vital member of the health care team, needs to assist in informing these women and couples of genetic and high-risk screening resources when family history or other factors indicate that a fetal genetic defect may be likely.

Gordon's Functional Health Patterns

Box 16-5 provides an example of a pregnancy assessment using Gordon's (2016) functional health patterns.

Box 16-5

Assessment for Pregnancy According to Gordon's Functional Health Patterns

Health perception–health management pattern: Aware of or participates in management of pregnancy, or both; expects an uncomplicated pregnancy on the basis of the woman's or significant other's active involvement in her own care; able to state complications of pregnancy that mandate physician notification; engages in health-promotion behaviors specific to pregnancy.

Nutritional-metabolic pattern: Follows diet changes of pregnancy as recommended by nurse; has appropriate weight for height and has gained adequate weight for gestational age of pregnancy; eats three meals a day and two snacks (afternoon and evening), focusing on increased amounts of vegetables and fruits; drinks healthy fluids, including at least eight glasses of water per day; has elastic skin turgor.

Elimination pattern: Experiences occasional constipation from progesterone influence of gastrointestinal peristalsis relaxation, usually corrected by increased fluids, nightly walking, and more diet roughage; voids 7 to 10 times a day, depending on amount of fluids consumed; no known hemorrhoids or difficulty in elimination; voiding without excess frequency, urgency, or burning; understands signs of UTI.

Activity-exercise pattern: Walks three times a week for 20 minutes

without reports of unusual fatigue or soreness; active at home with housework and at work teaching in a primary school; swam two times a week before pregnancy and moved to current residence.

Sleep-rest pattern: Generally, sleeps 7 to 8 hours a night; has increased total daily sleep somewhat with fatigue of pregnancy—naps for 1 hour on weekends and 30 minutes after work; sleeps on side and with two pillows for comfort; uses no sleep aids; generally able to relax and initiate sleep without difficulty; occasionally has headache at end of workday and takes acetaminophen (Tylenol) for relief or listens to soft music after work to enhance relaxation.

Cognitive-perceptual pattern: Realizes the need to decrease work activity and increase rest periods as she nears end of pregnancy; answers questions in appropriate tone and words during pregnancy visits; has intact memory (alert and remote); reads about pregnancy and early parenthood to prepare for the birth.

Self-perception–self-concept pattern: States she is excited about pregnancy after 1 year of trying to conceive; well groomed, wears maternity clothes because "I want to"; believes she looks "nice" because of pregnancy.

Roles-relationships pattern: Lives with husband of 3 years; visits extended family, 60 miles away, every month; shares family roles with husband, accepts this balance; has many friends who support her pregnancy; perceives extensive employee and employer support with pregnancy and time off after delivery.

Sexuality-reproductive pattern: States, "I have a satisfying love life and enjoy my husband"; before pregnancy, engaged in sexual intercourse four to five times a week with desire to become pregnant; with pregnancy and fatigue, has intercourse generally two to three times a week, with pattern acceptable to both partners; no known STIs in past or present.

Coping–stress tolerance pattern: Concerned about fatigue affecting performance as primary school teacher; walks three times a week for 20 minutes to "center myself and feel good"; smiles often, good sense of humor; supportive family excited about her pregnancy.

Values-beliefs pattern: Protestant religion; prays daily and gains strength from religion.

Other data:

- Medication history:

Prenatal vitamin, one tablet each morning

Ferrous sulfate, one tablet each morning

Acetaminophen (Tylenol) 650 mg for occasional headaches

- Physical examination:

5 feet, 4 inches tall

Weight 140 lb (at 14 weeks of pregnancy; weight gain of 5 lb with pregnancy)

29 years of age

Pupils equally round and reactive to light and accommodation

Temperature 98.2°F; pulse 76 beats per minute; respiration 16 breaths per minute

Blood pressure 114/78 mmHg right arm (sitting, left arm)

Peripheral pulses equal, strong bilaterally

Skin warm, dry, elastic turgor; mucous membranes intact, moist; alert, oriented

Modified from Gordon, M. (2010). *Manual of nursing diagnosis* (12th ed.). Sudbury, MA: Jones & Bartlett Learning; Peterson, R. (2012). *Clinical companion for fundamentals of nursing* (8th ed.). St. Louis: Mosby.

Health Perception–Health Management Pattern

On the basis of her culture and life experience, a woman may view pregnancy as an illness, as a completely natural and healthy state, or as a combination of the two. This perception will influence her view of her changing body, her attitude toward the usual discomforts of pregnancy such as fatigue or backache, her choice of health-oriented or illness-oriented care, and her decision to seek prenatal care. The woman who sees herself as healthy and pregnancy as a normal part of her life most likely will seek a health care provider with a similar outlook. Another woman with the same perception may seek help from a socially approved group, as defined by her culture, and avoid standard Western medicine during pregnancy (e.g., Roma [gypsies]). Generally, women with a positive view of pregnancy will continue with active participation in their respective social circles and careers. However, the woman who sees her pregnancy as a time of illness may use this as a reason to withdraw from her work and social obligations.

A woman's acceptance of her pregnancy influences her health-management practices and choices. The woman who denies or has

strong negative feelings about her pregnancy may fail to eat properly, get enough rest and exercise, breastfeed, or seek prenatal care. A woman may deny a pregnancy because she never intended to become pregnant despite having sexual intercourse without birth control. Approximately 50% of American pregnancies are unintended, particularly among vulnerable aggregates such as adolescents, women older than 40 years, women with low income, and women who lack health care access, cultural acceptance, and education, experience sexual violence, and lack financial resources to purchase or use contraceptives. A decrease in the unintended pregnancy rate by 30% was promoted as one of the first *Healthy People* goals in 2000, but has been changed to a more modest 7% reduction rate in *Healthy People 2020* (Hewitt & Cappiello, 2015; USDHHS, 2010). These women, faced with an unplanned or a closely spaced pregnancy, may expose a fetus to alcohol, tobacco, and **sexually transmitted infections** (STIs), abuse a child who was never wanted, or fail to obtain follow-up care for a high-risk child (i.e., experienced complications from childbirth) (USDHHS, 2010; US Preventive Services Task Force, 2015a).

Nurses encounter women with reproductive health needs and concerns in all practice settings and play an important role in caring for them as an integral member of the health care team. The nurse who works with a pregnant population must be sensitive to a wide range of views expressed by these women and work with each to effectively manage their pregnancies. For example, Hispanic women are less likely to receive early prenatal care because of a belief that pregnancy is not an illness. The nurse targets interventions that focus on this group's needs and beliefs while adhering to professional practice standards that will improve their outcomes.

Nutritional-Metabolic Pattern

A woman's nutritional status should be assessed preconceptually with the goal of optimizing maternal and fetal health. Pregnancy-related dietary changes should begin before conception, with needed modifications during pregnancy and lactation. Most nutritional requirements of pregnant and lactating women can be met by their

consuming a variety of foods according to government-endorsed guidelines. Massive amounts of literature support the importance of optimal nutrition during pregnancy for maternal and fetal well-being. The key components of nutritional management during pregnancy include consumption of a variety of foods, appropriate weight gain, appropriate micronutrient supplementation, physical activity, and avoidance of alcohol, tobacco, and other harmful substances. Maternal malnutrition before and during pregnancy may exert a teratogenic effect on the fetus. A **teratogen** is an agent that causes either a functional or a structural disability in the organism as a result of exposure to that agent (Merriam-Webster, 2015). Teratogens principally affect the central nervous system of the fetus, leading to impaired intelligence and performance later in life. They are discussed more in the Environmental Processes section later in the chapter.

Various factors influence the quality of nutrition needed for positive fetal development and birth outcome. Fetal development suffers in cases of adolescent pregnancy or in pregnancies of older women who experience poor nutrition between and during several pregnancies. Maternal nutritional deficiencies during a woman's own fetal, infant, and childhood periods also contribute to the development of structural and physiological disadvantages to supporting a growing fetus. For example, women who are severely underweight before pregnancy often experience higher rates of low-birth-weight infants and preterm labor than do women of appropriate prepregnant weight (Cunningham et al., 2014). Inherited maternal stature and pelvic development may influence pregnancy and efficiency of labor and delivery. A lack of income to buy healthy food may also exist, and sometimes cultural values related to food intake influence the quality of nutrition during pregnancy.

To meet increased metabolic, energy, and structural needs for pregnancy, most nutritionists recommend that a pregnant woman increase her intake by approximately 300 calories each day (USDHHS, 2010). This results in a total weight gain of approximately 25 to 35 pounds (Figure 16-3). If at the end of 20 weeks of gestation the woman has not gained at least 10 pounds, she risks delivering an ill infant

with fetal growth restriction. This risk also exists when a woman continues to gain insufficient weight throughout the pregnancy or in a woman who was underweight or overweight before pregnancy. Although the rate of gain and the total gain during pregnancy differ among women, a correlation exists between an erratic pattern of weight gain or a too-rapid weight gain and a lack of fetal well-being (Bier et al., 2015). The nurse advises the pregnant woman to eat a well-balanced diet.

FIGURE 16-3 Many practitioners recommend a weight gain of 25 to 35 pounds for women at normal weight for their height.

A well-balanced diet for a pregnant woman parallels that needed by all human beings, with increases in the amounts of certain components as recommended by the Food and Nutrition Board of the National Academy of Science (IOM, 2015; USDHHS, 2010). The nurse recommends that the entire family eat a healthy diet. The nurse encourages the pregnant woman to drink 8 to 10 glasses of water per day to develop amniotic fluid and prevent urinary tract infections (UTIs) often seen with pregnancy. The nurse may also need to encourage the woman to modify her diet to include more fiber and roughage to avoid constipation during pregnancy (Table 16-4).

TABLE 16-4

Nutritional Needs for Pregnant and Lactating Women

Nutrient	Pregnancy	Lactation	Sources	Comments
Calories	+300	+500	Eat a variety from all food groups	Begin to increase calories in second and third trimesters
Protein	70 g	70 g	Lean meat, fish, eggs, poultry, milk, and dairy products	Supports fetal growth and development; formation of placenta and amniotic fluid; and expanded blood volume
Calcium	1000 mg/day	1000 mg/day	Milk, cheese, dark green leafy vegetables, nuts, and dried fruit	Women with low calcium intake require calcium supplements with vitamin D
Iron	27 mg/day	9 mg/day	Lean meats, dark green leafy vegetables, eggs, whole grain, dried fruit, and shellfish	Provides iron for fetal liver storage, which sustains infant for first 4–6 months of life
Folic acid	600 mcg	500 mcg	Fresh green leafy vegetables, liver, peanuts, whole-grain breads, and cereals	All women of childbearing age should take 400 mcg of folic acid daily to prevent neural tube defects in first trimester
Fats	30% of daily calories	30% of daily calories	Low-fat dairy products and lean cuts of meat	Provide a valuable source of energy for the body during pregnancy
Carbohydrates	7–11 servings daily	7–11 servings daily	Dairy products, fruits, vegetables, whole-grain cereals, and breads	Provide fiber necessary for proper bowel functioning. Carbohydrate intake needs to be sufficient to prevent ketoacidosis from protein use for energy

From Thompson, J., & Manore, M. (2012). *Nutrition: An applied approach* (3rd ed.). San Francisco: Benjamin Cummings.

Protein requirements during pregnancy increase to approximately 70 g per day, or a daily increase of 25 g above normal (Whitney & Rolfes, 2015). This ensures an adequate supply of amino acids for fetal growth and development, blood volume expansion, and maternal tissue growth. Other protein sources, such as cheese, cream soups, puddings, tofu, and yogurt, may be better tolerated by some women and by those from cultures (Hispanic) that do not drink milk. Animal protein and less expensive legume sources provide protein and, if combined with other healthy food sources, provide high-quality meals (e.g., tuna and rice, peanut butter, and whole-wheat bread). Protein foods cost more than other foods; therefore the nurse may need to teach pregnant couples about economical ways to meet protein needs for fetal development.

Mineral intake must also increase during pregnancy. Increased

protein intake usually provides the extra needed essential minerals, particularly phosphorus and calcium. The rapid deposit of calcium in fetal bones and teeth during the third trimester of pregnancy requires adequate maternal calcium stores from early pregnancy and continued calcium intake to prevent maternal bone demineralization. Other calcium sources include green, leafy vegetables and calcium-fortified foods, sources more acceptable to cultures with a history of lactose intolerance (African, Mexican, and some European groups).

Sufficient iodine intake by pregnant and lactating women is crucial for thyroid hormone production, which contributes to the offspring's neurocognitive development. Approximately one-third of pregnant women are marginally deficient in iodine. The American Academy of Pediatrics calls for pregnant and lactating women to use iodized salt and take a supplement of 150 mcg of iodine daily, which typically is not contained in prenatal vitamins. As processed and convenient foods make up a large portion of American diets today, women need to be informed that the salt used in them is not iodized (American Academy of Pediatrics, 2014).

A woman who eats a well-balanced diet should gain sufficient vitamins and minerals for maternal and fetal needs during pregnancy. However, most health care providers recommend that the pregnant woman include 30 mg of elemental iron daily to benefit both herself and the fetus, particularly during the last trimester. **Anemia of pregnancy** is a global health problem affecting nearly half of all pregnant women worldwide. High fetal demands for iron, increased erythrocyte mass, and in the third trimester, expanded maternal blood volume render iron deficiency the most common cause of anemia of pregnancy. In certain geographical populations, human pathogens such as hookworm, malarial parasite, and HIV are important factors contributing to anemia of pregnancy. The hemoglobinopathies—sickle cell disease and thalassemia—represent diverse causes of anemia of pregnancy, requiring specialized care. Iron-deficiency anemia is common among pregnant women, and anemia contributes to hemorrhage, postpartum infection, and **preterm birth**. Anemia occurs more often among pregnant adolescent, black, and older white

women (Cantor et al., 2015).

There are almost universal recommendations for periconceptual folic acid supplementation to prevent NTDs. NTDs are congenital malformations that include anencephaly, encephalocele, and spina bifida caused by the failure of fusion of the neural tube, which normally closes between the 22nd and 28th days after conception (at an average of 40–42 days after the first day of the last menstrual period). The occurrence of NTDs differs among the population, ranging between 0.8 per 1000 births and 3 per 1000 births, and it is estimated that more than 300,000 pregnancies are affected every year worldwide. According to the World Health Organization (WHO), increased consumption of folic acid can decrease the risk of NTD to 0.6 per 1000 births (Cordero et al., 2015). To decrease the risk of NTD, it is recommended that all women capable of becoming pregnant should consume more folic acid. The goal is that every woman could start her pregnancy with an optimal folate status. Evidence-based research thus supports that women planning pregnancy and those in their first trimester take 0.4 mg of folic acid in a daily multivitamin supplement to prevent NTDs and anemia. This is particularly important for women with multiple gestations, who experience a greater risk of anemia. However, research has shown that only 25% of women of childbearing age consume the recommended amount of folic acid, which is critical for early fetal development (USDHHS, 2010).

Fats and carbohydrates must supply the caloric requirements during pregnancy. Although increased protein intake provides more calories, the body-building requirements of pregnancy and fetal growth demand most of the added protein. Fats and carbohydrates remain the most important sources of energy and essential vitamins and minerals. Supplemental vitamins and minerals, although not known to cause maternal or fetal harm if taken in reasonable doses, probably cost the pregnant woman more to meet the nutritional needs of pregnancy than does a well-balanced diet.

The practice of **pica**, a psychobehavioral disorder characterized by the ingestion of nonfood substances such as dirt, clay, laundry starch,

ashes, plaster, raw rice, paint chips, coffee grounds, and ice, may negatively influence the quality of a pregnant woman's nutrition during pregnancy. No one knows what causes these cravings, but a combination of biochemical, psychological, and cultural factors may be at work. Pica in humans can be classified by the type of ingested substance. The three main substances consumed by pregnant women are soil or clay (geophagia), ice (pagophagia), and laundry or corn starch (amylophagia). Other pica cravings include burned matches, stones, charcoal, mothballs, soap, sand, plaster, coffee grounds, baking soda, paint chips, and glue (Jyothi, 2015). Common in rural pregnant black women, this practice may contribute to iron-deficiency anemia and interfere with nutrient absorption, particularly among women of lower economic status. Other potential complications may include lead poisoning, fecal impaction, gastrointestinal reflux, parasitic infections, prematurity, perinatal death, low-birth-weight infants, and anemia in the infant (Miao et al., 2015). Pica is often practiced by black American women, usually in the rural southern United States. It is thought to occur as a result of an iron deficiency that leads to the craving and/or a carryover from behaviors practiced in Africa (Mattson & Smith, 2015). The nurse completes a nutritional assessment on any pregnant woman. The nurse identifies instances of pica and suggests a culturally sensitive diet that will better meet the needs of the woman and her developing fetus. It is essential that the nurse remain nonjudgmental but stress the importance of an adequate diet, folic acid, iodine, and iron supplements, and the dangers of pica.

The best time to teach a woman about prenatal nutrition is before she becomes pregnant. Most women do not seek prenatal care until they suspect pregnancy. Therefore the nurse often delivers information about optimal nutrition to the pregnant woman after critical fetal development has already begun. If all schoolchildren received nutrition information as part of their kindergarten through 12th grade curriculum (a primary prevention approach), women might have better overall personal nutrition established through lifestyle practices of individuals and families that would support high-quality prenatal nutrition later in their lives. Without such a primary

prevention approach, secondary prevention intervention during pregnancy occurs through laboratory monitoring of iron levels, assessment of the woman's feelings of well-being, determination of the woman's actual intake of essential nutrients, and assessment of her pattern and total weight gain during the pregnancy. Many pregnant women work outside the home and may be among the increasing numbers of American families who spend 40% of their food budgets on food eaten outside the home (USDHHS, 2010). The nurse alerts the pregnant woman and her family to the documented high amounts of cholesterol, calories, sodium, and fat and low amounts of iron and calcium that these foods contain so as to improve nutritional intake during pregnancy.

In June 2011, the US Department of Agriculture (USDA) unveiled a new food icon, MyPlate, which replaces MyPyramid as the government's primary food group symbol. MyPlate is meant to serve as a simple guide to help consumers choose healthful foods. To build a "healthy plate," MyPlate suggests that consumers choose fruits, vegetables, whole grains, low-fat dairy products, and lean protein foods to get essential nutrients without excess calories. The strategies for creating such a plate include filling half your plate with fruits and vegetables, using whole grains for at least half of your daily grains consumed (e.g., 100% whole-grain cereals, breads, and pasta), switching from whole milk to skim or 1% milk, and choosing a variety of protein sources (e.g., seafood, small portions of lean meat and poultry, and beans). It also recommends that women should avoid shark, swordfish, king mackerel, or tilefish when they are pregnant or breastfeeding. These fish contain high levels of mercury and should be avoided. In summary, the pregnant woman needs to follow the USDA Daily Food Plans for Moms as follows:

- Fruits and vegetables—seven or more servings daily (three servings of fruit and four of vegetables)
- Whole-grain or enriched breads/cereals—six to nine servings daily
- Dairy products—three to four servings of low-fat or nonfat milk, yogurt, or cheese daily
- Meat and beans—three servings daily (one serving is equivalent to 2

ounces) (USDA, 2015).

See Chapter 11 for more information on nutrition, including MyPlate.

Elimination Pattern

Fetus

The fetus accomplishes all essential elimination functions through the placenta. Carbon dioxide, water, urea, and other waste products pass through the placenta, to be eliminated by the mother's body. By the end of the first trimester, the fetus swallows, makes respiratory movements, and urinates. However, these abilities become truly functional only after birth.

Pregnant Woman

The pregnant woman experiences changes in her elimination pattern because of the enlarging uterus and hormonal influences. These changes (urinary frequency during the first and third trimesters, constipation, and hemorrhoids) cause normal, minor discomforts. Anticipatory guidance by the nurse helps the pregnant woman cope with these changes and prevent complications of pregnancy. For example, teaching the pregnant woman commonsense measures (Box 16-6: Innovative Practice) may prevent UTIs, typically a problem that is more common during pregnancy. With a known correlation between UTIs and premature labor, a focus on preventing and managing these infections must occur during pregnancy.

Box 16-6

Innovative Practice

Evidence-Based Practice for Preventing Urinary Tract Infections and Promoting Genitourinary Health

- Increase fluid intake to approximately 8 to 10 glasses per day; plain water is best to flush the body's systems of potential toxins; drink a glass of water before sexual intercourse to allow urinary output afterward to prevent UTIs.
- Avoid bladder irritants such as caffeine products, alcohol, artificial sweeteners, spicy foods, and carbonated beverages.
- Make urination a regular habit; avoid waiting to urinate until bladder is full.
- Urinate before and after sexual intercourse to cleanse the urethra and empty the bladder.
- Be aware that vigorous or frequent intercourse may contribute to increased risk of UTIs.
- Maintain consistently good perineal hygiene, including wiping from front to back after urination and defecation.
- Take all prescription medications given for UTIs, even when the symptoms of the infection have been alleviated.
- Drink cranberry juice to acidify the urine or take cranberry pills; these products may relieve some of the symptoms of a UTI. Cranberry *(Vaccinium macrocarpon)* has demonstrated antiinflammatory, antiadhesive, and antioxidant properties.
- Seek health care advice for a vaginal infection, which may contribute to development of a UTI.
- Nurses need to be aware that most UTIs are caused by *Escherichia coli*, and most women may be asymptomatic. Obtaining a urine specimen and culture is needed with any degree of suspicion of a UTI.
- Approximately half of UTIs in pregnancy occur in women with

preexisting asymptomatic bacteriuria, and these UTIs have poor outcomes, including preterm rupture of membranes, preterm birth, neonatal infection, preeclampsia, maternal anemia, amnionitis, and maternal septic shock.

- The nurse should assess the woman for increased risk of developing a UTI: congenital or structural abnormalities of the genitourinary system, previous surgery to the genitourinary system; pregnancy; previous UTIs; high intake of carbonated beverages; and poor intake of water.

From Matuszkiewicz-Rowińska, J., Małyszko, J., & Wieliczko, M. (2015). Urinary tract infections in pregnancy: Old and new unresolved diagnostic and therapeutic problems. *Archives of Medical Science, 11*(1), 67–77; Sheerin, N. S. (2015). Urinary tract infection. *Medicine, 43*(8), 435–439.

Activity-Exercise Pattern

Fetus

Early spontaneous movements of the fetus may be reflexive, stimulated by passive uterine movement. Ultrasonographic observation of fetal movement shows repetitive movements early in pregnancy; at approximately 16 weeks, the pregnant woman feels these movements, termed **quickening**. By the end of the second trimester, fetal movement occurs less frequently because of lack of space in the uterus. The woman and her partner look forward to the regular daily cycle of movements, indicators of fetal well-being. An absence of or a dramatic increase in fetal movements for more than 8 hours may indicate fetal distress. The nurse routinely teaches a pregnant woman to count the number of fetal movements each day typically starting at 28 weeks' gestation and report any decrease in fetal activity to the health care provider.

Pregnant Woman

The physical changes during pregnancy and the rigors of labor and delivery require that a pregnant woman be in the best physical

condition of her life. Fortunately, many pregnant women view pregnancy as a normal, natural state, and they often participate actively in physical activities or sports enjoyed before pregnancy. Generally, a woman should avoid high-risk sports, such as sky diving and high-altitude climbing, because these could cause trauma to the fetus from low oxygen pressure or a maternal fall. Nurses encourage each woman to choose activities on the basis of her interests, comfort, and good judgment. When a sport or activity causes exhaustion or pain, it should be modified or discontinued. Later in pregnancy the woman should be encouraged to choose safe physical activities because of changes in her center of gravity attributable to the enlarging uterus and in the musculoskeletal system.

The woman with a sedentary lifestyle before pregnancy should slowly increase her activity level during pregnancy. A daily swim or 30-minute walk provides a good introduction to a regular exercise program. Regular exercise contributes to joint flexibility, increased cardiovascular and gastrointestinal fitness, decreased uterine tone for an efficient labor, fewer pregnancy discomforts, weight control and a lower risk of diabetes by maintaining glycemic control, and overall feelings of well-being in the pregnant woman (USDHHS, 2010). For the self-directed woman, prenatal classes or a consumer-oriented book of prenatal exercises will facilitate an adequate exercise program. For most women, group exercise with other pregnant women is more enjoyable than exercising alone. The benefits of physical activity in the general population are established, and research suggests regular physical activity following childbirth is linked to improved health outcomes. However, many women do not resume prepregnancy exercise levels. The nurse encourages women to enter a structured diet and exercise program sponsored by the birthing hospital to help women lose weight after childbirth (Spencer et al., 2015).

In an uncomplicated pregnancy, a couple may continue their usual sexual activity. However, threatened abortion or a history of abortion in the first trimester, early rupture of membranes, and other complications may call for restrictions on sexual intercourse or orgasm.

Sleep-Rest Pattern

Fetus

Electroencephalographic studies have shown four cyclical states of activity in the fetus: complete wakefulness, drowsy wakefulness, rapid eye movement sleep, and quiet sleep. Evidence suggests that a diurnal (day-night) pattern exists during the fetal period. Sleep is required for somatic and brain growth and development. Sleep-wake patterns change with central nervous system maturation. In one research study the median relative percentage of time spent in a quiet state was 26%. The median duration of time spent in a quiet state was 15.7 minutes within a 1-hour recording. Both quiet states and active states were established in 84% of the fetuses studied (Piontelli et al., 2015). Infant development entails increasing amounts of quiet sleep as well as increasing periods of quiet alertness. Both states require remarkable neural organization; thus sleep-wake patterns are an excellent window to the infant's neurological status.

Pregnant Woman

Fatigue reflects the significant physical and emotional changes occurring in the pregnant woman. The nurse counsels a woman that fatigue usually subsides by the fourth month but may return later in pregnancy. Rest breaks during the day and 8 hours of sleep each night help prevent fatigue and increase the pregnant woman's comfort. The nurse encourages each pregnant woman to rest when her body signals it is tired because of the rapidly growing fetus and the woman's needs for physical renewal. This encouragement must be directed particularly toward working women, who may need a physician's note for their employer that validates the need for rest during the workday.

Women experience significant sleep disruption and inadequate sleep throughout pregnancy. Many pregnant women do not sleep well because they need to urinate several times a night during the first and third trimesters. In addition, some women experience positional discomfort in late pregnancy that prevents effective sleep and,

therefore, increases their fatigue. Fatigue may influence a woman's evaluation of her role as a pregnant woman, her body changes, and her cultural beliefs related to her ability to succeed in pregnancy. The nurse helps the woman express her thoughts and feelings and find ways to support better sleep and rest patterns (e.g., sleeping upright in a chair at night for easier breathing).

Cognitive-Perceptual Pattern

Fetus

During the prenatal period, although motor functions lag behind, all fetal sensory systems function or nearly function. These systems include vision, hearing, taste, smell, touch, and proprioceptive and vestibular senses (Blackburn, 2014). The fetus with all senses intact experiences the discomfort of pregnancy and the pain of labor contractions. The visual system matures relatively late in gestation, especially compared with the tactile, olfactory, and auditory systems. Although capable of seeing by 30 weeks of age, the fetus has little opportunity to use this ability in utero because of the absence of light (Blackburn, 2014). After approximately 25 weeks, pregnant women note that their babies respond to a loud, sudden noise. Some pregnant women and their partners offer sensory stimulation to the fetus by singing or rubbing the woman's abdomen. This parental behavior may assist in the bonding process between the parent and the baby. Thus the nurse may wish to include this kind of information in prenatal teaching sessions.

Pregnant Woman

Physical and psychological processes remain closely intertwined as pregnancy progresses. Psychological stresses and normal emotional growth affect the physical status of the pregnancy, interactions of the family members, and the eventual relationship between the mother and the infant. When considering the emotional aspects of pregnancy, the nurse recognizes that the woman's personality, environment, physical state, family, and sociocultural and spiritual background

affect the ways in which she handles the psychological changes (Figure 16-4).

FIGURE 16-4 The pregnant woman enjoys time with her family while pregnant.

Two major categories of psychological influences are normal psychological growth required of parents to emotionally and physically prepare them for parenthood, and internal or external stressors on the pregnant woman that decrease her ability to provide the best environment for the developing fetus. The pregnant woman undergoes many cognitive changes that ultimately result in her psychological readiness for motherhood.

Emotional changes.

Hormonal and other physical changes assist the woman in the psychological work of pregnancy. Progesterone level increases affect the woman's general mood, causing her to be more introverted and passive. These mood changes help her to focus her energy on the growing child and her own growth and development. In addition to hormonal changes, the presence, growth, and movements of the fetus become more a part of the woman's experiential self. According to Rubin (1984), the classic researcher on maternal-infant bonding, the

pregnant woman receives immediate sensations of touch, motion, and weight from the fetus that she can share only partially with others. These support a maternal feeling of separateness and uniqueness that causes the woman to turn inward. She frequently worries that the shift in energy away from the world toward herself and her child may cause her to lose contact, drift away from valued relationships, and lose feelings of competence in her areas of achievement. She spends time analyzing her experiences and their possible influence on her effectiveness as a future parent. She constantly studies the qualities of human relationships and shows increased sensitivity and perceptiveness to many people. To others, the woman may seem overly sensitive and analytical during pregnancy (Stockwell, 2015).

Although a woman's mood varies on the basis of a variety of factors and at different times during the pregnancy, many women experience wide mood swings, emotional lability, irritability, and changes in sexual desire. Physical discomforts, hormonal changes, feelings about altered body image, cultural considerations, work and relationship adjustments, and demanding cognitive maturational processes may also cause these emotional changes.

Rubin's classic work stimulated nurses to look beyond the physiological and pathological aspects of childbearing to the intricate process of becoming a mother, and to identify areas for providing help. Current research identifies two simultaneous processes in the transition to motherhood: engagement and growth and transformation. Engagement is making a commitment and being engrossed in mothering through active involvement in the child's care. At the same time, the woman's engagement leads to the woman's growth and transition as she becomes a mother. The bond between a mother and her newborn is one of strength, power, and potential (Hughes, 2015).

Current descriptions for the stages in the process of establishing a maternal identity in becoming a mother include the following:

- Commitment, attachment, and preparation for the pregnancy
- Acquaintance, learning, and physical restoration during the first 6 weeks after birth

- Moving toward a new normal from 2 weeks to 4 months

Nurses can promote the maternal-newborn bond through encouraging skin-to-skin contact, breastfeeding, eye contact, and newborn massage during the first hour after childbirth.

Stressors influencing development.

The mother's age, fears related to a previous fetal loss, feelings about the pregnancy, life situation and culture, degree of stress, loss of control at times, and unintended pregnancy, the presence of other children, and the influence of loved ones may serve as stressors that influence the ways in which the mother completes the developmental tasks of motherhood. Women with unwanted pregnancies have multiple risk factors and would benefit from targeted interventions (Hall et al., 2015; Mori, 2015). A young pregnant woman facing the additional developmental task of adolescence may have difficulty incorporating the pregnant body or the role of mother into her still undefined self-image. Cognitively, she may still be unable to make plans for the baby or even accept the pregnancy until she feels the baby move. Anticipatory guidance is critical when an adolescent faces overlapping developmental challenges of age and pregnancy.

On the other hand, a pregnant woman older than 35 years may feel more isolated by her situation than does the pregnant woman in her 20s. Frequently established in career and family, the older pregnant woman needs to learn to balance her growth and development in these valued areas with her new sense of self. Fears related to being considered at high risk because of age may increase her anxiety and ambivalence about the pregnancy, even if she was previously infertile. As a first-time mother, she may worry about managing the physical demands of labor and delivery, sleeplessness of motherhood, the chances of having an abnormal child, and the need to juggle conflicting life responsibilities and relationships.

A woman with other children moves through the developmental tasks differently from a woman who is pregnant for the first time. Even with a desired pregnancy, the woman may worry about incorporating the new infant into her relationships and managing the

time needed for a new baby. She may have fears and anxieties about labor and delivery because of a previous negative experience. She may be much more aware of the problems involved with caring for a new infant and may not be excited about another pregnancy experience that demands a redefinition of motherhood or additional childrearing expenses.

Developmental Tasks

Rubin (1967, 1977, 1984) describes four major developmental tasks that a woman seeks to accomplish as she learns to become a mother. These include ensuring safe passage through pregnancy and childbirth, ensuring acceptance of the child by significant people in her family, binding to her unknown child, and learning to give of self. According to Rubin, all four tasks must be confronted simultaneously, but each task assumes greater priority at certain times than do other tasks. Each woman works through these tasks on the basis of her unique style, cultural values, and life priorities. At the end of pregnancy, however, all tasks must be integrated to create a presentation, similar to a tapestry (Rubin, 1984).

Ensuring safe passage

- The woman engages in a variety of prenatal care options appropriate to her culture and life experience. For example, pregnant Cambodian women rely on older same-culture women to give prenatal care and advice and rely little on prenatal classes or visits. Some Hispanic American women, on the basis of their view that pregnancy is a healthy, natural experience, may not seek prenatal care but seek a strong matriarchal support system for a positive outcome.
- The woman becomes more protective of herself and the fetus by avoiding crowds, revolving doors, small spaces, and people believed to place the mother at risk. She tires of being pregnant but fears the effect of delivery on her safety and that of her child (Rubin, 1972, 1984). Although sharing fears and desires with her partner, family, or

health care provider helps, only the safe delivery of a normal child can fully free a pregnant woman from her fears to meet this developmental task (Rubin, 1972, 1977).

Ensuring acceptance of the child

- The woman must believe that her child will be accepted into her family based on her definition of family. According to Rubin (1984), the partner's receptivity to the child is particularly important, and many women fantasize about the sex of their child on the basis of a partner's preference.
- The woman frequently judges her partner's degree of receptivity to the infant by the amount of love and attention that she, herself, receives from him during her pregnancy.
- She may desire support from other women, rather than her partner, on the basis of her life experience, values, and cultural background.

Binding into her unknown child

- This task is the most complex cognitive process for the pregnant woman (Rubin, 1984). To accomplish this task, the woman must integrate the fetus as an integral part of herself but also as a separate being. Completion of this task occurs with birth of the baby.
- Initially, the woman fantasizes about the baby through associative images: when she eats an egg, she thinks of the baby. Fantasies in the second and third trimesters relate more specifically to what the child will be like; the woman may imagine the baby in little girl or little boy clothes.
- During the eighth month the woman begins nesting activity by preparing the nursery and thinking increasingly of the baby as an external reality in her home.

Learning to give of herself

- Although the actual mothering activity occurs after birth, the learning process to become a mother begins during pregnancy.
- The woman begins the task by examining what she will gain and

lose by becoming a mother.

- She then explores the meaning of giving by examining how others give to her and to others and how she has given to others in the past (Rubin, 1984).
- Gifts for herself and the baby represent meaningful manifestations of her own and others' acceptance of her motherhood and her ability to give to her child and develop her identity as a mother (Rubin, 1967, 1972).

Self-Perception–Self-Concept Pattern

To develop a maternal identity, the woman must first accept the pregnant body image. Initially she may show ambivalence based on her need to "fit" the pregnancy with her perception of self. She may dislike the physical changes of pregnancy or gladly "show off" her pregnant body to others. During the second trimester, however, the woman frequently begins to feel more positive about her changing womanly image as she feels the baby move, and increased amounts of estrogen and progesterone enhance her sense of vitality, inner peace, and acceptance. Her body begins to look pregnant, and generally others respond positively to this change (Rubin, 1972).

By the third trimester, however, the woman frequently tires of the pregnancy. Her sense of awkward moments supersedes feelings of well-being. She may experience uncomfortable, sleepless nights, the constant need to urinate, Braxton Hicks contractions, and other discomforts. Some women experience infant movement or mild contractions as pleasurable, sensual sensations, whereas others find them extremely uncomfortable. By pregnancy's end, these women yearn to have their former body boundaries back, to hold the baby in their arms, or to have someone else carry the baby.

After birth the woman gradually sees the infant more and more as a separate individual, dependent on her care. The mother starts to bond with her baby on the basis of her self-perception. If she feels good about herself, she will show love toward the infant; when she feels ugly or unlovable, she may make uncomplimentary remarks about the

infant's appearance (Rubin, 1984).

Maternal Role

The pregnant woman's personality, maturity level, and psychological development influence her readiness to assume the role of a mother. The way in which society in general and her culture in particular perceive motherhood and the role of women, as well as the way in which her own views mesh with these perceptions, will affect the ease of the transition. The family situation, the availability of peer role models, and the relationship with her mother are also significant. Internalization of the mother role occurs only after the birth, when the woman interacts with the infant in a reciprocal relationship (Rubin, 1977).

Nursing Interventions

The woman may feel overwhelmed by her feelings and thoughts during pregnancy. Although others acknowledge her physical changes, only she experiences the psychological changes of excitement, ambivalence, or confusion associated with being pregnant.

During prenatal assessment, the nurse should address expected cognitive changes and self-image issues with each pregnant woman and respond nonjudgmentally to concerns expressed in this area. In one-to-one sessions or group prenatal classes, women and their partners should be encouraged to discuss their ideas and feelings related to the emotional and relationship changes expected during pregnancy, because these changes influence the future intimate relationship.

Education on and practice of the maternal role and being a mother is an effective intervention in increasing self-confidence in caring and maternal identity. During their transition to motherhood, pregnant women want attentive, proactive, professional psychosocial support from nurses. They expect nurses to oversee the transition period and to be capable of supporting them in dealing with changes in

pregnancy and in preparing them for birth and motherhood.

Roles-Relationships Pattern

The pregnant family changes throughout the pregnancy and postpartum period as each family member explores and responds to new roles and relationships. A pregnant woman without a partner may feel isolated during pregnancy and depend on family or friends as she adjusts to her situation. Cultural beliefs and traditions may produce stresses during pregnancy, change roles and relationships, or provide emotional and physical support to the pregnant family as it prepares for the baby.

The partner of the pregnant woman faces many new situations that influence that person's parental development. The pregnant woman may seem to be a different person to others because of her emotional response to the pregnancy, introspection, fantasies, need for more rest, and changes in sexual drive. The partner may feel a rivalry with the fetus and baby because the mother is devoting increasing amounts of time to the baby. He may resent the attention that she receives during the pregnancy and the additional demands that she may make on his time. He may experience more financial pressure because of baby expenses and his partner's need to stop working on a short-term or long-term basis. These perceptions may lead him to batter or otherwise abuse his partner, possibly causing poor pregnancy and newborn outcomes (Box 16-7: Quality and Safety Scenario). The nurse assesses each pregnant woman for abuse and intervenes appropriately to protect the safety and health of the family during gestation.

Box 16-7

Quality and Safety Scenario

Birth Outcomes in Abused Pregnant Women

Nurses and other providers who deliver health care to women must address the issue of abuse of the pregnant woman by an intimate

partner. Intimate partner violence is a significant public health problem with negative physical and psychological outcomes. It has been associated with increased levels of STIs, preterm labor, low-birth-weight infants, anxiety, substance abuse behaviors, and postpartum depression (Alhusen et al., 2015). Consider the following research study and the questions that follow to understand the issue further.

Several studies have attempted to identify risk factors associated with experiencing violence during pregnancy. However, all these studies compared women who were abused during pregnancy with nonabused pregnant women. To further the understanding of risk factors for experiencing violence during pregnancy, it may be useful to investigate factors that differentiate female victims of intimate partner violence who were and were not victimized during pregnancy. This will allow us to shed light on unique aspects of pregnancy violence. In addition, the current study examines risk factors using a nationally representative sample. The **risk factors** identified included young age, less than a high school education, unemployment of mother and/or father, dissatisfaction with relationships alcohol problems, and violence in the family of origin; unmarried status increased the risk of violence during pregnancy, but the relative risk was even greater if the women separated or divorced while pregnant; paternal uncertainty and accusations of infidelity have been associated with an increased risk of violence among pregnant women (Slep et al., 2015) . Male partners may develop paternal assurance tactics, such as the use of violence to establish control, to combat paternal uncertainty, and to increase the probability that the children they raise are their own and there is no infidelity on the part of the woman. Patriarchal domination has also been linked to an increased risk of violence against women. Pregnancy may symbolize a time when the woman assumes more control over her own body and may represent a degree of independence from her male partner; violence against the pregnant partner may represent a male partner's attempt to reassert control. Many women who are abused during pregnancy have reported that

their partners attempt to socially isolate them from family, friends, and other social support systems. Most women reporting physical violence during pregnancy are also victims of verbal abuse and psychological aggression. Psychological abuse may be the predominant form of abuse during pregnancy in some cultures. Women who had a partner with a drinking problem were more than three times as likely to be abused during pregnancy compared with women whose partner did not have a drinking problem.

The **health outcomes** of violence against pregnant women include being kicked, punched, thrown down stairs, threatened with knives, choked, scalded, pushed out of moving cars, and having objects thrown at them. A number of violence-related injuries also include cuts, bruises, fractures, concussions, dental injuries, stab wounds, vaginal bleeding, and persistent headaches. Mental health issues include depression, stress, distress, fearfulness, anxiousness, and feelings of isolation.

Nursing Implications

Overall, this study indicates a need for nurses to screen women for high-risk factors prenatally, to be aware of the health risks secondary to violence, and to tailor nursing interventions supportive of pregnant women facing abuse. Nurses need to be aware of the issues surrounding pregnancy violence and have the ability to provide pregnant women with the resources and information necessary to ensure their safety.

Questions

- How do the current health care system and the sociopolitical context of care in the United States contribute to the high numbers of pregnant women facing abuse from their intimate partners?
- What kind of interventions do you believe would be effective for these abused women?
- How should US health care policy ethically and legislatively

address the problem of intimate partner abuse during pregnancy?

From Alhusen, J. L., Ray, E., Sharps, P., & Bullock, L. (2015). Intimate partner violence during pregnancy: Maternal and neonatal outcomes. *Journal of Women's Health*, *24*(1), 100–106; Brownridge, D. A., Taillieu, T. L., Tyler, K. A., Tiwari, A., Ko Ling, C., & Santos, S. C. (2011). Pregnancy and intimate partner violence: Risk factors, severity, and health effects. *Violence Against Women, 17*(7), 858–881; Slep, A. M. S., Foran, H. M., Heyman, R. E., Snarr, J. D., & USAF Family Advocacy Research Program. (2015). Identifying unique and shared risk factors for physical intimate partner violence and clinically-significant physical intimate partner violence. *Aggressive Behavior, 41*, 227–241.

The male partner may be concerned about his ability to fulfill the father role and support his wife or significant other. His fathering role models may be limited because of a lack of contact with his own father or because he spends time with men who are not actively parenting. He may never have held a baby before and may worry that he might drop or harm his own child. If his partner experiences pregnancy complications, he may feel guilty about causing the pregnancy. Table 16-5 gives a more complete list of both the father's and the mother's emotional responses to a first pregnancy. The nurse must work with the pregnant family to help the family adapt to a first pregnancy, because this one affects how the family will cope with subsequent pregnancies.

TABLE 16-5

Possible Responses to First Pregnancy

Phase of Pregnancy	Father's Response	Mother's Response
First trimester	Fear of losing wife or child	Loss of interest in coitus
	Self-doubt as a future father	Possible less sexual effectiveness
	May develop new hobby outside of partner as way of distancing self	Sleepiness and chronic fatigue
		Nausea
		Increased dependence Feels ambivalent toward reality of pregnancy Anxious about process of labor and prospect of caring for a child Worries about miscarriage Becomes aware of physical changes in her body May develop a closer relationship with her mother with a common experience of motherhood
Second trimester	Increased respect	Solemnity, hilarity, and playfulness about fetal movements

	Awe as quickening comes	Talks about and with fetus
	Names for fetus coined	Increased eroticism
	May give partner extra attention she desires	Expects partner to demonstrate interest in caring for her and baby
	Feeling of change, accepting the reality of the pregnancy	Feels movement and thinks of child as an individual
Third trimester	Fear of coitus hurting fetus	Abstinence (often recommended by physician)
	Abstinence difficult	Sleepiness
	Envy or pride, or both, at wife's creativity	Backache
	Concern about identity as a "father"	Abdominal discomfort
	Worry about birth	Sexual isolation
	Keen awareness of male-female differences	Heightened sense of femininity
	May show a greater level of tenderness and protectiveness	Assembles items needed for care of infant and selects possible names
Postpartum period	Eagerness to resume marital relations	Pain and fear of harm from too early coitus
	Concern over endangering wife's recovery	Low eroticism
	Sense of triumph in becoming a father	Concern about effect on husband of continued abstinence
	Tenderness toward wife and baby	Sense of completion as a mother
Pregnancy as a whole	Increased romanticism	Increased romanticism
	Increased nurturance	Increased optimism
	Increased family life participation	Family roles replacing marital emphases
	Financial stress	Fear of miscarriage or problems with baby
	Concern about lack of skills in baby care	Pride of accomplishment
		Emotional stress, feeling overloaded

From Golian Tehrani, S., Bazzazian, S., & Dehghan Nayeri, N. (2015). Pregnancy experiences of first-time fathers: A qualitative study. *Iranian Red Crescent Medical Journal*, *17*(2), 12271–12273; Nierenberg, C. (2015). Mood swings & mommy brain: The emotional challenges of pregnancy. *Live Science.* http://www.livescience.com/51043-pregnancy-emotions.html; Rigby, F. B. (2015). Common pregnancy complaints and questions. *Medscape.* http://emedicine.medscape.com/article/259724-overview.

Children in the family also experience role changes during and after the pregnancy. The very young child, unaware of the concept of a new baby before the infant arrives, may experience a changed relationship with his pregnant mother. She may have less time to play, be more irritable from fatigue, or limit or stop active play late in pregnancy because of increased awkwardness and concern about her safety. After the baby has arrived, the child may be kept away from both the baby and the mother by well-meaning friends and relatives, have to share parents with others, or may want to breastfeed from the mother as the baby does. When permitted to see the newborn, the child may be admonished to "be careful" or "don't touch the baby." Thus a

young child may not accept the baby with open arms.

The older child understands the newborn's significance more clearly but still experiences apprehensions about the effects of the baby on the family. Older children may have been told that they will become a big brother or sister, but does this mean they will lose toys and time with their parents and have to give up a private bedroom? Older children may worry about their mother, who seems more tired, less available, and perhaps even sick at times. Her enlarging abdomen may appear frightening. With help from the nurse, parents can make pregnancy an exciting time of learning and growing for the family (Box 16-8). Chapter 18 discusses the sibling relationship in greater detail.

Box 16-8

Nursing Strategies to Help Parents Prepare Siblings for the Neonate

- Explain the pregnancy and birth appropriate to the child's age.
- Answer all the child's questions.
- Use relevant literature to educate the child about the coming baby.
- Encourage discussion and questions by talking about the new baby during relaxed family times rather than during busy, rushed times.
- Have the child participate in decisions, such as choosing a name, clothes, and toys for baby.
- When sibling classes are available as part of the childbirth education process, encourage parents and the child to attend.
- Suggest that the child go with the mother during clinic or office visits.
- Allow and discuss negative comments about the pregnancy or baby.

- Encourage the child to make drawings or give small gifts to the baby when it is born.

In extended families, expectant grandparents also experience changes during the pregnancy of their daughter or daughter-in-law. The maternal grandmother, seeing her daughter assume the mother role, may now view her daughter as a rival because they are both mothers. The grandparents may be reminded of their own aging, resenting when their advice about pregnancy and parenting goes unheeded. A positive outcome of a pregnancy may be a new closeness between the woman and her mother if the woman turns to her mother to seek advice and share feelings. The nurse may encourage expectant parents to use pregnancy as a transition time for their own parents, which can enhance extended family cohesion in the future.

During pregnancy and after birth, each family member begins to establish an emotional attachment to the imagined or real new baby. Research shows that when the mother has a strong support system to develop deep feelings of attachment to the fetus, she will most likely attach to the baby after birth. Therefore the nurse assesses the support system of each pregnant woman and implements primary and secondary interventions to increase family bonding with a new baby.

Sexuality-Reproductive Pattern

The pregnant woman's body image and merging of this body image with her definition of femininity greatly influence her feelings about her sexuality. For a previously infertile couple, achieving pregnancy may be a blessed event, despite the need for technology that affects a woman's concept of self and femininity and a man's concept of self and masculinity. The reflections of others, particularly those of a pregnant woman's husband, partner, or friend, help a woman to accept changes in her body, leading to better adjustment in their sexual relations.

On the other hand, women may experience different sexual feelings during pregnancy. Some women experience an increase in desire, but many worry about intercourse during pregnancy, fearing that it will

cause **miscarriage**, infection, or an early birth. Other women may experience nausea during pregnancy or simply lack sexual interest. Physical discomfort, fatigue, and awkwardness as well as fear of membrane rupture, infection, or harm to the fetus may also diminish the woman's interest in sexual relations. Sexual dissatisfaction of the couple may result from restrictions in sexual positions, pain on penetration, increased vaginal discharge, breast tenderness, or the other physical discomforts of pregnancy such as fatigue and heartburn. In some cases, the enlarging uterus will require the couple to modify the positions for intercourse, particularly during the latter part of pregnancy. The couple's feelings about the woman's changing body may alter their sexual relationship. The nurse's first step in primary prevention intervention in this area is to support the couple's needs and to relate, in a sensitive fashion, accurate information that facilitates couple intimacy during pregnancy.

Some women experience a decreased desire for sexual intercourse but an increased desire for holding, touching, and other signs of physical affection from their husbands or partners. The nurse encourages the couple to explore other activities for mutual sexual satisfaction.

In summary, the nurse can use the following guidelines concerning sexual activity:

- Sex is generally considered safe in pregnancy.
- Abstinence should be recommended only for women who are at risk of preterm labor, multiple gestation, premature rupture of membranes, unexplained vaginal bleeding, or antepartum hemorrhage because of placenta previa.
- There is little evidence to show that sex at term may help induce labor, but this practice is considered safe in women with low-risk pregnancies (Zakšek, 2015).
- The resumption of intercourse postpartum should be dictated by a woman's level of comfort.

Coping–Stress Tolerance Pattern

Physical and psychological adaptations of the woman to pregnancy affect her perception of stressors and her ability to cope with all aspects of her life. Even normal discomforts of pregnancy may be stressful for a woman, mandating her to modify her usual routine to cope more effectively. Anxiety tends to be high during the first trimester as the woman adapts to pregnancy and anticipated life changes. During the second trimester the woman feels less anxious, but anxiety returns during the third trimester with impending labor and delivery. Throughout pregnancy women may demonstrate their anxieties through psychosomatic complaints and behaviors, such as nausea and vomiting after the first trimester, excessive eating, food cravings, sleeplessness, and fainting. Realistically, every pregnant woman probably experiences some degree of stress. However, many women have considerable stress or ongoing stress, such as poverty, marital difficulties, or unsatisfactory living or working conditions, that influences their coping abilities.

A pregnant woman's anxieties may be reflected in her dreams and fantasies. Many pregnant women report dreams about their babies being deformed or dead, themselves dying, or a family member being injured. Many women at the end of their pregnancies express fears about body mutilation with delivery. Other women may manifest their anxiety by smoking, drinking, or using drugs (legal or illegal), all of which can harm the fetus. Prenatal depression and/or anxiety has been associated with excessive activity and growth delays in the fetus, as well as prematurity, low birth weight, disorganized sleep, and less responsiveness to stimulation in the neonate. Infants of depressed/anxious mothers have difficult temperaments, and later in development attentional, emotional, and behavioral problems have been noted during childhood and adolescence, as well as chronic illnesses in adulthood. Caring for a newborn requires energy, patience, and emotional presence, which are all lacking in a depressed mother (Rode & Kiel, 2016). The nurse must direct a pregnant woman who is not coping well to relevant resources for assistance. The nurse must also assess each woman's progress in taking on the mothering role as the pregnancy nears term. This information can be shared with

the postpartum nursing staff to encourage discussion in this important area.

The nurse encourages the pregnant woman to use tension-relieving strategies such as listening to soft music, using humor, crying, sleeping, talking to a friend, meditating, exercising, and fantasizing during times of stress. These strategies are safe for the fetus and provide relief from many normal tensions and anxieties during pregnancy and afterward. Overall, the nurse plays a key role by responding nonjudgmentally and promoting the coping of women during pregnancy.

Values-Beliefs Pattern

Although pregnancy has been described as the fulfillment of the deepest and most powerful wish of a woman, this fulfillment often coincides with a woman's fear of losing part of herself. She gives up some relationships and pleasures to assume other anticipated satisfactions. She may find that she values friendships with other mothers now, whereas before pregnancy her friendships focused on work or school colleagues. She may discover much to her husband's confusion that she values different qualities in him than she did before anticipating birth. Her husband may also experience a shift in his values.

Pregnant women and their partners may experience changes in their spiritual values. For women with strong spiritual needs related to their cultural backgrounds, spiritual interventions will help them integrate various dimensions of their lives, develop the ability to parent successfully, and find meaning in the changes and goals of pregnancy. Seen as a mystical event or miracle, conception may lead to an increased faith in God or a favorite saint. Nonreligious couples may start to attend church after the baby's birth because they want religion to be part of their child's life. Religious beliefs may influence a woman's decision to undergo certain tests or procedures, such as amniocentesis or abortion. Some women may feel forced to reproduce because their religious or cultural mores forbid contraception or encourage large families. In these groups, each pregnancy may be

seen as another unwanted, but unavoidable, burden or may be valued because having more children signifies a stronger family.

Environmental Processes

Physical Agents

A healthy infant is the outcome of most pregnancies. However, genetic abnormalities and environmental hazards may cause fetal harm, spontaneous abortion (natural loss of conceptive products), or minor or serious congenital defects. Diagnostic methods that identify an early pregnancy or a fetal loss may assist couples in practicing healthy decisions to prevent loss or congenital abnormalities. The WHO (2015) estimates that congenital defects affect 3% to 4% of all live births and contribute to infant mortality rates by causing structural or functional disability incompatible with life. Every year an estimated 276,000 infants worldwide die of congenital anomalies within 1 month after their birth. Real-time ultrasonography identifies approximately 85% of fetal anomalies by 36 weeks of gestation. The best time for a fetal scan is at 18 to 20 weeks of gestation (Rayburn et al., 2015). This knowledge, gained before giving birth, permits expectant couples and the health care delivery team to access resources for improving the baby's life or to support a grieving family if the baby is not expected to live. With progress made in diagnostic tools and the Human Genome Project, some couples may be able to prevent fetal defects or manage them during pregnancy to improve the quality of their baby's life after birth (see the case study at the end of this chapter). Unfortunately, even when no genetic or congenital defects exist, the fetus may still be injured during the process of labor and delivery and face a lesser quality of life.

Teratogens are environmental agents that cause spontaneous abortions or congenital defects. Unlike genetic abnormalities, which occur only at conception, environmental agents may affect the developing infant at any point during gestation. Fetal organs have critical periods of development, and if affected at that time by a teratogen, the infant may have a defect in that organ system. Teratogens normally do not cause a congenital defect during the first 14 days after conception. However, the embryo may be lost later

during early gestation (a spontaneous abortion). Therefore as a primary prevention strategy, any woman contemplating or attempting pregnancy should be counseled to avoid teratogens that might cause fetal loss or damage.

Physical Factors and Diagnostic Tools

Modern diagnostic tools, such as ultrasonography, amniocentesis, chorionic villus sampling, and alpha-fetoprotein screening have been used to identify a number of fetal problems. Certain risk factors, some of which may be found in the family history, or maternal and paternal age, maternal illness, or previous fetal abnormalities, may indicate the need for these diagnostic tools during a woman's pregnancy. These tools commonly identify problems related to abnormal size or rate of fetal growth, chromosomal abnormalities, NTDs, and fetal lung immaturity. The nurse, in consultation with the health care team, must participate in providing informed consent to women before these diagnostic tools are used.

Biological Agents

Biological processes in the fetal environment, which include infections and other health problems of the mother, may affect fetal growth and development. A pregnant woman who acquires an asymptomatic viral infection may not seek health care because she believes that the fetus will not be harmed. However, viral agents may cause fetal damage early in pregnancy. The woman with a health problem, such as diabetes, may also cause fetal damage if she fails to adhere to her health care provider's directives.

When the nurse discusses with pregnant couples the effects of biological processes on the fetus, she must emphasize that the timing of the maternal infection or illness is critical to predicting fetal defects. Maternal infections during the first trimester of pregnancy may cause severe fetal defects or death, depending on the organism. Infections later in pregnancy may also seriously affect the fetus, but less often. Unfortunately, pregnancy renders many women more susceptible to

viral illness, supporting an argument for all women of childbearing age to be fully immunized. Many vaccines (measles, mumps, rubella, and polio) cannot be given during pregnancy because of potential risk to the fetus, but others present no risk (tetanus and diphtheria). A TORCH (*t*oxoplasmosis, *o*ther agents, *r*ubella, *c*ytomegalovirus, *h*erpes simplex; other infections include *Treponema pallidum*, hepatitis viruses, HIV, varicella, parvovirus B19, and enteroviruses) screen may be done to detect the presence of teratogenic perinatal infections: toxoplasmosis, hepatitis B, rubella, cytomegalovirus infection, and herpes simplex (Table 16-6). TORCH infections are major contributors to prenatal, perinatal, and postnatal morbidity and death. Evidence of infection may be seen at birth, in infancy, or years later. For many of these pathogens, treatment or prevention strategies are available, but early recognition, including prenatal screening, is essential.

TABLE 16-6

TORCH Perinatal Infections

Infection	Agent	Source	Fetal-Neonatal Risks	Comments
Toxoplasmosis	Protozoan *Toxoplasma gondii*	Raw or undercooked meat; unpasteurized goat's milk; feces of infected cats	Fetal growth restriction, hydrocephaly, seizures, neurological and cognitive effects, chorioretinitis, intracranial calcifications	Instruct mother to not eat undercooked or raw meat; avoid exposure to cat litter
Other/hepatitis B	Hepadnavirus	Blood or blood products; sexually transmitted via body fluids	Generally asymptomatic, but majority become chronically infected	Newborn should receive HBIG within 12 h after birth and hepatitis B vaccine postpartum
Rubella	Rubella virus	Direct or indirect contact with droplets of infected person	CNS defects, developmental delay, deafness, cataracts, IUGR, microcephaly, cardiac defects, glaucoma	Screen all pregnant women with rubella antibody titers
Cytomegalovirus	Herpes virus	Transmitted by droplet infection from person to person	Microcephaly, fetal growth restriction, CNS abnormalities, deafness, blindness, jaundice, gastrointestinal defects, seizures	Prevention of maternal primary infection in early pregnancy; stress good personal hygiene
Herpes simplex	HSV-1 and HSV-2	Sexually transmitted infection to mother; fetus contacts it during birth from genital lesions	Intense herpetic lesions on eyes, mouth, and skin; keratitis; conjunctivitis	Practice safer sex; careful handwashing; surgical birth if active lesions

CNS, Central nervous system; *HBIG,* hepatitis B immune globulin; *HSV-1,* herpes simplex virus type 1; *HSV-2,* herpes simplex virus type 2; *IUGR,* intrauterine growth restriction.

Toxoplasmosis

Toxoplasmosis is caused by a protozoan that infects people through consumption of undercooked meat, handling of feces of cats that become infected by eating infected rodents and birds, and exposure to contaminated soil, in countries outside the United States (CDC, 2015c). An infected pregnant woman is usually asymptomatic but may have flulike symptoms or mild to severe upper respiratory tract symptoms believed to be unrelated to an infection. Vertical transmission from an infected pregnant woman to the fetus predominantly occurs when infection is acquired for the first time during pregnancy. Overall, approximately one-third of infected pregnant women give birth to an infant with toxoplasmosis, and the risk of vertical transmission rises sharply with gestational age at maternal infection. However, fetuses infected during an early pregnancy period are much more likely to show clinical signs of infection, such as chorioretinitis, hydrocephalus, or intracranial calcification (King et al., 2015). Approximately 60% of maternal infections acquired during the third trimester will result in fetal infection, which might manifest itself as rashes, enlarged lymph nodes and liver, inflammation of the heart, pneumonia, jaundice, or severe central nervous system damage after birth or years later (CDC, 2015c). Nurses can offer some simple hygiene suggestions that reduce the risk of infection. For example, humans can acquire toxoplasmosis from eating undercooked or raw meat (especially lamb and pork), from being exposed to contaminated soil or water, or from consuming uncooked vegetables. Clearly, nurses should advise pregnant women to cook meat thoroughly and wash and scrub vegetables well,

especially those eaten raw. Pregnant women should use good handwashing hygiene, avoid eating raw meat, wear gloves when gardening, and avoid handling cats or cleaning cat litter boxes to avoid exposure to *Toxoplasma*.

Syphilis

Syphilis is an STI that can be transmitted through oral, anal, or vaginal contact. An infected mother transfers **syphilis**, caused by a bacterium, to her fetus. The causative organism, *Treponema pallidum,* can be transferred across the placenta and can infect the developing fetus as early as at 9 weeks of gestation. The risk of vertical transmission and infection in the newborn is directly related to the stage of maternal syphilis during pregnancy; transmission occurs more frequently during primary or secondary syphilis in the mother than during latent stages of the disease. Although syphilis is preventable and treatable, the number of congenital and neonatal syphilis cases has increased in the last several years (CDC, 2015d). Maternal risk factors for acquiring syphilis include homelessness, **human immunodeficiency virus (HIV)** positive status, single marital status, and a history of STIs. Maternal syphilis has been associated with complications such as **polyhydramnios**, spontaneous abortion, and preterm births. Fetal complications such as fetal syphilis, fetal hydrops, prematurity, fetal distress, and **stillbirth** also occur. Neonatal complications can include congenital syphilis, seizures, neonatal death, and late sequelae (Singh & McCloskey, 2015). The infant may be born with localized mucocutaneous lesions, nasal congestion, anemia, and generalized septicemia, but may appear healthy at birth only to have symptoms appear later. Routine testing of high-risk women for syphilis at the first prenatal visit and during the third trimester and antibiotic treatment (benzathine penicillin G) for affected women and their partners have reduced the number of infants with congenital syphilis (King & Brucker, 2016).

Rubella

Despite the broad use of the measles, mumps, and rubella vaccine, or MMR, and the resulting immunity to rubella, approximately 20% of women reach their childbearing period without immunity to this disease (USDHHS, 2010). The risk of vertical transmission from a nonimmune mother with primary rubella infection in the first trimester of pregnancy is considerably high at 80% to 90%. Beyond the first 12 weeks of gestation, fetal organogenesis is nearly complete, and deafness may be the only consequence in the infected infant. Deafness, cataracts, and cardiac defects are the classic congenital anomalies associated with a rubella infection (Silasi et al., 2015). The symptoms of rubella may cause the mother to think she has a minor viral infection, but rubella during the first trimester may cause improper fetal development of the ears, eyes, and heart and deafness. No treatment exists for an infected fetus; however, a pregnant woman may receive the vaccine to protect future pregnancies if she has no history of rubella infection. After giving birth, new mothers often receive the vaccine before being discharged with a recommendation to avoid pregnancy for at least 3 months to prevent fetal harm from the vaccine.

Cytomegalovirus

Cytomegalovirus (CMV) is a virus in the herpes virus family and is a leading cause of congenital infections and long-term neurodevelopmental disabilities among children. Contacts with young children have been identified as the main source of virus transmission to mothers. It is the most common infection that can cause serious fetal complications. CMV infects an estimated 1% to 2% of all infants born in the United States. Most mothers infected with CMV have mild, often nonspecific symptoms, but their infants may experience hearing loss, blindness, enlarged liver and spleen, seizures, intracranial calcifications, and neurodevelopmental disabilities (Kovacs & Briggs, 2015). Unfortunately, no means exist to prevent or manage this viral infection. Perhaps an immunization similar to that for rubella will be developed in the future. Until vaccines and nontoxic antiviral agents are available, hygienic measures are

important as prophylaxis and should be emphasized by all nurses to their prenatal clients.

Herpes Simplex Virus

Herpes simplex virus infections remain extremely common today, with many people unaware that they have the disease. It is estimated that 16% of adults in the United Sates are infected with herpes simplex virus. Herpes is lifelong infection that has the potential for transmission throughout the life span (King et al., 2015). Herpes simplex may cause spontaneous abortion or fetal neurological damage. Infants infected at birth may show localized or generalized disease with symptoms of vesicular skin lesions, microcephaly, hydrocephalus, chorioretinitis, conjunctivitis, seizures, respiratory distress, or gastrointestinal bleeding. These symptoms may cause newborn death. An infant delivered vaginally by a woman with active genital herpes has a 40% to 60% chance of being infected (CDC, 2015e), supporting a decision for a cesarean delivery for any women with active vaginal or perineal herpes lesions. Risk factors for the transmission of herpes from the mother to the newborn have been detailed. The pregnant woman who acquires genital herpes as a primary infection in the latter half of pregnancy, rather than before pregnancy, is at greatest risk of transmitting this virus to her newborn. This is true for both herpes simplex virus type 1 and herpes simplex virus type 2 (Kovacs & Briggs, 2015). Generally, an antiviral agent is recommended during pregnancy for treatment of viral lesions. The nurse educates the infected woman about comfort measures at this time, including ways to keep the lesions dry and application of comfort measures to reduce the pain of the lesions (Queenan et al., 2015).

Zika Virus Disease

Zika virus is transmitted to humans primarily through the bite of an infected *Aedes* species mosquito during the daytime. The most common symptoms of Zika virus disease are fever, rash, headaches,

bone pains, joint tenderness, and conjunctivitis. The illness is typically mild, with symptoms lasting for several days to a week after the person has being bitten. Up to 80% of people infected with the virus have no symptoms (CDC, 2016). The virus is in the Caribbean, as well as parts of Central America and South America. The virus has been reported to be spread through blood transfusions and sexual contact and can also be passed from a pregnant woman to her fetus, and has been linked to a serious birth defect of the brain termed microcephaly. The CDC, WHO, and other scientific organizations are working to understand this possible link.

In 2016 the World Health Organization (2016) declared Zika virus a public health emergency of international concern. The CDC recommends abstaining from oral, anal, or vaginal sexual contact with anyone who has traveled to areas with active infections. Pregnant women are also discouraged from traveling to regions with active infections (CDC, 2016). At this time there is no vaccine given to prevent Zika virus disease or antiviral medication to treat the infection. Prevention measures would include better housing construction, use of insect repellents, wearing long-sleeved shirts and pants, regular use of air conditioning, use of window screens, avoidance of traveling to mosquito-infested areas, and state and local mosquito control efforts.

Chlamydia, Gonococcus, Group B Streptococcus, Bacterial Vaginosis, and *Candida albicans*

Infections caused by chlamydia, gonococcus, group B streptococcus, and yeast ***(Candida albicans)*** may occur in the woman's vagina or cervix, infecting the infant during a vaginal birth. **Chlamydia**, the most common bacterial STI, appears most often among poor women with little access to care. Although few symptoms are seen, infection may cause preterm labor, premature rupture of membranes, low-birth-weight infants, or newborn conjunctivitis or pneumonia. Routine treatment of the newborn's eyes after birth with erythromycin or other effective antibiotic ointment destroys the organisms. Maternal

gonococcus (GC) infection can be transmitted to the newborn from the mother's genital tract at the time of birth and can cause ophthalmia neonatorum, a systemic neonatal infection, maternal endometritis, or pelvic infection. The risk of transmission from an infected mother to her infant is nearly 50% (Hotchin, 2015). Newborn infants often receive an antibiotic ointment in the eyes to prevent GC infection. Screening at 36 to 37 weeks of pregnancy for **group B streptococcus** infection has been recommended because this infection causes preterm rupture of the amniotic membranes, preterm labor, fetal respiratory distress syndrome, fetal septicemia, and meningitis (Michihata et al., 2015). **Bacterial vaginosis** may also cause preterm labor (Sangkomkamhang et al., 2015). *Candida albicans,* the cause of a common vaginal fungal infection, may also cause an oral infection called thrush in the newborn. Routine assessment of pregnant women, and occasionally their sexual partners (GC), for these bacterial and yeast infections must occur during pregnancy so that treatment can occur and prevent fetal infection at the time of birth.

Human Immunodeficiency Virus

Acquired immunodeficiency syndrome.

The US Public Health Service and the US Preventive Services Task Force recommend that all pregnant women in the United States be tested for HIV infection, ideally at the first prenatal visit (Ross et al., 2015). Any woman in a high-risk group (e.g., intravenous drug users, women who have bisexual partners or multiple sexual contacts, women with a history of STIs, women who engage in sex for money or drugs, or black or Hispanic women living in poverty) should be tested for antibodies to HIV. For the HIV-positive woman or one who engages in high-risk sexual practices, counseling must occur before conception. Counseling should include both the direct effect of the virus on pregnancy and the effect of pregnancy on HIV disease progression. Although unclear, it appears that HIV infection becomes worse during pregnancy because of a woman's altered immune status. Some early pregnancy discomforts, such as fatigue, anorexia, and

weight loss, may mask the early symptoms of HIV infection and thus postpone a definitive diagnosis.

Infants born to HIV-positive women who have taken antiretroviral medications during their pregnancy, in whom the virus is undetectable, and who have avoided breastfeeding have a less than 1% perinatal transmission rate (CDC, 2015f). Affected infants may not be seropositive for HIV for many months after birth and then later develop the disease. The use of antiretroviral medications throughout pregnancy has improved the prognosis of an HIV-positive woman and has decreased viral transmission to the fetus, although the drug remains expensive and may be inaccessible for women who do not receive prenatal care.

The pregnant woman who has **acquired immunodeficiency syndrome (AIDS)** or who is HIV positive should be carefully monitored by a health care team for opportunistic infections that occur frequently. The nurse can be instrumental in helping this woman coordinate her contacts with care providers, answering her questions, and working as a member of the team to provide optimal care for the woman and her child. Frequently the pregnant woman with AIDS does not seek care because of fears of being reported for her disease. Involving the woman in continuous prenatal care decreases her risk of preterm rupture of membranes, problems with fetal growth, postpartum infection, drug and alcohol abuse, and difficulty in addressing sociocultural barriers to a better life (Adam, 2015).

Although important in decreasing the transmission of any disease, astute preventive measures are mandatory for nurses who are exposed to HIV-infected body fluids, such as blood, amniotic fluid, and vaginal secretions (standard precautions should be followed). All health care providers must follow hospital and birth center policies regarding the use of gloves and gowns and the disposal of needles and other potentially contaminated equipment to prevent the transmission of this disease in particular.

Hepatitis B

Hepatitis B virus (HBV) is a serious global public health problem with more than 2 billion people infected and more than 1 million deaths occurring annually because of cirrhosis and liver carcinoma (Reddy et al., 2015). HBV infection remains a significant concern during pregnancy because it affects the maternal liver and has a high fetal transmission rate (40%) if present during the third trimester. High-risk groups for HBV infection include women from Asia, Pacific Islands, and sub-Saharan Africa, as well as health care workers, intravenous drug users, and women with multiple sexual partners (CDC, 2015g). On the basis of the large number of infected women who fail to show symptoms until liver damage has occurred, all pregnant women early in pregnancy and those at risk should be screened routinely for HBV (Queenan et al., 2015). HBV immunization (three injections over a period of 6 months) may be given before or during pregnancy to a mother who is seronegative (CDC, 2015g). According to Jhaveri (2015), most women harboring HBV transmit it vertically through the placenta to the fetus or through contaminated urine, feces, saliva, or vaginal fluids during birth. Many women carrying HBV deliver prematurely, and some infants may have acute hepatitis or later develop liver cancer.

Other Health Concerns

Pregnant women may also develop any of the infections of nonpregnant women. For example, pregnant women frequently experience upper respiratory tract and gastrointestinal tract infections, adding to the discomforts of pregnancy. However, there is no evidence the viruses causing these infections have a teratogenic effect on the fetus.

Fever frequently occurs with illness. A high temperature for a prolonged time (hyperthermia) in a pregnant woman may harm the fetus, especially during the first trimester. Some literature indicates that fever is associated with miscarriages, low birth weight, stillbirths, and preterm births (Silasi et al., 2015). Whether the fever or an underlying illness causing the fever has created the problem must be determined. Some reports have also correlated prolonged use of a

sauna or hot tub, causing hyperthermia, with birth defects such as microcephaly, anencephaly, and hypotonia (Biswas et al., 2015). Until health care providers understand this issue better, the nurse should advise pregnant women to avoid prolonged sauna or hot tub use and spending time with people who are ill or carrying disease. When a pregnant woman develops a fever, she should be advised to contact her health care provider immediately.

Pregnant woman may have other health problems that influence their physiological processes and thus harm the developing fetus. Black women experience twice the rate of hypertension and diabetes mellitus of white women. These higher rates may account for the three to four times higher maternal mortality rate seen among pregnant black women as compared with white women (CDC, 2015h). Overall, US women are more likely to die during childbirth than women in any other developed country, leading the United States to be ranked 33rd among 179 countries on the health and well-being of women and children (Robeznieks, 2016).

Diabetes.

Diabetes mellitus is approaching epidemic proportions worldwide, and the effects and treatment of it are still not well understood by the medical community. Diabetes may exist before pregnancy (preexisting diabetes) or start during pregnancy (gestational diabetes), affecting both the mother and the fetus. Pregnancy increases the need for maternal insulin to balance the woman's blood glucose level. Currently the American College of Obstetricians and Gynecologists recommends that all pregnant women complete a glucose tolerance test at 28 weeks of gestation to identify abnormal blood glucose utilization and the need for additional monitoring. Complications from diabetes during pregnancy include polyhydramnios (excessive amniotic fluid volume), acidosis, increased rate of infection, vascular complications, and increased risk of pregnancy-induced hypertension. Because of an increased incidence of intrauterine death after 36 weeks of gestation attributable to an aging placenta, close monitoring in the last month is essential. Neonatal complications from diabetes include

hypoglycemia, respiratory distress syndrome, hyperbilirubinemia, and hypocalcemia. Infants of mothers with diabetes also have a higher incidence of congenital anomalies, such as a heart lesion or meningocele (Langer, 2015). The diabetic pregnant woman needs close health care team supervision and ongoing health teaching, including diet and exercise management, to control her disease effectively for an optimal pregnancy outcome.

Heart disease and hypertension.

The physiological changes that occur in pregnancy can place extra demands on cardiac function. Cardiac disease complicates approximately 4% of all pregnancies in the United States (Gandhi & Martin, 2015). Heart disease and hypertension are two serious maternal cardiovascular problems during pregnancy. Rheumatic heart disease, a common problem that affects more than 34 million people annually, contributes to congestive heart failure, threatening the lives of both the mother and the fetus. The greatest tragedy of all is that it is eminently preventable (Carapetis, 2015). The fetus may require preterm birth to prevent complications. Chronic hypertension, seen more frequently in first-time mothers older than 35 years, increases the chances of stillbirths, preterm births, preeclampsia, chronic hypertension, and development of **gestational hypertension**, which increase both maternal and infant mortality rates. Mothers with these problems must be monitored closely throughout pregnancy to prevent complications (Raio et al., 2015).

Rh blood group incompatibility.

Rh blood group incompatibility, which is a rare occurrence today because of implementation of anti-D immune globulin prophylaxis given to the mother prenatally and postnatally, sometimes affects fetal development. This problem usually occurs when the mother has Rh-negative red blood cells and the fetus has Rh-positive red blood cells, inherited from a father who has Rh-positive blood. In this disorder, maternal antibodies develop, cross the placental membranes, and destroy the Rh-positive red blood cells of the fetus. Depending on the

severity of the response, the infant may develop various levels of hyperbilirubinemia after birth or may die in utero from the anemia of erythroblastosis fetalis (hemolytic disease of the newborn).

All women should be assessed for blood type, Rh factor, and development of antibody to Rh-positive cells at their first prenatal care visit and again at 24 to 28 weeks of pregnancy unless the father of the baby is Rh negative (Moise, 2015). Rh incompatibility between a mother and a future fetus may be prevented by administration of Rho(D) immune globulin (RhoGAM) to a Rh-negative mother at 28 weeks of gestation and within 72 hours after birth. The immunization prevents the mother's sensitization to fetal Rh-negative cells by inactivating fetal red blood cells in the mother before she can develop an antibody response. The ideal injection time is after the mother's first birth of an Rh-positive infant, miscarriage, or therapeutic abortion. The incompatibility generally does not occur during the first pregnancy, and the immunization prevents problems with later pregnancies.

Chemical Agents

Substance abuse in pregnancy remains a major public health problem. The use and abuse of alcohol and other mind-altering drugs has political, legal, socioeconomic, health, mental health, and familial impact felt widely around the world. Drugs ingested by the mother may be teratogenic to the fetus. The tragic experience with the tranquilizer drug thalidomide, which caused limb deformities during the early 1960s, led to a recommendation that medications should be avoided during pregnancy unless absolutely necessary (Box 16-9: Research for Evidence-Based Practice). The fact remains, however, that during the most critical early weeks of fetal development and growth, when many women do not know they are pregnant, ingested drugs may seriously affect the fetus. Depending on fetal gestational age and drug metabolism, drugs may alter the placenta itself or directly affect development and growth of the fetus. The drugs that most commonly cause congenital defects are prescription medications, over-the-counter (OTC) drugs, street drugs, nicotine (cigarettes),

caffeine, and alcohol.

Box 16-9

Research for Evidence-Based Practice

Substance Use in Pregnancy

Objective: To improve awareness and knowledge of problematic substances (alcohol, tobacco, illicit substances of opioids, amphetamine-type stimulants, cocaine, marijuana, and unprescribed prescription drugs) used in pregnancy and to provide evidence-based recommendations for the management of this challenging clinical issue for all health care providers.

Options: This guideline reviews the use of screening tools, general approach to care, and recommendations for clinical management of problematic substance use in pregnancy.

Outcomes: Evidence-based recommendations for screening and management of problematic substance use during pregnancy and lactation.

Evidence: Medline, PubMed, CINAHL, and the Cochrane Library were searched for articles published from 1950 with use of the following keywords: substance-related disorders, mass screening, pregnancy complications, pregnancy, prenatal care, cocaine, cannabis, methadone, opioid, tobacco, nicotine, solvents, hallucinogens, and amphetamines. The results were initially restricted to systematic reviews and randomized controlled trials/controlled clinical trials. A subsequent search for observational studies was also conducted because there are few randomized controlled trials in this field of study. Articles were restricted to human studies published in English.

Recommendations

- All pregnant women and women of childbearing age should be screened periodically for alcohol, tobacco, and prescription and illicit drug use.
- When testing for substance use is clinically indicated, urine drug screening is the preferred method. Informed consent should be obtained from the woman before maternal drug toxicology testing is ordered.
- The 5As of intervention (ask, advise, assess, assist, and arrange) can be a useful framework for encouraging women to quit substance use.
- Pregnant women may require a medically supported inpatient setting to assist them in their recovery from substance abuse.
- Policies and legal requirements with respect to drug testing of newborns may differ by jurisdiction, and caregivers should be familiar with the regulations in their region.
- Health care providers should use a flexible approach to the care of women who have substance use problems, and they should encourage the use of all available community resources.
- Women should be counseled about the risks of periconception, antepartum, and postpartum drug use.
- Women seeking help should be provided with counseling and substance abuse treatment option referrals.
- Smoking cessation counseling should be considered as a first-line intervention for pregnant smokers. Nicotine replacement therapy and/or pharmacotherapy can be considered if counseling is not successful.
- Methadone maintenance treatment should be a standard of care for opioid-dependent women during pregnancy. Other slow-release

opioid preparations may be considered if methadone is not available.

- Opioid detoxification should be reserved for selected women because of the high risk of relapse to opioids.

- Opiate-dependent women should be informed that neonates exposed to heroin, prescription opioids, methadone, or buprenorphine during pregnancy are monitored closely for symptoms and signs of neonatal withdrawal (neonatal abstinence syndrome).

- The risks and benefits of breastfeeding should be weighed on an individual basis because methadone maintenance therapy is not a contraindication to breastfeeding.

Nursing implications: Using these guidelines, nurses can assist in helping pregnant women improve access to health care, and assistance with appropriate addiction care leads to reduced health care costs and decreased maternal and neonatal morbidity and mortality.

Prescription Medications

Women frequently become pregnant while taking medications for illnesses diagnosed before pregnancy, such as hypertension, or they may receive medication to treat an illness acquired during pregnancy, such as a UTI. Some of the more common drugs that have been studied for fetal effects include antibiotics and anticonvulsants.

Most short-term and usual-dose antibiotics do not cause fetal harm. The tetracyclines are harmful to baby teeth formation because they combine with calcium ions and are deposited in deciduous teeth (causing discoloration) and bones (inhibiting bone growth and

causing deformities) (King & Brucker, 2016). Primary teeth seem most affected, but when the antibiotic is given near the time of delivery, the permanent teeth may also be damaged.

On the basis of our current state of knowledge, the vast majority of antibiotics do not cause serious harm to the unborn child if used properly and at the appropriate doses during pregnancy. The treatment with an antibiotic that is contraindicated does not justify termination of pregnancy. However, ultimately no medicine, including antibiotics, can be described as absolutely safe (Doulatram et al., 2015).

The prevalence of antiepileptic drug use in pregnant women is very low. Although their main indication is for management of epilepsy, antiepileptic drugs are increasingly being used in the treatment of bipolar mood disorders, migraine, and neuropathic pain syndrome, which means their prevalence will increase (Tomson & Klein, 2015). The effects of anticonvulsants on the fetus have been documented thoroughly. Women with seizure disorders have carried infants to term while being treated with hydantoin, barbiturates, and other antiseizure medications. Infants born to mothers taking hydantoin (Dilantin) may have fetal hydantoin syndrome, reflected in microcephaly, retardation, cleft lip and palate, and congenital heart disease. Barbiturates, such as phenobarbital, may cause newborn addiction. Women with seizure disorders should discuss their medication requirements with their physicians before becoming pregnant and have close health care team monitoring throughout pregnancy.

Over-the-Counter Drugs

Pregnant women frequently choose to treat minor illnesses with OTC drugs. Research on acetylsalicylic acid (aspirin) and acetaminophen (Tylenol) indicates that both medications are safe in the recommended dosages. However, aspirin alters platelet function and may cause maternal and newborn bleeding if taken close to delivery. Acetaminophen can be toxic to the liver. Certain ingredients in common cold remedies have been associated with fetal irritability

(King & Brucker, 2016). Ibuprofen has been known to prolong labor on the basis of its antiprostaglandin effect. Any drug may harm a fetus, so all drugs should be avoided during pregnancy unless prescribed by the health care provider.

The nurse includes information on the known and probable effects of medications on the fetus in prenatal teaching of couples. Discussion of herbal treatments is included, because little research exists on their effects and interactions with OTC and prescribed medications. The nurse recognizes that many cultural groups use these nontraditional agents because they believe that they will effectively manage pregnancy-related concerns. The nurse may need to encourage an individual to reconsider the use of herbs when evidence exists that these may harm the fetus or mother.

Drug Abuse

Given the prevalence of drug use and abuse in our society, it is imperative that nurses be able to recognize, manage, and refer as appropriate substance abuse problems for their care recipients. Substance abuse during pregnancy poses a significant risk because all substances consumed by the mother pass freely through the placenta, and thus the fetus as well as the mother experiences substance use, abuse, and addiction. All pregnant women and women of childbearing age should be screened periodically for alcohol, tobacco, and prescription and illicit drug use.

Maternal use of narcotics, tranquilizers, cocaine, amphetamines, marijuana, and other drugs may cause serious health problems to both the mother and the unborn child. These drugs represent an enormous cost to society by causing increased risks of low-birth-weight infants and preterm infants, as well as deficits in child development, if the mother ingests them during pregnancy (National Institute on Drug Abuse [NIDA], 2015).

Narcotics.

Long-term narcotic use during pregnancy is increasing in prevalence. Signs of narcotic withdrawal in the newborn include tremors,

irritability, hyperactivity, vomiting, diarrhea, sweating, poor feeding, and possibly convulsions. No evidence suggests withdrawal in infants whose mothers used cocaine or amphetamines, although there is an increased risk of preterm births, neonatal irritability, placental abruption, premature rupture of membranes, and fetal distress (Kremer & Arora, 2015). Frequent maternal marijuana use during pregnancy may cause fetal immunological problems, but evidence conflicts with an unclear impact. Current research has shown that some infants born to women who used marijuana during their pregnancies display altered responses to visual stimuli, increased tremulousness, and a high-pitched cry, which could indicate problems with neurological development (NIDA, 2015). To avoid these problems, nurses must recognize women who abuse drugs and assist them in seeking appropriate help. This task may be difficult because drug abusers often try to hide their habit, fear being reported to the police, and may be unable to change their lifestyle without extensive intervention.

Drug and substance misuse is a serious public health issue in the United States, especially among women of childbearing age. The problem of drug abuse during pregnancy has affected women in all communities, races, and cultures and of all ages and socioeconomic levels. As a result, many infants are born exposed to illicit substances in utero, are addicted, and develop the complex disorder known as **neonatal abstinence syndrome**. This is a drug withdrawal syndrome that most commonly occurs after an in utero exposure to addictive prescriptive or illicit drugs, such as opioids, which has been increasing in prevalence during the last decade (Tolia et al., 2015). Infants with neonatal abstinence syndrome have prolonged hospital stays, they experience serious medical complications, and their treatment is very costly. Any prenatal substance abuse can have lifelong consequences for the newborn.

For early identification of newborns needing interventions, the nurse should observe newborns with a history of maternal drug abuse for the following: hyperactivity, shrill cry, muscle tension, tremors, seizures, sneezing, yawning, restless sleep, disorganized suck,

vomiting, diarrhea, poor feeding, tachypnea, scratches on face, flushing, and sweating. Supporting care for these infants with neonatal abstinence syndrome includes placing them in a quiet area with dim lights, using a tight swaddling position on the side or back, using calming techniques and rocking, clustering infant-care activities with gentle handling, encouraging nonnutritive sucking, providing small, frequent feedings, and administering pharmacological agents as ordered to control withdrawal symptoms.

Nurses need to possess knowledge in the area of chemical dependency, as many women continue to consume nonprescribed drugs during pregnancy. Additionally, knowledge of how to recognize symptoms of withdrawal in infants during the immediate newborn period can lead to improved outcomes if they are treated appropriately during their withdrawal period. Nurses can also help children learn about the negative effects of consuming alcohol and other illicit drugs, especially during pregnancy. By understanding child development and appropriate strategies for teaching children, nurses can play an important role in the prevention of alcohol and illicit drug use among women during pregnancy.

Alcohol.

Alcohol is the most widely used recreational substance worldwide. Many women in today's society drink alcohol regularly. Research has demonstrated that alcohol is a teratogen, a substance that can cause abnormal development in a growing fetus, as it crosses the placenta readily. Recognition of the effects that even low levels of prenatal alcohol exposure can have on the physical and cognitive development of a child led to the coining of the umbrella term **fetal alcohol spectrum disorder** (FASD). Fetal exposure to alcohol throughout pregnancy may cause **fetal alcohol syndrome** (FAS) or fetal alcohol spectrum disorder (FASD), a collection of symptoms including intrauterine growth restriction, increased risk of facial anomalies, structural brain abnormalities, mental health problems, attention-deficit/hyperactivity disorder, and retardation. It is clinically proven that alcohol consumption during all stages of pregnancy puts the fetus

at risk of being born with lifelong alcohol-related brain damage (Viteri et al., 2015). Recent studies have reported symptoms of fetal alcohol disorder in children whose mothers may have consumed just a couple of drinks a day at certain stages of pregnancy. Another study confirmed that fetal alcohol syndrome is not the only problem connected with drinking during pregnancy: it is also a risk factor for early alcohol abuse and dependence in the child (Straussner & Fewell, 2015). Numerous studies have shown that no safe level of alcohol use exists during pregnancy; therefore alcohol consumption should be avoided during this time and when conception is being attempted. The consequences of prenatal alcohol exposure are often grave, inhibiting both physical and intellectual development, societal acceptance, and adult success. The evidence is clear—alcohol can be more damaging to the developing fetus than heroin, cocaine, or any other drug, producing by far the most serious neurobehavioral effects in the fetus. Prenatal alcohol exposure is the leading preventable cause of intellectual disability in the United States. As many as 1 in 20 infants born today are affected by prenatal exposure to alcohol (Bingham, 2015). Nurses need to stress this finding to make all women aware of avoiding alcohol consumption during their pregnancy. Nurses can help deliver the message that alcohol poses grave risks during pregnancy. Eliminating alcohol consumption during pregnancy is an important measure to take to provide future generations with a healthy start in life and reach their full potential in life.

Nicotine.

In the United States it is estimated that approximately 16% of pregnant women smoke during their pregnancies. Carbon monoxide and nicotine from tobacco smoke may interfere with the oxygen supply to the fetus. Nicotine also readily crosses the placenta, and concentrations in the fetus can be as much as 15% higher than maternal levels. Nicotine concentrates in fetal blood, amniotic fluid, and breast milk. Combined, these factors can have severe consequences for the fetuses and infants of mothers who smoke

(NIDA, 2015). The US Preventive Services Task Force (2015b) recommends that clinicians ask all pregnant women about tobacco use and provide an augmented, pregnancy-tailored counseling framework for engaging women in smoking cessation discussions:

- Ask the woman about tobacco use.
- Advise the woman to quit through clear, personalized messages.
- Assess the woman's willingness to quit.
- Assist the woman to quit.
- Arrange follow-up and support.

Evidence indicates that maternal smoking causes increased rates of spontaneous abortion and ectopic pregnancy, decreased fertility, fetal growth restriction, increased numbers of low-birth-weight or preterm infants, placental abnormalities, vaginal bleeding, congenital anomalies, perinatal death, and premature rupture of the membranes. The best advice for pregnant mothers or women considering pregnancy is to cease all use of tobacco products, decreasing smoking if the woman is a heavy smoker, and avoiding places where smoking occurs. The nurse needs to understand the context of smoking in a woman's life and the complexity of her choice to quit smoking so as to propose solutions to decrease fetal exposure to nicotine (Box 16-10: Research for Evidence-Based Practice).

Box 16-10

Research for Evidence-Based Practice

Nicotine Replacement Therapy in Pregnancy

Maternal tobacco smoking during pregnancy is the most significant preventable cause of poor health outcomes for women and their babies, with morbidity resulting from placental abruption, miscarriage, stillbirth, prematurity, low birth weight, neonatal or sudden infant death, and asthma. Frequently, clinicians use nicotine replacement therapy (NRT) in attempts to help pregnant smokers

stop smoking. However, although NRT is an effective smoking cessation treatment for nonpregnant smokers, its efficacy and safety in pregnancy have not been demonstrated adequately.

The purpose of this study was to determine the efficacy and safety of nicotine replacement therapy with or without behavioral support when used to support smoking cessation in pregnancy.

Design, setting, and participants: In a systematic review of randomized controlled trials in which NRT was used with or without behavioral support to promote smoking cessation, trials providing unequal behavioral support to different trial groups were excluded. Included were randomized controlled trials with designs that permitted independent effects of any type of NRT (e.g., patch, gum) for smoking cessation to be isolated. Five trials were identified that met the criteria, giving a total of 525 enrolled pregnant smokers.

Findings: There is currently some evidence to demonstrate that NRT, used by pregnant women for smoking cessation is either effective or safe for long-term use. Although birth outcomes were generally better among those infants born to women who had used NRT, none of the observed differences reached statistical significance. By ensuring that the only difference between the arms of the included trials was the provision of NRT to all participants, the independent effects of NRT that are of most importance to clinicians were isolated. Clinical guidelines assume that when pregnant women are heavily dependent on nicotine, use of NRT will be less harmful to them and their babies than continued smoking; however, these findings have not produced evidence for this assumption. Additional studies are needed to determine the safety and efficiency of NRT.

Nursing implications: In the absence of sufficient evidence for either the effectiveness or the safety or long-term use of NRT in pregnancy, nurses should perhaps emphasize the importance of the use of proven, behavioral strategies to promote smoking cessation

in pregnancy to ensure optimal outcomes.

Nicotine replacement therapy as a maintenance treatment. *JAMA*, *314*(7), 718–719.

Caffeine.

Caffeine is a widely consumed psychoactive substance. It is a stimulant found in tea, coffee, cola, chocolate, and some OTC medications. Caffeine is an addictive substance. Gene mutations have been found in laboratory animals exposed to moderate amounts of caffeine; however, these defects have not been found in human beings. One study found an association between excess caffeine intake (> 300 mg daily) and a higher risk of low-birth-weight infants (James, 2015). Until additional research clarifies the relationship between caffeine intake and fetal effects, nurses should teach pregnant women to avoid excess caffeine intake.

Chemical Substances

The influence of chemicals on human development remains unclear. Some natural substances found to be teratogenic in animals, but not necessarily in human beings, include insect and bacterial toxins, insecticides, herbicides, and fungicides, including dichlorodiphenyltrichloroethane (DDT). Fish is a source of several nutrients that are important during pregnancy for healthy fetal development, including iodine, omega-3 polyunsaturated fatty acids, and vitamins A, D, and B_{12}. Recent studies involving pregnant women who eat large amounts of fish with high mercury levels (shark, swordfish, king mackerel, canned tuna, or tilefish) support evidence that mercury negatively affects fetal development, particularly brain development, and may be associated with preterm labor (Starling et al., 2015). Women can safely eat up to 12 ounces of cooked fish weekly. Some studies report stillbirths, abortions, preterm births, and mental retardation in fetuses exposed to lead. This area needs more

study, particularly with more women working in traditional male workplaces where there are environmental contaminants. Nurses assess and provide women in their first trimester with information on environmental agents that are potentially damaging throughout gestation and counsel them on ways to avoid exposure.

Medications Given During Childbirth

The final time that the fetus encounters drugs through the mother is during the birthing process. Many women desire medications for labor discomforts, and usually only medications deemed safe and monitored closely during labor and birth have been used (e.g., epidural anesthetics, opiate agonists in small doses). Some analgesic drugs administered during labor can cause neonatal sedation and respiratory depression and can influence the rate and quality of the infant's adaptation to extrauterine life. Studies of visual attentiveness and sucking behavior, as well as neurological tests and electroencephalography, suggest that fetal depressant effects may last as long as days after birth (Halpern & Garg, 2015).

Mechanical Forces

The amniotic fluid reservoir protects the fetus during pregnancy and during mild to moderate trauma to the mother's abdomen. However, major trauma to the mother's abdomen, such as that sustained in a severe car accident, may cause maternal bleeding, preterm labor, and other concerns. The nurse instructs the pregnant woman in the proper way to wear both a lap belt and a shoulder harness to protect her and her fetus while driving. All women in the second and third trimesters should be encouraged to seek medical care following an accident believed to influence the health of mother or fetus.

The uterus, another mechanical force, also influences the fetus. Near the end of pregnancy, the fetus outgrows the uterus and becomes molded by it, particularly in cases of multiple pregnancy. Some children have congenitally dislocated hips from uterine pressure and fetal position in utero. Most deformities resolve either naturally or

with repositioning after birth. Fetal malposition cannot be prevented; therefore the neonate is assessed for problems and support is provided to the parents about the newborn's appearance.

The actual labor and birth process represents the final mechanical force. Few newborns experience injury during this process, and those who do usually recover with limited effect. It is difficult to predict and prevent birth traumas, such as when delivery of an infant who is larger than expected requires vacuum extraction, which may injure the child. In these cases, on the basis of health care team assessment, the mother may undergo cesarean section to protect herself and the baby.

Radiation

Radiation exposure during pregnancy has been debated for years, but various experiences are continuing to show that there are increasingly negative effects on the growing fetus, as well as effects later in life. Scientific evidence indicates that exposure to X-rays, especially early in pregnancy during organogenesis, may cause chromosomal changes, spontaneous abortion, growth restriction, microcephaly, fetal loss, or malignancy later in life (Abdalla & Elshikh, 2015). The fetus is most sensitive to radiation effects between 8 and 15 weeks of pregnancy, and thus should be spared any radiation exposure during that period (Gök et al., 2015). The literature supports a greater incidence of leukemia in children of women exposed to X-rays during pregnancy compared with children whose mothers were not exposed. Unless the benefits of radiographic information clearly outweigh the risks of exposing the fetus to X-rays, these examinations should not be performed during gestation. If radiography is deemed necessary, the wearing of a lead apron, use of as low a radiation dose as possible, and application of other recommendations made by the National Council on Radiation Protection and Measurements should be used to protect the developing fetus.

Determinants of Health

Social Factors and Environment

Community and Work

Women now constitute a significant portion of the workforce. Many more women now work outside the home, either in careers or in jobs needed for family economic survival. As each woman considers or experiences pregnancy, she will need to ask herself questions that will optimize her pregnancy outcome. These questions include the following: Is my work strenuous or possibly dangerous to my baby because of exposure to toxic substances? Do I need to work for long periods, influencing my need for rest? Will workplace stressors influence my coping with pregnancy and my family needs?

A safe workplace environment (one that does not involve exposure to hazardous substances or organisms and provides adequate breaks for worker rest and body movement) will allow a pregnant woman to work until her baby is due, unless her health becomes impaired. The nurse helps each woman assess the safety of her workplace and suggests ways to decrease hazards in that setting. These hazards include exposure to viruses, fungi, industrial products (hydrocarbons or pesticides), second-hand smoke, radiation emitted by medical diagnostic equipment, air pollutants, and asbestos and the possibility of workplace violence, mental and physical stress, and even noise pollution. The nurse encourages the pregnant worker to consider workplace ergonomics, addressing how the current work space will meet her changing physical needs.

Some employers in the United States have been designated creators of "family friendly" work environments, because they have willingly made accommodations to support breastfeeding and pregnant workers and their families. These accommodations allow women to prioritize their pregnancy and family needs. Evidence indicates that such approaches reduce pregnancy complications and increase work productivity. Although few in number, family friendly employers

offer health-promotion programs focusing on healthy nutrition, stress management, and exercise for employees, who experience better health outcomes.

As a rule, however, too few employers support flexible work schedules for prenatal care visits, rest periods for pregnant workers, or removal of vending machines to support optimal nutrition for pregnant working class women. Some working women, regardless of status, believe that once they announce their pregnancy, they will face workplace pressure to stop working or change positions in the company to suit their gestational needs. On the basis of experience, some employers fear that their pregnant employees will overuse sick time or seek a reduced workload.

In a recent study of pregnancy within the workplace, two factors were identified that may be challenging. In many workplaces, pressures on women to "ignore" pregnancy and to "push on" through sickness and exhaustion may relate to certain workplace cultures referred to as "male norms." The partiality for male norms could be seen as creating problems for these pregnant women, who feel obliged to downplay their "inherent femaleness" by minimizing their pregnancy so as to fit in with workplace notions of reliability and presence.

Secondly, health advice on pregnancy might also be difficult to implement within women's workplaces because of underlying assumptions, reflected in health advice, that women's care is most appropriately performed in the home. It is significant that health guidance on pregnancy care work makes little reference to place and offers slender guidance on how pregnancy care work might be implemented at work. Common sense suggests that instructions about napping during the day and using ice packs to relieve hemorrhoids would be entirely inappropriate within most workplaces, whatever the occupation of the pregnant woman (Fox & Quinn, 2015).

Research suggests that pregnant women are discriminated against in the workplace and that a significant number of new mothers leave the workforce. The pregnant woman must deal with these situations by being factual and assertive about her ability to continue working.

National law dictates that it is illegal to discriminate against a woman because she is pregnant. If a woman believes that she has been treated unfairly because of her pregnancy, she may pursue the issue legally or become active in local women's rights organizations to gain support. However, when a woman leaves a job that did not support her pregnancy, she often gives up accrued leave time or takes a lower salary in another job. These outcomes influence her choices during pregnancy and early parenting.

Workplaces differ greatly in allowing leave time during and after pregnancy. Federal legislation, the Family and Medical Leave Act, obligates employers of at least 50 people to provide up to 12 weeks of paid leave for new parents or women who have medical problems during pregnancy. Ideally a woman who desires children should explore the issue of leave during a job interview, but many women fail to do this until they are already pregnant. A woman often requires written verification from her physician if she needs a leave of absence from her job attributable to pregnancy complications. Although she may wish to return to work shortly after giving birth, the woman is counseled to allow sufficient time to regain her strength and adapt to parenting. The nurse may help the couple make reasonable decisions related to locating resources for child care, exploring "shared time" with other new mothers or part-time employees (e.g., middle-age adults caring for their older parents), or finding ways of balancing work and family needs.

Culture and Ethnicity

With the increasing diversity in the United States populations, nurses are challenged to develop culturally competent skills that meet the social, cultural, and linguistic needs of those for whom they care. Cultural competence is not static and requires frequent relearning and unlearning about diversity. Nurses must acknowledge the implications of their own "cultural lens" and continuously reflect on their own assumptions, biases, and stereotypes. Nurses must adopt an attitude of open-mindedness and respect for all cultures. Cultural groups have unique ideas and beliefs related to pregnancy, childbirth,

and childbearing that must be understood by the nurse so as to render individualized care to each pregnant woman. As part of the assessment, the nurse determines the cultural attachment of a woman by asking the following question: Do you think that some or most of the childbearing ideas of your culture are old-fashioned, and do you feel obligated to follow these ideas, at least superficially, because of family pressure? In this situation, the nurse may need to be a confidant for the woman who needs to vent her frustrations about cultural restrictions.

Nonconscious stereotyping and prejudice contribute to racial and ethnic disparities in health care. Contemporary training in cultural competence is insufficient to reduce these problems because even educated, culturally sensitive nurses can activate and use their biases without being aware they are doing so. Research in social psychology shows that over time stereotypes and **prejudices** become invisible to those who rely on them. Automatic categorization of an individual as a member of a social group can unconsciously trigger the thoughts (stereotypes) and feelings (prejudices) associated with that group. This implies that, when activated, implicit negative attitudes and stereotypes shape how nurses evaluate and interact with minority groups. This makes minority group care recipients uncomfortable and discourages them from seeking or adhering to treatment (Tucker et al., 2015).

Nurses need to be very cognizant of their stereotyping and prejudices and "park them at the door-stop" before interacting with minority women. Have nurses ever thought about why pregnant women do not seek prenatal care or do not return for follow-up care once they have encountered a negative reception? If nurses would reverse roles with minority women and just imagine how it feels to encounter negative attitudes when needing health care, perhaps biased attitudes would change dramatically (Villarreal, 2015).

Nurses need an awareness of how culture, tradition, and acculturation may affect the women for whom they provide care, as this is the first step toward understanding diverse cultural behavior. The next step is for nurses to be aware of the three "levels" of culture

when offering health advice and planning health care for various diverse groups:

- The *primary* level of culture refers to rules that are known by all and obeyed by all and may be almost unconsciously performed by women (e.g., health, healing and health-belief systems, or how illness, diseases, and their causes are perceived by that specific culture).
- The *secondary* level is the underlying rules and guidelines known by the group but not generally relayed to outsiders. This may include taboos and rituals relating to behavior, which may be followed depending on the individual.
- A *tertiary* level is visible to the outsider, such as traditional dress, foods, and religious ceremonies (Darnell & Hickson, 2015).

Intercultural caring by nurses is complex. However, nurses need to have a positive attitude and demonstrate acceptance of different cultures. This can be achieved by nurses taking the stance of respecting and understanding diversity, as well as acknowledging any barriers such as culture. Nursing support may assist the individual in adjusting both her needs and those of the culture she represents to experience a satisfactory pregnancy.

The nurse has an obligation to read about and seek information on cultures encountered in practice and to become active in community organizations that represent cultures whose members get prenatal care from the nurse. Above all, the nurse must be open to a variety of viewpoints, judging them not against personal beliefs but rather in relation to the general concept of health promotion and today's goal to provide culturally competent care to a variety of cultural groups. All nurses want to deliver care that is inclusive, that is sensitive to the care seeker's and the family's needs, and that respects the values of their health beliefs and practices. To do this, nurses need to learn about the most common minority cultures with which they interact (Box 16-11: Diversity Awareness).

Box 16-11

Diversity Awareness

Nursing Roles in Providing Culturally Competent Care

In recent years, greater emphasis has been placed on nurses recognizing and appreciating **diversity** so as to acquire cultural competency. Cultural knowledge is the most important construct of cultural competence for nurses, being crucial for the accurate appreciation of a care recipient's worldview. Delivery of culturally competent care implies that a nurse acknowledges and acts on the unique history that a pregnant woman and her family bring to a health care interaction. The essence of both the client centeredness and competence for the nurse is the importance of seeing the woman as a unique individual. The nurse supports culturally competent care by:

- Recognizing that cultural diversity exists and affects the process and outcome of health care
- Respecting people as unique individuals who, by their differences from the majority, bring a broadened definition of appropriate health care
- Using data gained from a cultural assessment for completion of a care plan
- Encouraging cultural behavior that protects the biopsychosocial, spiritual, and safety needs of the individual
- Gaining insight into the nurse's own beliefs and values about people who may be different from or have needs different from those of the majority or those of the nurse's own culture; understanding how these beliefs and values influence the outcomes of health care delivery with childbearing families

- Recognizing the values of the health care system reflected in the customs and practices of birthing facilities
- Providing interpreters to improve communication between the individual and health care providers
- Becoming literate in languages, customs, and cultural practices of people commonly seen in the health care environment
- Developing cultural humility by maintaining an interpersonal stance as it relates to the other person from a different culture
- Recognizing and valuing the diversity of those seeking care and entering all therapeutic relationships acknowledging that nurses are always in the process of learning and growing

Critical reflection in cultural competence development: A framework for undergraduate nursing education. *Journal of Nursing Education*, *55*(3), 125–132.

Levels of Policy Making and Health

Both legislative actions and social movements influence childbearing. In some countries, such as China, the government decrees the number of children a couple may have and imposes economic or social sanctions to enforce these restrictions. Although Americans may have as many children as they desire, various coalitions lobby strongly for families. The Family and Medical Leave Act validates the federal government's commitment to prioritizing family issues by giving new parents time off from work during the early months of parenthood, while supporting these individuals' professional work goals and needs.

The US government remains concerned about the health of pregnant women and ways to decrease fetal and infant morbidity and mortality. Historically, states have used federal monies from Medicaid and Title V maternal and child health block programs to provide services for pregnant women and children. Many countries provide

universal access to prenatal care, but in the United States low-income women rely on Medicaid, a joint federal-state program, to cover most of the cost of prenatal care. With constraints on state and federal budgets, many of which fund community prenatal clinics, concerns have been expressed about whether there will be sufficient money to fund women and children's care programs. Local health departments may offer free or low-cost prenatal care for women who are pregnant, but again the extent of services depends on state government or local allocation of funds. Despite this free or low-cost care and Affordable Care Act health insurance with subsidies, more than 36 million Americans lack health insurance and therefore face barriers that affect their easy access to prenatal care (Levy, 2015; USDHHS, 2010). Many ethnically diverse populations, and in particular Hispanic groups, lack insurance and a level of education that increases their understanding of health-related information (low health literacy) for family health promotion. Educating women during the childbearing cycle is particularly important to increase the chances of families obtaining and understanding health-promotion information for healthier behaviors (USDHHS, 2010).

With the nurse's help in data collection, consumers should be encouraged to express their views and opinions on pregnancy and parenting topics to their elected governmental representatives. This expression indeed works; many states recently legislated hospital stays of at least 48 hours for women with vaginal deliveries and even longer stays for women with cesarean deliveries. These laws evolved from public concern over premature discharges of new mothers as part of managed care insurance directives. Longer stays help health care providers identify potential problems in the mother or the baby before discharge, such as difficulty breastfeeding. Continued legislative work on insurance reform may improve family planning services so that couples can plan pregnancies to better meet their sociocultural and financial goals and needs (USDHHS, 2010). The Patient Protection and Affordable Care Act of 2010 was the most sweeping health care legislation in a generation and impacted women's health tremendously. Insurance reform, driven by legislative

change, may also improve health care coverage for underinsured individuals who lack a consistent source of prenatal care or report difficulties in receiving care because of communication, structural, or personal barriers within their insurance system (Armstrong, 2015).

Economics

When the pregnant woman begins prenatal care, personal financial resources influence the kind of care she receives, the need to remain employed during or after a pregnancy, the acceptance of her pregnancy, her nutritional status, and other choices. The expenses of planning and experiencing a pregnancy may determine whether the woman or her family faces a financial crisis. The nurse needs to understand the financial history and priorities of the couple because this information will affect access to and use of prenatal care.

The nurse inquires in a sensitive fashion about a woman's or a couple's finances to make appropriate referral to resources for care (e.g., Title V or Medicaid programs). Until recently, Medicaid provided no adolescent family planning services, a situation that may have influenced high rates of pregnancy in some sectors of this country (USDHHS, 2010). Many low-income women qualify for the USDA's Special Supplemental Nutrition Program for Women, Infants, and Children. This program provides essential foods such as milk, cheese, and eggs to pregnant and lactating women. During prenatal visits, the nurse may help a woman or family plan a budget for food and other essential requirements based on individual family needs, cultural values, the need for a healthy diet during pregnancy, and income level. Local food banks and second-hand clothing and baby supply stores may provide needed items for these families. Occasionally women may access free transportation and child care at the prenatal clinic if the nurse provides information about this program.

Health Services/Delivery System

Options for care during pregnancy range from medical-based care by

a health care professional to more health-promotion–focused care by a nurse practitioner or midwife. Globally, 80% of people alive today have been born with the assistance of midwives (Midwives Alliance of North America, 2015). Midwives have a long tradition that includes watchful waiting, sharing empirical knowledge, protecting the normal, nonmedicalized birth process, and engaging in research to incorporate the findings into evidence-based practice. Midwifery is distinguished by characteristics that define a partnership with women by listening, being sensitive to cultural, sexual, and generational needs, encouraging shared decision-making, and practicing patience to be "with women" during their most vulnerable periods (King et al., 2015). Several national organizations provide oversight for practicing midwives. The American College of Nurse-Midwives [ACNM] is the professional association that represents certified nurse-midwives and certified midwives in the United States to set the standards in midwifery education and practice (ACNM, 2015). The National Association of Certified Professional Midwives [NACPM] is the membership organization specifically representing certified professional midwives to be a powerful voice to influence maternity health policies (NACPM, 2015). Geographical availability of options, finances, previous experience, partner's preference, cultural or social acceptability of certain options, and preexisting or newly recognized risk factors will influence a woman's choice of care. Because of her culture and the belief that pregnancy is not an illness, a woman may not seek Western medical prenatal care, but rather may rely on individuals from her culture to provide care until the actual labor, when she will go to a hospital.

Unless complications arise a woman generally chooses where she will labor and give birth and the extent of labor and birthing process intervention. The movement toward home birth that began during the early 1970s continues to meet some women's needs for a more family-oriented, natural, health-focused experience. However, most couples choose a hospital birth setting because of the availability of emergency equipment and personnel in the case of complications. Some insurance companies will reimburse only births that occur in hospitals

and in birth centers or birthing rooms attached to a hospital. The nurse helps expectant couples become aware of the care and birthing alternatives to make an informed choice for a positive labor and birth experience. Women who lack resources to access the health care delivery system and teaching by the nurse during regular prenatal visits are generally less able to make informed decisions that affect their childbearing experiences.

Many expectant couples also make an informed choice about the actual process of labor and birth by developing a birth plan—those components of care and intervention that the couple desires for the birth experience. A pregnant woman and her partner may choose natural childbirth or a method of analgesia or anesthesia. The nurse helps the pregnant woman and her partner choose the most appropriate method by providing information about options and encouraging questions about each option. Collaboration between the nurse and the woman or couple in meeting their birth plan goals is important because research shows that women remember their labor and birthing experiences for a long time. A positively viewed birth experience may support a couple's involvement as active health care consumers, thus facilitating the future health of their family.

The nurse may encourage the pregnant couple or woman to attend prenatal classes. These provide valuable information and preparation for birth for many couples. The International Childbirth Education Association, the American Society for Psychoprophylaxis in Obstetrics (ASPO), and many local groups offer a variety of classes for the expectant couple. These classes may include information on early pregnancy, Lamaze-ASPO or Bradley methods, cesarean birth, breastfeeding, infant cardiopulmonary resuscitation, and parenting. Sibling classes for the newborn and involvement of children in the birth experience may also increase sibling bonding.

Nursing Application

Teaching the pregnant woman and her partner during the prenatal period is the most important role of the nurse. Even the woman who has previously given birth or who has a high degree of education may need or want information from the health care team that will assist her family to adapt effectively to changes of pregnancy to support a healthy birth outcome.

To provide appropriate teaching, the nurse performs a comprehensive assessment that involves the entire family. Assessment, the first step in the nursing process, allows the nurse to determine maternal and fetal physical and psychological risks, the woman's informational base for pregnancy and birth, and cultural and family needs. Assessment should also include physical, spiritual, emotional, and sociocultural inspection and recognition of abuse. Battering increases during pregnancy and may be detected by physical, emotional, behavioral, and history assessment of the woman. Pregnant women at high risk of abuse include adolescents, those with low incomes, and those with a history of alcohol or drug abuse, as well as those with a partner with a similar history (Bohra et al., 2015; Copelon, 2015). In cases of suspected abuse, the nurse, in consultation with other members of the health care team, provides support and resources for the woman to make an informed decision about protecting herself and her fetus during pregnancy. The nurse may also want to refer the woman to a professional counselor for a brief counseling outreach intervention or abuse shelter for personal safety (Jewkes & Penn-Kekana, 2015).

As discussed in this chapter, assessment may also be made by use of Gordon's (2016) functional health patterns, a common conceptual framework for clinical assessment (see Box 16-5). Data used in the assessment process will likely be collected during the prenatal visit and may change depending on life occurrences of the pregnant woman. A woman may be defined as high risk during her pregnancy if she experiences heavy bleeding, premature labor, elevated blood

pressure, or extreme anxiety; if there is fetal distress; or if the woman shows unexpected behavior or symptoms. After noting these high-risk conditions, the nurse should refer the pregnant woman to an obstetrical specialist or other resources for pregnant women and their families (see the case study at the end of this chapter).

After a complete assessment during each prenatal visit, the nurse develops a teaching plan for the individual. Throughout the prenatal course, the nurse collaborates with the woman and her partner to assess their learning and support needs. For example, literature on bottle feeding or breastfeeding may be provided to help a woman decide on a method, and books, videos, and websites may help couples understand more about birth and therefore feel that they have more control during labor and in meeting their birthing goals. If the woman plans to attend group prenatal classes, the nurse should coordinate her teaching content and process with those expected in the classes, thereby preventing undue repetition. The nurse teaching prenatal classes should provide a list of topics to participants in the class to share with their health care providers. A woman may be knowledgeable in some areas, and the nurse can use this knowledge as a foundation for further individualized teaching. Box 16-12 covers relevant topics to be covered by the nurse during prenatal care interactions with pregnant women. These topical areas relate to nursing interventions discussed earlier in this chapter. Basic handouts detailing danger signs of pregnancy can be posted in the home to consult if the woman experiences unexpected complications of pregnancy.

Box 16-12

Topics for Prenatal Care Teaching

- Rationale for and interpretation of physical findings and laboratory results
- Value of keeping appointments

- Danger signs that should be reported
- Breast care to prepare for lactation
- Breastfeeding versus bottle feeding
- Exercise and rest
- Fetal growth and development
- Physical and psychological changes during pregnancy and relief measures
- Effects of smoking, drinking, and drugs on the fetus
- Nutrition
- Work and play
- Body mechanics
- Personal hygiene
- Sex during pregnancy
- Preparation for labor and birth
- Superstitions and old wives' tales
- Signs of impending labor
- Supplies and preparations for the baby
- Partner's and siblings' responses

Case Study

Active Labor: Susan Wong

Mrs. Wong, a first-time mother, is admitted to the birthing suite in early labor after spontaneous rupture of membranes at home. She is at 38 weeks of gestation with a history of abnormal alpha-fetoprotein levels at 16 weeks of pregnancy. She was scheduled for ultrasonography to visualize the fetus to rule out an open spinal defect or Down syndrome, but never followed through. Mrs. Wong and her husband disagreed about what to do (keep or terminate the pregnancy) if the ultrasonography indicated a spinal problem, so they felt they did not want this information.

Reflective Questions

- As the nurse, what priority data would you collect from this couple to help define relevant interventions to meet their needs?
- How can you help this couple if they experience a negative outcome in the birthing suite? What are your personal views on terminating or continuing a pregnancy with a risk of a potential anomaly? What factors may influence your views?
- With the influence of the recent Human Genome Project and the possibility of predicting open spinal defects earlier in pregnancy, how will maternity care change in the future?

Prediction of Human Disease

An organism's complete set of DNA is called its genome. Virtually every single cell in the body contains a complete copy of the approximately 3 billion DNA base pairs, or letters, that make up the human genome. The Human Genome Project (completed in 2003), conducted by the National Human Genome Research Institute, produced a very high-quality version of the human genome sequence that is freely available in public databases. Researchers have been able to use DNA sequencing to search for genetic variations and/or mutations that may play a role in the development or progression of a range of diseases. Clearly, there are implications and ethical

considerations for the health sciences here. Along with the important information uncovered by the Human Genome Project, a great controversy arose. Even though blood tests are now available for the detection of various fatal diseases such as Huntington disease, cystic fibrosis, and colon cancer, many people would rather live with uncertainty than know they have an incurable life-threatening disease. Sadly, the tests, which have been developed, are to detect the disease and not cure it.

Another consideration is the use of genetic information by existing and prospective employers. Imagine a situation where employment preference is given to those who can demonstrate they are "genetically free" of future diseases that might limit their capacity to work. Still, three major unsolved problems in perinatal and neonatal health are preterm birth; the neonatal consequences of vaginal versus cesarean birth; and neonatal gastrointestinal disease, specifically necrotizing enterocolitis. Hopefully soon, the Human Genome Project's research will be able to address all three to improve pregnancy outcomes.

In just 1 decade, the Human Genome Project has sparked an explosion of information that has proved useful to basic and clinical scientists. We must remain cautious as to how and when this new information and technology are used in the future to ensure they are used for the betterment of humankind.

Care Plan

Nursing Management for Stages of Labor: Susan Wong

***NURSING DIAGNOSIS: Ineffective coping related to active labor status**

Defining Characteristics

- Initiation of labor at 2:00 a. m. with spontaneous rupture of

membranes

- First-time mother who did not attend childbirth classes
- Supportive spouse
- Current gestational age of 38 weeks
- Contraction pattern defined as moderate intensity, frequency every 2 minutes, 60 seconds in duration
- After 6 hours of labor, 4 cm dilated, 100% effaced, and stage active phase
- Moaning, moving around in bed, and stating, “I can't take this much longer; it hurts too much!”

Related Factors

- Prenatal history of abnormal alpha-fetoprotein levels at 16 weeks
- Prenatal care since 12 weeks pregnant
- History of depression in college
- Works as an engineer with large manufacturing firm
- Gravida 1, parity 0
- Recent resident of city, moved from East Coast approximately 4 months ago
- 25 years of age, Asian family history, married for 1 year

Expected Outcomes

- Mother will state level of pain to be less than 4 on a scale of 1 to 10

during labor.

- Mother will successfully use visual imagery techniques, massage, and slow deep breathing for relaxation during labor.
- Mother will state early in labor at least three ways to cope effectively with pain and will implement these strategies as relevant.
- Fetus will demonstrate an expected heart rate pattern and will experience no compromise during labor.
- Mother and family will verbalize their needs during labor and delivery to the health care team.

Interventions

- Assess level of labor discomfort every 20 to 30 minutes and as needed according to pain scale rating of 1 to 10.
- Implement and document nursing interventions (backrubs, heat and cold applications, position changes, back pressure and massage, and birth pool therapy, among others) to relieve labor discomforts.
- Assess cultural beliefs with labor and delivery management and implement interventions as needed to meet practice standards.
- Provide teaching about labor and delivery progress and breathing, visual imagery, and massage techniques that may decrease labor discomfort.
- Provide verbal and nonverbal reassurance during labor.
- Teach about fetal response during labor and rationale for nursing interventions to support fetal health, such as use of left side position to increase placental blood flow.
- Throughout labor, answer any questions from the mother and

family members about needs and responses to labor process.

- Involve family members as much as possible during labor and as requested by the mother to improve her ability to cope.

---

Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Dramatic changes occur during pregnancy: a new life forms and develops and the expectant family members (mother, father, siblings, and other close members) experience major changes in their roles and relationships with each other. Although all fetal development processes, changes in pregnant women's bodies, and role transitions among family members share common elements, each family uniquely experiences pregnancy because of life experience and personal values. The focus is the entire family, although the nurse most often deals directly with the pregnant woman. The nurse provides valuable resources and information that the family may use to meet its specific needs. The overall nursing goal involves assisting each family to have a healthy pregnancy and birth outcome, to lay the foundation for satisfactory parenting and family life.

Infant

Susan Scott Ricci

OBJECTIVES

After completing this chapter, the reader will be able to:

- Evaluate the infant's health status and give examples of basic growth and developmental principles.
- Analyze the developmental tasks for the infant and the behavior indicating that these tasks are being accomplished.
- Explain the immunization schedule and other safety and health-promotion measures to a parent.
- Detect common parental concerns about infants and describe a model for parent education to allay these concerns.
- Examine accidents that occur during infancy and recommend appropriate counseling for accident prevention and safety.
- Differentiate ways in which nurses can be active in promoting major policies and influencing legislation concerning health.
- Outline governmental strategies to meet the goals of improving infant health.

KEY TERMS

Active immunization

Birth defect

Body mass index

Infant/child abuse

Growth

Growth index

Oral stage of development

Passive immunization

Paternal engrossment

Poor growth

Sickle cell anemia

Sudden infant death syndrome

Tay-Sachs disease

Trust versus mistrust

Weaning

Think About It

Car Safety Seats

Infants are at particular risk in automobile accidents. The proper use of occupant protection systems (infant car safety seats with seat belts) can reduce the risk of death and injury significantly. Although many public service campaigns encourage parents to restrain their infants while riding in automobiles (and all states have laws requiring some type of passenger safety restraint for infants), some parents neglect or remain unaware of the importance of providing safety for their vulnerable infants.

Nurses must have up-to-date knowledge of car occupant protection systems and their proper use to help parents find new products and obtain the most current information available. Parents often rely on the person selling the infant car seat for their information about protection systems and the proper use of car seats. However, informational brochures and media campaigns fall short because they usually fail to provide explanations or

demonstrations. As a result, parents may misinterpret the information that they receive.

- What type of program might you develop to reach and inform parents about the importance of car seat safety?
- In what settings might such a program be implemented?
- How would you modify your teaching plan to meet the needs of illiterate parents?
- How would you modify your program to ensure that parents who come from cultural backgrounds different from your own would respond well to the information?

Infants are recognized as the most vulnerable and dependent members of society, and their well-being is often used to measure the overall health of society. Health is shaped by a broad set of determinants, including socioeconomic status, physical and social environments, genetics and biological influences, and access to health care. Providing a safe and sound source of attachment and interaction is paramount to healthy infant development. Caregiving and mothering activities are the primary ingredients of an infant's preparation for life and ultimate independence. Nurses play a vital role in influencing this positive interaction through health promotion and education.

This chapter focuses on the infant and the infant's family during the infant's developmental period of 1 to 18 months. Because the infant is completely dependent on others, this chapter addresses the infant's parents and significant others as sources of health-promotion activities. The relationship initiated at birth between parents and the infant is the basis for the interdependence that is required for proper psychological and physical infant development. Health care professionals must focus on parent education as a means of fostering healthy, satisfying relationships within the family unit, and promoting the development of healthy future generations.

The principles of normal growth and development are used as a structural framework for this chapter. Understanding these principles helps the nurse identify deviations from the norm and institute appropriate health-promoting interventions.

To promote and maintain health during infancy, a balance between the infant's internal and external environmental forces must be established; any disruption places the infant at risk. Several processes that greatly influence this balance are identified, and appropriate interventions are outlined to assist the nurse in promoting a healthy infant population (American Academy of Pediatrics [AAP], 2015a; Ma et al., 2015) (Box 17-1: *Healthy People 2020*).

Box 17-1

Healthy People 2020

Selected National Health-Promotion and Disease-Prevention Objectives for Infants

- MICH-1.3: Reduce the rate of all infant deaths (within 1 year). Target: 6.0 infant deaths per 1000 live births (baseline: 6.7 infant deaths per 1000 live births within first year of life in 2006—10% reduction).
- MICH-1.4: Reduce the rate of neonatal deaths (within the first 28 days of life). Target: 4.1 neonatal deaths per 1000 live births (baseline: 4.5 neonatal deaths per 1000 live births occurred within the first 28 days of life in 2006—10% reduction).
- MICH-1.6: Reduce the rate of infant deaths related to birth defects (all birth defects). Target: 1.3 infant deaths per 1000 live births (baseline: 1.4 infant deaths per 1000 live births were attributed to birth defects [all birth defects] in 2006—10% reduction).
- MICH-1.8: Reduce the rate of infant deaths from SIDS. Target: 0.50 infant deaths per 1000 live births (baseline: 0.55 infant deaths per

1000 live births were attributed to SIDS in 2006—10% reduction).

- MICH-2: Reduce the 1-year mortality rate for infants with Down syndrome. Target: 43.7 deaths within the first year of life per 1000 infants with Down syndrome (baseline: 48.6 deaths within the first year of life per 1000 infants with Down syndrome occurred from 2005 to 2006—10% reduction).

- MICH-20: Increase the proportion of infants who are put to sleep on their backs. Target: 75.9% (baseline: 69.0% of infants were put to sleep on their backs in 2007—10% increase).

- MICH-21: Increase the proportion of infants who are breastfed. Target: 81.9% (baseline: 74.0% of infants born in 2006 were ever breastfed as reported from 2007 to 2009—10% increase).

From US Department of Health and Human Services. (2010). Healthy People 2020. http://www.healthypeople.gov/2020/topicsobjectives2020/objectiveslist.aspx?topicId=26.

Biology and Genetics

Human development begins when a single sperm penetrates a mature ovum. The changes that follow are undeniable and wondrous. During this early period of growth and development the infant depends completely on others, primarily the parents, to meet all personal needs (Table 17-1). To assist the parents in their understanding of their infant's needs and progress, the nurse must know what behaviors to expect at certain ages. These developmental landmarks serve as a basis for anticipatory guidance (Table 17-2). Parents are aware of age-appropriate behavior to anticipate and facilitate these developmental landmarks. This knowledge, along with the nurse's anticipatory guidance, can also promote closer family relationships. In addition to the growth landmarks, the infant must accomplish developmental tasks to form a healthy personality.

TABLE 17-1

GROWTH AND DEVELOPMENT
During Infancy

1 Month
• Follows and fixes on bright object with eyes when it moves within field of vision • Still has head lag when pulled to sitting position • Displays tonic neck, grasp, and Moro reflexes • Turns head when prone, but unable to support it • Displays sucking and rooting reflexes • Holds hands in fists • Looks intently at caregiver when talked to • Makes small, throaty sounds • Gains 5 to 7 ounces weekly for 6 months • Grows 1 inch monthly for 6 months • Cries when hungry or uncomfortable • Lifts head momentarily when prone
2 Months
• Has closed posterior fontanel • Listens actively to sounds • Lifts head almost 45 degrees off table when prone • Follows moving object with eyes • Grasp reflex decreases • Recognizes familiar faces • Pays attention to speaking voice • Assumes less flexed position when prone

- Vocalizes; distinct from crying
- Turns from side to back
- Begins to have social smile

3 Months

- Visually inspects object and stares at own hand with apparent fascination when either appears in field of vision
- Has longer periods of wakefulness without crying
- Laughs aloud and shows pleasure in vocalization
- Holds head erect and steady; raises chest, usually supported on forearms
- Smiles in response to mother's face
- Recognizes faces, voices, and familiar objects
- Opens and closes hands, shakes toys
- Begins prelanguage vocalizations (coos, babbles, and chuckles)
- Carries hand or object to mouth at will
- Grasp reflex absent
- Follows objects for 180 degrees
- Actively holds rattle, but will not reach for it
- Turns eyes to object placed in field of vision

4 Months

- Begins drooling, indicated by appearance of saliva; does not know how to swallow it
- Holds head steady when in sitting position
- Recognizes familiar objects
- Shows almost no head lag when pulled to sitting position
- Rolls from back to side and from abdomen to back
- Inspects and plays with hands; pulls clothing or blanket over face in play
- Begins eye-hand coordination
- Chews and bites
- Enjoys social interaction
- Demands attention by fussing
- Reaches out to people
- Bears some weight on legs when held upright
- Is aware and interested in new environment
- Grasps object with two hands
- Squeals

5 Months

- Reaches persistently; grasps with entire hand
- Plays with toes
- Begins to discover parts of his/her body
- Smiles at mirror image
- Begins to postpone gratification
- Shows signs of tooth eruption
- Sleeps through night without food
- Weighs twice the birth weight
- Sits with slight support
- Vocalizes displeasure when desired object is taken away
- Is able to discriminate strangers from family members
- Makes cooing noises
- Squeals with delight
- Looks for object that has fallen
- Rolls from back to stomach or vice versa

6 Months

- Gains approximately 3 to 5 ounces weekly during the second 6 months
- Grows approximately 1 inch monthly for 6 months
- Is able to lift cup by handle
- Begins to hitch in locomotion
- Sits in high chair with straight back

- Begins to imitate sounds
- Vocalizes to toys and mirror image
- Recognizes caregivers
- Babbles with one-syllable sounds: “ma, ma, da, da”
- Chewing and biting occur
- Has definite likes and dislikes
- Likes to be picked up
- Plays peek-a-boo
- Makes “guh” and “bah” sounds

7 Months

- Has eruption of upper central incisors
- Bears weight when held in standing position
- Sits, leaning forward on both hands
- Fixates on one very small object
- Produces vowel sounds: “ba-ba” and “da-da”
- Shows fear of strangers
- Displays emotional instability by easy and quick changes from crying to laughing
- Repeats activities that are enjoyed
- Bangs objects together
- Develops taste differences
- Transfers objects from one hand to another
- Approaches toy and grasps it with one hand
- Imitates simple acts

8 Months

- Feeds self with finger foods
- Sits well alone
- Stretches out arms to be picked up
- Greets strangers with bashful behavior
- Begins to show regular patterns in bladder and bowel elimination
- Responds to “no” but does not obey it
- Makes consonant sounds: t, d, and w
- Dislikes dressing and diaper change
- Releases object at will
- Shows nervousness with strangers
- Pulls toy toward self

9 Months

- Creeps and crawls (backward at first)
- Shows good coordination and sits alone
- Responds to adult anger; cries when scolded
- Explores object by sucking, chewing, and biting it
- Responds to simple verbal requests
- Drinks from cup or glass with assistance
- Pulls self to standing position
- Begins to show fears of going to bed and being left alone
- Imitates waving “bye-bye”
- Sits for prolonged periods—10 minutes
- Releases object with flexed wrist
- Repeats facial expressions of adults
- Uses thumb and index finger in pincer grasp

10 Months

- Sits by falling down
- Says “da-da” and “ma-ma” with meaning
- Understands “bye-bye”
- Looks at and follows pictures in book
- Object permanence begins to develop
- Plays interactive games such as pat-a-cake

- Crawls and cruises about well
- Pays attention to own name
- Picks up objects fairly well
- Extends toy to another person without releasing
- Pulls self to standing position and stands while holding onto solid object

11 Months

- Is able to push toys and place several objects in container
- Attempts to walk without assistance
- Begins to hold spoon
- Explores objects more thoroughly
- Stands erect with help of person's hand
- May have eruption of lower lateral incisors
- Holds crayon to mark on paper
- Acts frustrated when restricted
- Imitates definite speech sounds
- Reacts to restrictions with frustration

12 Months

- Loses Babinski sign
- Understands simple verbal commands

- Develops evident hand dominance
- Weighs triple the birth weight
- Has equal circumference of head and chest
- Walks with one hand held
- Knows own name
- Turns pages in book
- Has slow vocabulary growth because of increased interest in walking
- Develops lumbar curve
- Uses spoon in feeding, but often puts it upside down in mouth
- Drops object deliberately for it to be picked up
- Shakes head for “no”
- Plays pat-a-cake
- Recovers balance when falling over
- Tries to follow when being read to
- Does things to attract attention
- Imitates vocalization lead

15 Months

- Creeps up stairs
- Uses “da-da” and “ma-ma” labels for correct parents
- Tolerates some separation
- Drinks from cup well, but rotates spoon
- Asks for object by pointing
- Plays interactive games such as peek-a-boo and pat-a-cake
- Expresses emotions; has temper tantrums
- Walks without help

18 Months

- Has closed anterior fontanel
- Has long trunk, short and bowed legs, and protruding abdomen
- Walks upstairs with help
- Turns pages of book
- Has short attention span
- Begins to test limits
- Has bowel movements at appropriate time when placed on potty
- Indicates wet pants
- Gets into everything
- Fills and handles spoon without rotating it, but spills frequently
- Runs clumsily and falls often

- Is extremely curious
- Places object in hole or slot
- Becomes communicative, social being
- Imitates behavior of parents, such as mimicking household chores

TABLE 17-2

Parenting Tasks for Developmental Landmarks in Infancy

Age (Months)	Landmark	Parenting Task
1	Lifts head when prone	Place infant in prone position and dangle colorful object above its head
2	Has social smile	Promote by talking to infant and allowing opportunity for infant to smile
4	Squeals	Encourage and praise for doing so
5	Rolls from back to front	Place infant in protected area (crib or playpen) and encourage infant to move by placing toy out of reach
8–9	Uses pincer grasp to feed self	Make finger foods available
10	Pulls self to standing position	Provide safe environment; place chair or object of appropriate height within reach
11–12	Initiates vocalization	Talk to infant frequently and include in family gatherings
12–15	Walks	Encourage and provide clutter-free, safe walkway; praise infant for attempts
15	Drinks from cup	Supply cup with appropriate drink; do not scold infant for clumsiness in handling cups or spills
18	Mimics household chores	Give rags to infant to help with chores and dusting, allow infant to fold clothes, and so on

Developmental Tasks

Infant development begins before birth. A healthy pregnancy and a positive early childhood environment are essential to normal infant physical and mental health. Every infant faces developmental tasks and must accomplish them individually. Different practices in various societies affect the perception and resolution of the tasks, but all must

be faced (Berk & Meyers, 2015).

The infant's first and most basic task is survival, which includes the physical tasks of breathing, sucking, eating, digesting, eliminating, and sleeping. Because many of these tasks involve the infant's mouth, this stage of life often is referred to as the **oral stage of development,** reflecting the primary importance of the mouth as the center of pleasure. More developmental tasks that must be accomplished during infancy are listed in Table 17-3. In the first year, infants learn to focus their vision, reach out, explore, and seek out things around them. During this time, infants also develop bonds of love and trust with their caregivers and others as part of their social and emotional development. Nurses can provide the infant's caregivers with guidance to encourage their infant's development by their:

TABLE 17-3

GROWTH AND DEVELOPMENT
Developmental Tasks Accomplished in Infancy

- Achieves physiological equilibrium after birth
- Establishes self as a dependent person, but separate from others
- Becomes aware of animate versus inanimate objects and familiar versus unfamiliar objects and develops rudimentary social interaction
- Develops a feeling of affection for others and the desire for affection from others
- Manages the changing body and learns new motor skills, develops equilibrium, begins eye-hand coordination, and establishes rest-activity rhythm
- Learns to understand and control the physical world through exploration
- Develops a beginning symbol system, conceptual abilities, and preverbal communication
- Directs emotional expression to indicate needs and wishes

From Centers for Disease Control and Prevention. (2016). Developmental milestones. http://www.cdc.gov/ncbddd/actearly/milestones/index.html; The Center for Parenting Education. (2016). Tasks for infants through 18 months. http://centerforparentingeducation.org/library-of-articles/child-development/developmental-tasks/#infants.

- Talking to their infant, especially in a calming fashion
- Repeating sounds that their infant makes to help the infant learn to use language
- Reading to their infant to help develop and understand language and sounds

- Singing and playing music to help the infant develop a love for music and to help with brain development
- Giving their infant a great deal of loving attention to make the infant feel secure
- Praising their infant when something has been accomplished or learned (Centers for Disease Control and Prevention [CDC], 2015a)

To assist the infant's parents in encouraging achievement of these tasks, the nurse discusses the importance of stimulation and environmental interactions. Many neurological structures are far from completely developed at birth (Feldman, 2015). To continue growing, the brain depends not only on internal, embryological, and maturational forces but also on external stimulation. This external stimulation appears to influence the internal, anatomical, and maturational processes by different mechanisms (Bhattacharjee, 2015):

- Stimulation favors progressive complex branching of dendrites (the connection between nerve cells).
- Stimulation increases the degree of vascularization of certain anatomical structures of the brain, such as the centers associated with vision.
- Stimulation through social experiences is the portal to linguistic, cognitive, and emotional development in infants.
- Stimulated infants tend to have higher IQs and better memory as they grow older.
- Stimulation increases the process of myelination, which is closely related to the rate of development of a variety of functions. Myelin coats the brain and nerve tissue, which then becomes activated.

When counseling parents, the nurse stresses the importance of a variety of stimuli within the infant's environment. A variety of auditory and visual stimuli should be available, such as colorful mobiles, radio, spoken voice, and toys, to assist the infant in achieving developmental tasks. The sense of touch is an extremely important stimulus, bringing the infant in tune with caregivers in different environments, making it a reality. Ensuring that appropriate sensory stimuli are available is vital to the infant's growth and developmental

progression (Feldman, 2015).

Concepts of Infant Development

As infants develop, they go through a series of developmental stages that are important for all aspects of their personhood, including physical, intellectual, emotional, and social aspects. The role of their caretakers is to provide encouragement, support, and access to activities that enable them to master key developmental tasks. The study of how a helpless infant grows and develops into a fully functioning, independent adult has fascinated many researchers. Their theories describe the development of human behavior as overlapping stages that occur in somewhat predictable patterns in an individual's life (Child Development Institute, 2015). Because these developmental theories are presented in Chapter 15, only their specific application to the infant is discussed here.

Psychosocial Development

Erikson's psychosocial developmental theory is concerned primarily with a series of tasks or crises that each individual must resolve before encountering the next one. The central task during infancy is the development of a sense of **trust versus mistrust**. This occurs when adults meet an infant's basic needs for survival. The establishment of this basic trust or mistrust determines the manner in which the infant approaches all future stages of growth. The infant develops a sense of trust first in the mother (or other caretaker) and then in other significant people. Trust influences the infant's future relationships, allowing deeper commitment and intimacy. To develop trust the infant requires maximal gratification and minimal frustration to experience a healthy balance between inner needs and outer satisfaction. If the mother or caretaker is consistently responsive to the infant, meeting the physical and psychological needs, the infant will likely learn to trust his or her caretaker, view the world as a safe place, and grow up to be secure, self-reliant, trusting, cooperative, and helpful toward others.

A prompt, skillful, and consistent response to the infant's needs helps foster security and trust because it enables the infant to predict what will happen within the environment. When unpredictability and disorganized routines exist, the infant will develop fear, anger, anxiety, and insecurity, which eventually lead to mistrust. The infant can demonstrate desire by crying but depends on the sensitivity and willingness of others to provide relief. If the most important people fail to do this, the infant has little foundation on which to build faith in others or self in adulthood. If the infant's needs are not met appropriately, the infant will grow up with a sense of mistrust and may view the world as unpredictable.

Cognitive Development

Piaget's cognitive developmental theory focuses on intellectual changes that occur in a sequential manner as a result of continual interaction between the infant and the environment. The theory is based on the idea that infants actively construct knowledge as they explore and manipulate the world around them (Carey et al., 2015). Piaget's **sensorimotor period** (up to age 18 months) describes the time during which infants develop the coordination to master activities that allow them to interact with the environment. During this period the infant solves problems using sensory systems and motor activity rather than symbolic processes, which develop later.

Fetuses are able to distinguish light from dark, and sight is present at birth. Rod cells in the retina of the eyes, which are responsible for light perception, are functional at birth although the retina (the organ of visual perception) is not fully developed until approximately 4 months of age. However, the infant can perceive color and shape. Infants are startled by loud noises and are soothed by soft voices, indicating that their sense of hearing is functioning. Their hearing can also be tested with audio equipment at birth. Babies cry when pricked with a diaper pin and fuss when too hot or too cold; therefore the senses of pain and temperature are also operative. Touching, stroking, and rocking typically comfort a fussing infant. Infants will also react to odors and tastes.

In addition to perceiving stimulation, the newborn is capable of reflexive behavior. **Reflexes** are responses that are normally exhibited after particular types of new stimulation (Moses, 2015). Because the response occurs after the stimulus, reflexes are unlearned. Some infant reflexes, such as rooting and sucking, have survival value. The rooting reflex, activated by the angle of the lips or cheek being lightly stroked, helps the infant locate the food source. The infant will turn toward the side that is being stroked and will open the lips to suck. The sucking reflex is initiated when an object is placed in the infant's mouth. Together these reflexes ensure that the infant can obtain food. Infants also have reflexes that result in grasping, yawning, hiccoughing, coughing, and sneezing.

Armed with these reflexes and sensory capabilities, the infant is ready to begin interacting with the environment (seeing, hearing, touching, tasting, and smelling) to acquire valuable information.

The infant progresses in various ways between birth and age 18 months, with early capabilities changing and becoming intentional. Piaget outlines five stages within the sensorimotor period that describe the infant's development, from the early reflexive behavior to differentiation between self and the environment (Table 17-4).

TABLE 17-4

GROWTH AND DEVELOPMENT
Piaget's Five Stages of Infant Development

Stage	Description
1: birth to 1 month	Modification of reflexes Practices and perfects reflexes present at birth Sucking reflex becomes more refined and voluntary
2: 1–4 months	Primary circular reactions Repeats behavior that previously led to an interesting event Only the infant's own body involved in activities
3: 4–10 months	Secondary circular reactions begin Repetitions involve events or objects in the external world Appears to perform actions with a purpose Hand-eye coordination
4: 10–12 months	Coordination of secondary reactions Combines two or more previously acquired strategies to obtain a goal
5: 12–18 months	Tertiary circular reactions Uses active experimentation to achieve previously unattainable goals Infant purposely varies movements to observe results

From Boundless. (2016). Piaget's stages of cognitive development. *Boundless Psychology.* https://www.boundless.com/psychology/textbooks/boundless-psychology-textbook/human-development-14/theories-of-human-development-70/piaget-s-stages-of-cognitive-development-270-12805/.

The infant in the sensorimotor period uses behavioral strategies to manipulate objects, to learn some of their properties, and to reach goals by combining several behaviors. The infant's behavior is tied to the concrete and the immediate; schemes can be applied only to objects that can be perceived directly.

Knowledge of child developmental theories is extremely valuable to the nurse during interactions with infants. Understanding the infant's level of cognitive thought and emotional and social development helps the nurse decipher a child's communications more meaningfully and interpret behaviors and the processes that motivate the child more accurately. This knowledge can be incorporated in the anticipatory guidance offered to the parents. The nurse stresses that a variety of sensory and motor stimuli foster learning within the infant's environment.

The Infant Development Inventory is an infant assessment tool that screens children from birth to 18 months. It tracks developmental skills in five areas: social, self-help, gross motor, fine motor, and language. Monthly developmental milestones on the development chart help parents obtain a more comprehensive picture of how infants develop. Parents can also report any questions or concerns about their infant's health, development, or behavior. Parents complete the 60-question survey and the tester scores it. Health care providers may also further assess the infant's development by observing behaviors and recording them on the chart, in which case the baby's progress will be scored “typical,” “borderline,” or “delayed” in each developmental area.

The infant's growth index—height and weight measurements plotted on a standard growth chart to assess the infant for normal progression—is also important. Physical growth (height and weight) is a valid health status indicator that should be measured during each routine office or clinic visit. During the first year of life, growth is rapid. An infant who is growing properly is at low risk of developing

a chronic disease (CDC, 2015b).

The nurse plots the infant's length and weight measurements against exact chronological age on growth grids. In 2009, the World Health Organization (WHO) released new international growth charts for children aged 0 to 59 months. It was recommended by the AAP and CDC that the WHO international growth charts be used for children younger than 24 months and that the CDC growth charts be used for children older than 24 months (CDC, 2015b). **Body mass index (BMI)** is a feature of the new pediatric growth charts that have been released by the CDC. BMI is the individual's weight in kilograms divided by the square of height in meters. In infants and children a high amount of body fat can lead to weight-related diseases and other health issues. A BMI calculator for children and teens can be found on the CDC website: http://nccd.cdc.gov/dnpabmi/Calculator.aspx. Growth charts are not intended to be used as a sole diagnostic instrument. Instead, growth charts are tools that contribute to the formation of an overall clinical impression of the child being measured (CDC, 2015c).

With the addition of body mass index to the charts, the CDC significantly increased the usefulness of this tool as a warning signal for potential obesity as early as 2 years of age. Parents have an opportunity to change their children's eating habits before a weight problem develops. The revised pediatric growth charts more accurately reflect the cultural and racial diversity currently found in the United States and can track children and young people through age 20 years. The growth charts indicate that children are heavier today than in the past, but height has remained virtually unchanged.

An infant's **growth index**, as determined by length and weight, is only one factor used in the assessment of health status. Differences in **growth** curves can influence the diagnosis of undernutrition and overnutrition, and the interpretation of adequate growth following nutritional intervention. The nurse has an overall understanding of growth and developmental principles to counsel parents regarding their infant's progress.

Sex

The infant's sex is determined at the moment of fertilization. Immediately after childbirth, the parents may ask, “Is it a girl or a boy?” The answer has far-reaching implications for many family units. Sex is one of the many important factors that influence parents' way of relating to the infant.

There are many biological and behavioral differences between male and female infants. Boys are, on average, larger and have proportionately more muscle mass at birth. Girls are generally smaller but physiologically more mature at birth and are less vulnerable to stress. Boys show more motor activity, whereas girls display a greater response to tactile stimulation and pain (Polan & Taylor, 2015). As the infant develops, further differences are noted. By 6 months, girls respond to visual stimulation with longer attention spans and are more socially responsive than are boys; girls also tend to sit up, walk, and crawl earlier than do boys. Girls also learn to communicate with language at an earlier age, whereas male infants use their whole bodies in communicating (Kail & Cavanaugh, 2015).

The sex of the infant, a major concern of many expectant parents, may well influence parental relationships and expectations. The infant's sex can evoke disappointment; in some cases, a woman may feel disappointed in a girl because she knows that her husband wanted a boy. Today, the trend is to want one child of each sex. Because of the availability in America of better forms of contraception and economic factors such as the expense of raising children, most couples are having fewer children today compared with the 1950s. The importance and stress of producing the “right-sex” infant is evident. Being the “wrong sex” can, combined with other factors, place an infant at risk of child abuse. The parents may find fault with and place blame on the infant for not meeting this expectation (Hax, 2015).

Health intervention focuses on the identification of high-risk families and the promotion of positive relationships between infants and parents. The nurse promotes the good health, appearance, and developmental potential of the infant. Increasing the parents' feelings

of adequacy and self-esteem will promote their acceptance and care of the infant. Most importantly, follow-up care for these families is a high priority to ensure that adequate support and help are available.

Race

Race refers to the classification of human beings into groups based on particular physical characteristics, such as skin pigmentation, head form, and stature, attributable to a common inheritance. A range of physical variation exists among people of different races with regard to growth rate, dentition, body structure, blood groups, and susceptibility to certain diseases, as well as a great many other variables.

In assessing an infant, the nurse not only collects data but also compares the data with established norms, such as a standardized growth chart. When the norms chosen are not appropriate for the individual (e.g., an Asian infant's growth is assessed on the basis of norms for white children), the assessment will not be accurate. The nurse who works with families from a variety of racial groups has an understanding of each background and how it relates to health and health care. To facilitate nursing care for a family from a racial group different from that of the health care provider, effective communication must be established. This communication will help foster an understanding of the other's point of view and frame of reference. Each family member is viewed as an individual, as well as a family unit. There is no stereotyping of families within a racial or ethnic group. Despite common language, color, or historical background, not all members of a particular racial group are alike. This diversity presents, without doubt, considerable challenges for nurses who work with families with infants (Simon et al., 2015). Universal norms by which to measure one's growth and skill capacity do not exist. The nurse recognizes the differences and intervenes appropriately. The orientation of health maintenance and disease prevention is basic to good health practices, regardless of racial makeup. This concept is the main focus of all health care. (See Chapter 2 for further details.)

Genetics

In the past several decades, remarkable progress has been made in our understanding of the structure and function of genes and chromosomes. These advances have been aided by the complete sequencing of human DNA—our genome. This knowledge can now be applied to medical care. The desired and expected outcome of any pregnancy is the birth of a healthy, perfect baby. Parents experience disappointment when they discover that their baby has been born with a defect. A **birth defect** is an abnormality of structure, function, or metabolism as a result of a genetic or environmental influence on the fetus, often a combination of both. Couples may refrain from having another child because they have had one with a serious birth defect and do not want to risk another. In these situations, genetic counseling provides information that is needed to understand a hereditary disorder and its associated risks. The main goal of counseling is to explain birth defects to affected families and to allow prospective parents to make informed decisions about childbearing.

Using the basic laws governing heredity and knowing the frequency of specific birth defects in the population, the genetic counselor can often predict the probability of recurrence of a given abnormality in the same family. An important aspect of primary prevention is identifying families at increased risk and referring them for counseling (Nussbaum et al., 2016). The aspects to be reviewed in the initial interview include the following:

- *Maternal age.* The risk of having a child with Down syndrome increases significantly for the woman older than 35 years. In Down syndrome, there are three chromosomes in the 21 chromosome group (trisomy 21). Characteristic features of Down syndrome include upward-slanting eyes; small, malformed ears; large, protruding tongue; broad hands and feet; and some degree of mental disability.
- *Ethnic background.* Several genetic disorders occur with higher frequency in certain groups. Anyone can be a carrier of Tay-Sachs disease, but the disease is most common among the Ashkenazi Jewish population. The incidence of Tay-Sachs disease in this

population is 1 in 3600 people. The carrier frequency for Tay-Sachs disease is 1 in 27 (National Tay-Sachs & Allied Diseases Association, 2015). Abnormal deposits of lipids (fats) in the cells of the cerebral cortex, spleen, liver, and lymph nodes are characteristic of **Tay-Sachs disease**. Rapid and progressive deterioration of the brain and nervous system ensues, with death typically occurring by age 6 years. An autosomal recessive gene transmits the disease. Blacks have a much greater chance of carrying the sickle cell trait than does the general population. **Sickle cell anemia** is an autosomal recessive condition that occurs in 1 in 365 black births and causes severe hemolytic anemia crises. Approximately 100,000 Americans have sickle cell disease, which is a lifelong illness. One in 13 black Americans carries the sickle cell trait (National Institutes of Health, 2015).

- *Family history.* Certain diseases, such as Huntington chorea, hemophilia, and mental retardation, are often hereditary. Huntington chorea (an autosomal dominant disease involving the brain) is characterized by deterioration of intellectual functions and involuntary movements of the limbs, face, and trunk. Once symptoms have manifested themselves, a steady deterioration leads to death in approximately 20 years. Hemophilia is a sex-linked recessive coagulation disorder caused by a functional deficiency of a clotting factor; it leads to prolonged bleeding. Hemophilia passes from an unaffected carrier mother to her male offspring. It affects 1 in 5000 male births. Approximately 400 babies are born with hemophilia each year in the United States, with approximately 20,000 people with it in the United States presently (Zaiden et al., 2015).
- *Reproductive history.* Spontaneous abortions, stillbirths, and previous live-born children with birth defects or slow development may indicate an increased risk.
- *Maternal disease.* Several maternal disorders are associated with a higher frequency of birth defects, including diabetes mellitus, seizure disorder, mental disability, and phenylketonuria. Prenatal diagnosis offers the couple the option of aborting a fetus that has certain genetic disorders. For many people, however, this option is

unacceptable. Chapter 16 discusses the various tests used for prenatal diagnosis.

The nurse's role throughout the genetic counseling process is to provide the vital link between the counseling team and the high-risk couple. Nurses need to understand not only the foundations of genetics and genomics but also the implications of these sciences for those for whom they provide care. The nurse is involved in case finding, referral, and family education. As a result of the new and expanding technology devoted to genetic and genomic research, a growing number of genetic tests are available for the screening, diagnosis, and treatment of rare and common diseases. All nurses will need to become knowledgeable about the basics of genetics and genomics and their applications to clinical care so that they can provide quality health care that is appropriate to their setting, population, geographical location, access, and coverage. This knowledge will allow nurses to provide appropriate information to care recipients regarding genetic tests that are part of their own health care (Lopes et al., 2015).

Gordon's Functional Health Patterns

Health Perception–Health Management Pattern

Health promotion is aimed at assisting the infant and the infant's family to change behavior to produce better physical and emotional health in adulthood. The old saying "an ounce of prevention is worth a pound of cure" has great merit, and if considered, and acted on, this can be very effective in promoting an individual's health. To reach this goal, the nurse encourages childrearing practices that promote normal growth and development, fosters attitudes and values compatible with health, and teaches appropriate use of health services. Health-promotion measures, by nurses, aim to prevent and minimize ill health of all women and their families. Nurses provide a pathway to access health care, engaging them to stay healthy, and share in decision-making concerning their own health, and help families that need to negotiate the health care system (Arnold & Boggs, 2016). The nurse promotes the infant's health through the parents, who determine the care practices for the dependent infant.

Health is largely a subjective judgment. Each person's perception of health is related to physical and mental capabilities, self-concept, relationships with others and the environment, and personal goals and values (Sanders, 2015). With this understanding, the nurse uses every opportunity to convey confidence in the parents' health perception–health management pattern and to improve their ability to implement behaviors that promote the infant's health. When parents learn and adopt behaviors that improve their own health, they are more likely to ensure that the health needs of their infant are met. Parental modeling increases the chances that good health practices will be retained throughout the child's life.

The goals of nursing practice with infants and their families are to promote individual motivation for health, to assist the family to identify health needs, and to develop problem-solving skills within the family unit using the family's own resources. To meet these goals, the nurse identifies the family's perception of good or bad health

practices, which greatly influences participation in health-promoting activities. Age, gender, educational level, cultural orientation, financial status, and occupation combine to influence health perception. When parents believe that the infant is more susceptible to a health problem if promotional behavior is not enacted, they become more motivated to adopt the behavior.

The nurse's task helps the parents recognize their infant's susceptibility and the potential consequences when healthy practices are not instituted. The nurse works within the family's health perception framework to become acquainted with the characteristics that influence the infant's health. Unless caregivers meet their own personal needs, they will be unable to meet their infant's developmental needs. The empowerment and growth of mothers is a key element to facilitate the successful development of their infants. Women with higher levels of education have healthier children (US Agency for International Development, 2017). The nurse supports the parents, strengthening their parental confidence and self-esteem, providing information on meeting their infant's needs, and reinforcing their health perception–health management pattern.

Nutritional-Metabolic Pattern

One of the most important aspects of health promotion in the infant is nutritional status. Many opinions have been expressed about the infant's nutritional needs. As research in this area continues, recommendations and opinions will change; however, some basic facts about nutrition remain fairly consistent. During the infancy period, it is almost all about milk—breast or formula. Milk will provide practically every nutrient the infant needs for the first year of life. Infant nutritional requirements are based on what is considered necessary to support life, provide for growth, and maintain health.

Essential Nutrients

During infancy, a period of rapid growth, nutrient requirements per pound of body weight are proportionally higher than at any other

time in the life cycle. Water, proteins, fats, carbohydrates, vitamins, and minerals are the essential nutrients in any diet. Because the first year of life is a period of rapid growth, nutritional needs during this period are especially important and always changing. Water is vital to survival. A person can live for several weeks without food but can survive only a few days without water. Because the infant's body weight is approximately 75% water, the baby must consume large amounts of fluid to maintain water balance. Under normal circumstances the water requirements of healthy infants who are fed adequate amounts of breast milk or properly reconstituted infant formula are met by the breast milk or infant formula alone. Supplemental water is not necessary, even in hot, dry climates (US Department of Agriculture [USDA], 2015). The sources of water are fluids (primarily milk) and food; most strained foods are 75% to 85% water. Most infant diets, without supplementation, meet the basic water requirement.

The infant must also consume sufficient high-quality protein to facilitate growth and development. The recommended daily protein requirements are 9 g during the first 6 months and 11 g during the second 6 months. No more than 20% of an infant's daily energy requirement should come from protein because infants are not able to process and excrete the excess nitrogen from higher-protein diets (USDA, 2015).

Carbohydrates should supply 30% to 60% of the energy intake during infancy. Approximately 37% of the calories in human milk and 40% to 50% of the calories in commercial formulas are derived from lactose or other carbohydrates. The recommended daily intake of carbohydrates is 60 g for infants up to 6 months of age and 95 g for infants 7 to 12 months old (USDA, 2015).

For infants, 31 g of fats per day for the first 6 months of life and 30 g of fats per day during the second 6 months of life (approximately 40–50% of the calories) are recommended (USDA, 2015). These quantities are present in human milk and in all formulas prepared for infants. Breast milk and formulas provide approximately 50% of their calories as fat. Significantly lower intakes, such as in skim milk feedings, can

result in an inadequate energy intake.

Vitamins are essential nutrients in the infant's diet that regulate metabolism and allow more efficient use of carbohydrates, fats, and proteins within the body. Although most infants receive adequate vitamin intake through formula, breast milk, and food, recent research has raised a concern about a vitamin D deficiency in infants who receive only breast milk. Vitamin D deficiency is actually quite common among US infants. The Institute of Medicine (IOM) recently revised the recommended dietary allowances for vitamin D. According to the IOM, nutritional rickets is on the rise in the United States among children with certain risk factors: dark-skinned infants, infants that are breastfed for long periods without receiving any vitamin supplementation, and infants with decreased exposure to sunlight. The IOM (2015) recommends that this population needs vitamin D supplementation of 65 mcg/day from birth to 6 months and 80 mcg/day for the second 6 months of life.

Minerals are found in relatively small amounts in the infant's body but are vital elements in body structure and control of certain body functions. Mineral intake for infants appears to be adequate, except for iron and fluoride.

The full-term infant is born with stores of iron adequate to meet the needs for hemoglobin production for approximately 4 to 6 months. After this time, body stores may need to be replenished. Although iron in human milk is bioavailable, both breastfed and formula-fed infants should receive an additional source of iron by 6 months of age. Iron-fortified formula and cereals are the most commonly used food sources.

Fluoride, concentrated in the bones and teeth, helps reduce dental caries. Although fluoride is important for strong tooth development, it is not recommended during the first 6 months of life. Supplementation is necessary only when the diet contains insufficient fluoridated water.

A review of these requirements shows that milk (breast or formula) meets most of the infant's nutritional needs when consumed in adequate amounts, plus vitamin D supplementation for the high-risk

infants. No data support the theory that solid foods are needed to meet these nutritional needs, at least during the first 6 months of life.

If the mother chooses to formula-feed verses breastfeed her infant, the nurse should instruct the mother about safe preparation of infant formula as follows:

- Check the expiration date and condition of each container of formula.
- Wash the top of the container with soap and water before opening it.
- Wash hands thoroughly before preparing infant formula.
- Prepare the bottle by washing it with soap and water or in the dishwasher.
- Follow the manufacturer's instructions for how much water to use.
- Warm the formula by placing it in warm water, never in a microwave oven.
- Shake the bottle well and feed the formula to the infant.
- Store the leftover formula safely in the refrigerator and discard it after 48 hours.

Food Additives

In addition to their questionable nutritional value, additives in commercial baby food can negatively influence an infant's health status. The purposes of food additives differ, including adding nutritional value; preserving or extending shelf life; facilitating preparation; improving flavor, color, and texture; and keeping flavors and textures consistent (WHO, 2015a).

Commercially prepared baby foods are generally safe, nutritious, and high quality. In response to consumer demand, baby food manufacturers have removed much of the added salt and sugar that their products once contained and have eliminated most food additives.

Nutrition problems include undernutrition, in which infants do not receive an adequate supply of an essential nutrient, and overnutrition, in which they receive more of a certain nutrient than is needed for

healthy growth and development (Fildes et al., 2015). For infants in the United States, both of these problems are present. A parent who wants the infant to have family foods rather than commercial baby food can blenderize a small portion of the table food at each meal. This choice necessitates cooking without salt or sugar, which is the practice of baby food manufacturers. Making baby food is easy and economical. Written resources are available for parents who are interested in more details about home food preparation for infants.

Parents should be encouraged to read baby food labels carefully. Nurses can obtain lists of baby foods and their ingredients from the manufacturers. The best overall recommendation that nurses make to parents is to provide their infants with a well-balanced diet and avoid excesses.

Breastfeeding

An infant's first and preferred source of nutrition should be breast milk. Ongoing evidence-based practice findings strongly indicate that the lifelong health from breastfeeding that is bestowed on the infant also greatly contributes to the health status of the mother, the family, and society at large (Busch et al., 2015). Research throughout the years has demonstrated unequivocally that exclusive breastfeeding is the preferred method of infant feeding for the first 6 months of life and should be continued for at least the first year of life and beyond for as long as mutually desired by the mother and child (AAP, 2015b). Breast milk is often called the perfect food for the infant and for the mother, because of its composition and because it does not have to be purchased, cooked, or stored. Both the American Dietetic Association and the AAP have released position statements in support of breastfeeding. This has influenced a number of health-promotion strategies in the United States. In *Healthy People 2020,* objectives MICH 21 through MICH 24 address breastfeeding. In all objectives the target is to increase these activities by 10% by 2020 (US Department of Health and Human Services [USDHHS], 2010) (Box 17-2: Research for Evidence-Based Practice). The United States breastfeeding initiation rates have risen slowly since the grassroots movement began years

ago. The number of mothers still breastfeeding at 6 months is up to 49% and those at 12 months is up to 27% (Lauwers & Swisher, 2016). If the nation is to meet the Surgeon General's goal by the year 2020, efforts to promote breastfeeding must be strengthened in hospitals, health maintenance organizations, private health care offices, and public health clinics. The Affordable Care Act passed in 2010 contains several elements of lactation support. It requires employers to provide a private place for breastfeeding employees to express milk during the work day and also requires health insurance coverage for breastfeeding support, counseling, and equipment (US Congress, 2010).

Box 17-2

Research for Evidence-Based Practice

Trends of US Hospitals Distributing Infant Formula Packs to Breastfeeding Mothers, 2007 to 2013

Objective: Distribution of infant formula samples to new mothers before hospital discharge has been a practice on maternity units since the early 20th century. Although appearing to be innocuous, this practice is viewed as a marketing tactic that adversely affects breastfeeding duration and exclusivity. The purpose of this study was to evaluate trends in the incidence of hospitals and birthing centers still distributing infant formula discharge packs to breastfeeding mothers on their being discharged home in the United States from 2007 to 2013.

Methods: Every 2 years a survey is administered to all hospitals with registered maternity beds in the United States. A Web-based or-paper-based questionnaire was distributed and completed by the person most knowledgeable about breastfeeding-related practices within that facility. The researchers examined the distribution of infant formula discharge packs to breastfeeding mothers from 2007

to 2013 by state and hospital characteristics.

Results: The percentage of hospitals and birthing centers distributing infant formula discharge packs to breastfeeding mothers was approximately 72% in 2007 and 32% in 2013, a decrease of 41% in 6 years. In 2007 there was only one state (Rhode Island) in which less than one-quarter of the hospitals distributed infant formula discharge packs to breastfeeding mothers. By 2013, there were 24 such states with less than 25% distribution. Distribution declined across all hospital characteristics evaluated irrespective of whether they were teaching hospitals or nonteaching hospitals and irrespective of hospital size.

Conclusions: The distribution of infant formula discharge packs to breastfeeding mothers was reduced substantially from 2007 to 2013.

Nursing implications: From results of this study, hospitals are starting to implement optimal, evidence-based maternity care to support mothers who desire to breastfeed by not providing infant formula discharge packs. This trend allows nurses to encourage and support mothers to exclusively breastfeed for the first 6 months of their infant's life and continue to breastfeed for the first year and beyond if they so desire without a "tease" pack available. Nurses play a vital role in preparing, educating, encouraging, and supporting women to breastfeed and are instrumental in facilitating initiation and continuation of breastfeeding.

Modified from Nelson, J. M., Li, R., & Perrine, C. G. (2015). Trends of US hospitals distributing infant formula packs to breastfeeding mothers, 2007 to 2013. *Pediatrics, 135*(6), 1051–1056.

WHO, the United Nations Children's Fund (UNICEF), and *Healthy People 2020* have adopted the Baby-Friendly Hospital Initiative in an attempt to establish a global effort to increase breastfeeding (WHO, 2015c). To become a baby-friendly health care facility, the 10 steps to successful breastfeeding must be implemented, as shown in Box 17-3.

Box 17-3

Baby-Friendly Hospital Initiative Breastfeeding Guidelines

- Have a written breastfeeding policy that is communicated routinely to all health care staff.
- Train all health care staff in the skills necessary to implement this policy.
- Inform all pregnant women about the benefits and management of breastfeeding.
- Help the mother initiate breastfeeding within 30 minutes after birth.
- Show mothers how to breastfeed and how to maintain lactation even when they are separated from their infants.
- Give newborn infants no food or drink other than breast milk unless medically indicated.
- Practice rooming-in; allow mothers and infants to remain together 24 hours a day.
- Encourage breastfeeding on demand.
- Do not give pacifiers to breastfeeding infants.
- Foster the establishment of breastfeeding support groups and refer mothers to these groups when they are discharged from the hospital or clinic.

From Baby-Friendly USA. (2016). The guidelines & evaluation criteria. https://www.babyfriendlyusa.org/get-started/the-guidelines-evaluation-criteria.

Women's decisions of whether to breastfeed are influenced by

information they receive from their health care providers. The decision to breastfeed is complex and depends on multiple factors—demographic, biological, psychological, social, and educational. Guidance given to mothers on breastfeeding in the postpartum period increases their knowledge of the subject and, consequently, the prevalence of this practice for a longer period. Nurses need to provide mothers with guidance and congruent, sensitive, effective, and beneficial support for them to be successful with the breastfeeding experience (Santos et al., 2015). Low levels of actual or perceived professional support and lack of knowledge, support, and measures needed to cope with breastfeeding difficulties are found to be associated with formula-use decisions. Data suggest inconsistencies between health care provider's perceived support and behaviors, lack of knowledge, and significant lack of skill in the assessment and management of breastfeeding mothers (Radzyminski & Callister, 2015). Because of the important role in the mother's choice of infant feeding, nurses can be instrumental in working toward the national goal to increase breastfeeding by educating all women about the advantages of the practice (Box 17-4). Community nurses who are caring for breastfeeding mothers stress the following tips to increase the duration of this activity:

Box 17-4

Advantages of Breastfeeding

Breast Milk

- Has the correct balance of all essential nutrients for infants
- Is full of immunological agents to protect against disease
- Is easier to digest than is formula
- Contains antiinflammatory properties

- Promotes growth of *Lactobacillus bifidus*
- Reduces risk of childhood obesity, ear infections, and diabetes
- Reduces risk of asthma and respiratory viruses

Breastfeeding

- Is cheaper and more convenient than formula
- Provides a unique bonding experience for both the infant and the mother
- Assists in the process of uterine involution for the mother
- Decreases postpartum vaginal bleeding
- Reduces childhood obesity
- Strengthens the immune system of infants
- Incidence of pneumonia, colds, and viruses is reduced
- Oxytocin is released, which promotes better healing in the postpartum period
- Protects infants against developing allergies
- Decreases costs for public health programs (e.g., WIC)
- Decreases SIDS rate, overweight, and obesity in adulthood
- Decreases environmental burden for disposal of formula cans and bottles
- Promotes weight reduction for new mother

From Lauwers, J., & Swisher, A. (2016). *Counseling the nursing mother: A lactation consultant's*

guide (6th ed.). Burlington, MA: Jones & Bartlett Learning; Mercola, J. (2016). The amazing benefits of breastfeeding. http://articles.mercola.com/sites/articles/archive/2016/01/02/amazing-benefits-breastfeeding.aspx.

- Drink 1 quart of fluids daily to produce a sufficient quantity of breast milk.
- Watch the infant, not the clock. Look for early signs of wanting-to-feed behaviors.
- Sunlight is the principle source of vitamin D, so a supplement might be needed.
- Try to rest when the infant sleeps, so you do not become overtired.
- Consume 300 to 400 kcal/day above the prepregnancy energy intake to avoid excessive weight loss.
- Learn the appropriate interventions for engorged breasts, sore nipples, plugged ducts, infection, and leaking nipples.
- Expose nipples to air after each feeding and allow some breast milk to dry on nipples for their lubricating and antiinfective properties.
- Learn about the use of breast pumps and milk storage.
- Join breastfeeding support groups for continued help within the community.
- Learn about the effects of drugs, environmental pollutants, alcohol, and nicotine on breast milk.
- Breastfeeding is more than just supplying nutrients for growth—it contributes to an intimate and special relationship between you and your infant (Lauwers & Swisher, 2016)

Introduction of Solid Foods

The timing of the first introduction of solid food during infancy may have potential effects on lifelong health. No scientific evidence is available on the best time to introduce solid foods during infancy. At approximately 4 to 6 months of age, the infant is usually physiologically and developmentally ready to have solid foods, either commercial or home-prepared. The infant should be able to do the

following developmental tasks before solid foods are introduced: sit with support, have good head and neck control, push up with straight elbows from a lying face-down position, lean forward and open mouth when interested in food, and turn away when not hungry. The AAP and WHO recommend that waiting until the child is 6 months old to introduce solid food decreases the tendency for the child to develop food allergies and reduces the risk of childhood obesity. The introduction of various foods was recommended to supply a more appealing, diversified diet for the infant; supply energy, iron, and vitamins; and provide needed trace elements (Duryea & Fleischer, 2015). The decision to start solid foods at 4 to 6 months of age is based more on neuromuscular and developmental readiness of the infant than on any hard scientific data, but research does validate the lowered risk of developing food allergies if solid foods are not introduced until 6 months of age. It is now thought that early introduction of highly allergenic foods, such as eggs, peanuts, tree nuts, and fish, can actually decrease the risk of allergy (Duryea & Fleisher, 2015).

All infants develop according to their own schedules, and some are ready to start eating solid foods earlier than other infants. The addition of foods should be governed by an infant's nutritional needs and readiness to handle different forms of foods (Brown & Rowan, 2016). The order of food introduction and the specific amounts to be given are based on tradition rather than on scientific fact. No scientific studies have been performed to determine whether a specific order of infant food introduction is necessary or the amounts needed for optimal development. The sequence of solids typically recommended by the AAP is cereal, fruits, vegetables, and meats. Certain foods to avoid for any infant younger than 12 months include whole cow's milk; foods that could cause choking—nuts, grapes, raw carrots, or candy; and honey. Cow's milk is not recommended because it does not contain adequate iron; honey is not recommended because of the potential risk of exposure to a harmful bacteria toxin—botulism poisoning. The typical sequence in which foods are introduced is shown in Box 17-5. A few tips to assist parents in making the

introduction of solid foods a smooth transition are listed in Box 17-6. Recommendations for food introduction by age and sequence are given in Table 17-5.

Box 17-5

Solid Food Introduction Sequence

- Cereals, particularly rice because of nonallergenic property
- Fruits such as peaches, pears, and applesauce
- Vegetables, with yellow vegetables (squash and carrots) given before green vegetables (peas or beans)
- Strained meats, such as nonallergenic lamb or veal

From Duryea, T. K., & Fleischer, D. M. (2015). Patient education: Starting solid foods during infancy (beyond the basics). *UpToDate*. http://www.uptodate.com/contents/starting-solid-foods-during-infancy-beyond-the-basics.

Box 17-6

Tips for Introducing Solid Foods

Assess the Infant's Readiness to Consume Solid Foods First

- The infant can sit up (with support) and can hold her/his head and neck up well.
- The infant's birth weight has doubled.
- The infant is interested in what you are eating and may even try to grab food from your plate.
- The infant can keep food in her/his mouth rather than letting it

dribble out.

- The infant shows signs of being hungry by wanting to nurse more often.

If readiness is validated, then begin with the following:

- The infant's first solid foods should be smooth and runny. Gradually, the infant will be ready to accept a slightly rougher texture.
- Puréed foods are used until the infant has teeth; chopped foods are used when the infant can chew.
- Introduce only one new food at a time and in small amounts for 5 to 7 days. When the new food is not tolerated or the infant is allergic to it, the new food can be identified quickly and discontinued.
- The infant must learn how to handle solid foods. Because infants use sucking movements, part of the food is ejected from the mouth. With time and practice, the infant learns how to take solid food from a spoon.
- Do not mix solid foods together; the infant should learn to appreciate different tastes and textures.
- Always feed the infant with the infant in an upright position; do not feed the infant solids from the bottle.
- Until the infant is 1 year old, feed the infant milk before solid foods.
- Look at, smile at, and talk to the infant during feeding.
- Do not give honey to infants younger than 12 months because of the risk of infant botulism.
- Respect the infant's likes and dislikes; rejected foods may be

reintroduced later.

- Avoid peanuts and peanut butter because of the potential for severe allergic reactions.

From US Department of Agriculture. (2016). Infant feeding guide. https://wicworks.fns.usda.gov/infants/infant-feeding-guide.

TABLE 17-5

First Foods for the Infant

Age (Months)	Addition
4–6	Iron-fortified rice cereal, followed by other cereals
5–7	Strained vegetables and fruits and their juices
6–8	Protein foods (cheese, meat, fish, chicken, and yogurt)
9	Finely chopped meat, toast, teething crackers
10–12	Whole egg, whole milk (allergies less likely now)

From Duryea, T. K., & Fleischer, D. M. (2015). Patient education: Starting solid foods during infancy (beyond the basics). *UpToDate*. http://www.uptodate.com/contents/starting-solid-foods-during-infancy-beyond-the-basics; La Leche League. (2016). First foods for baby. http://www.llli.org/faq/firstfoods.html.

Weaning

Weaning is a gradual, caring process that introduces the infant to a cup, which replaces the bottle or breast. The biological norm and desired method for weaning is to allow the infant to self-wean. Weaning should be started when the infant is ready. Developmentally, the infant can usually learn to use a cup by age 5 to 6 months; however, many children continue to nurse after they start using a cup. The infantile extrusion reflex needs to be absent. This reflex is present in very young infants and involves the tongue pushing out any material in the mouth not associated with sucking. The safety advantages of this are obvious, but weaning cannot be commenced until the infant has matured sufficiently for the reflex to be absent. In addition, weaning should not be started until the infant can sit only slightly supported and turn away his/her head to indicate

food refusal. The AAP recommends breastfeeding for at least the first year of life. WHO and UNICEF suggest that the health benefits of breast milk are important throughout the second and third years of life and that breastfeeding should be continued. However, because breast milk is very low in iron content, there has been concern about the possible impact of this advice on the development of anemia, a condition that if left untreated could cause irreversible developmental delays. The iron in human milk is absorbed more efficiency (60%) than the iron in cow's milk (4%), partly because of the high amount of vitamin C in human milk (Lauwers & Swisher, 2016). Weaning should be started at this age by the infant periodically being offered sips of water or juice. Initially the infant may not be eager to accept these offers but should become accustomed to this new experience fairly quickly (Box 17-7: Quality and Safety Scenario).

Box 17-7

Quality and Safety Scenario

How to Hold Your Infant for Feedings

- Sit or lie down comfortably with your back supported.
- Make sure the infant has one arm on either side of your breast as you pull him/her close.
- Use firm pillows or folded blankets under the infant as a means of support during the feeding. As the infant gets older, the extra support will likely be unnecessary.
- Support the infant's back and shoulders firmly.
- Do not push on the back of the infant's head.
- Correct positioning enables good attachment.

- The infant should be at a 90-degree angle, with his/her nose meeting your nipple.
- After the infant's mouth is open wide, pull him/her quickly to your breast.

Three Common Breastfeeding Positions

Football

- Hold the infant's back and shoulders in the palm of your hand.
- Tuck the infant up under your arm, keeping the infant's ear, shoulder, and hip in a straight line.
- Support the breast. After the infant's mouth is open wide, pull him/her quickly to you.
- Continue to hold your breast until the baby feeds easily.

Lying Down

- Lie on your side with a pillow at your back and lay the infant such that you are facing each other.
- To begin, prop yourself up on your elbow and support your breast with that hand.
- Pull the infant close to you, lining up his/her mouth with your nipple.
- After the infant is feeding well, lie back down. Hold your breast with the opposite hand.
- Cradle the infant in the arm closest to the breast with his/her head in the crook of your arm.

- Have the infant's body facing you, tummy to tummy.
- Use your opposite hand to support the breast.

Across the Lap

- Lay your infant on firm pillows across your lap.
- Turn the infant, facing you.
- Reach across your lap to support the infant's back and shoulders with the palm of your hand.
- Support your breast from underneath to guide it into his/her mouth.

Breastfeeding Is Going Well When…

- Your infant is feeding approximately eight times in 24 hours for 30 to 40 minutes at each feeding. Some infants need to eat more frequently until they learn to breastfeed efficiently. Other infants gain weight although they feed less often.
- At least one breast softens well at each feeding.
- You feel a tug, but not pain, when he/she sucks.
- The infant's arms and shoulders are relaxed during the feeding.
- The infant has bursts of 10 or more sucks and swallows at the beginning of each feeding.
- As your breast softens, the infant slows down to two to three sucks and swallows at a time.
- Your infant is content when you finish breastfeeding.
- By the time the infant is 4 days old, you should see at least six wet

diapers and two bowel movements every 24 hours.

- Signs that a good attachment has been made are:
- The infant's nose is free from the breast.
- The infant's chin is firmly pressed against the breast.
- The infant has round cheeks.
- If any areola is visible, it should be more above the top lip versus the bottom lip.

From Lauwers, J., & Swisher, A. (2016). *Counseling the nursing mother: A lactation consultant's guide* (6th ed.). Burlington, MA: Jones & Bartlett Learning.

Some infants accept the cup readily; other infants are extremely reluctant to give up the bottle, especially the bedtime bottle. Allowing infants to sleep with propped bottles can lead to aspiration if the milk flows too rapidly or the infant becomes too sleepy to coordinate sucking and swallowing. Another potential problem is baby-bottle tooth decay, of all upper teeth and some of the lower posterior teeth, from direct contact with sugar, syrup, honey-sweetened water, or fruit juice. When the infant falls asleep and stops sucking on the bottle, the sugary solution pools around the infant's teeth and remains there for long periods. The carbohydrate in the solution is fermented into organic acids that demineralize the teeth until they decay. By not using the bottle as a pacifier, parents can prevent this condition.

Some additional tips for counseling parents are as follows:

- Keep a calm, relaxed attitude throughout the weaning process.
- Let the child lead the way; it could take days, weeks, or months.
- Anticipate the previous feeding times and offer a cup or snack instead.

- Do not force an infant to use a cup; it is more detrimental to wean an infant sooner than later.
- Introduce the cup for one feeding per day and progress until the breast or bottle is surrendered.
- Drop a feeding out every few days until the evening feeding is the last one left.
- Be sure the infant is getting enough nutrition from other sources.
- Put only purified tap water into the bottle, and give the infant juice and milk from a cup.
- Remember that infants enjoy the accomplishment of using a cup; it is one of their first steps toward independence.
- Make sure to make up the bonding time with your infant by holding and cuddling the infant throughout the day (Williamson & Beatty, 2015).

Anticipatory Guidance

The infant progresses from a diet of milk alone to a diet of milk and solid foods within a short period. Understanding the infant's nutritional needs and developmental capabilities, the nurse can guide the parents in meeting them and in the process, foster healthy family-infant relationships. The health-promotion activity used in meeting proper infant nutrition focuses on parent education and positive reinforcement of parenting abilities.

Elimination Pattern

The infant develops an elimination pattern by the second week of life, usually associated with the frequency and amount of feedings. Both breastfed and bottle-fed infants progress to a pattern of fewer stools per day after the first few months of life.

A breastfed infant's stools have a mushy golden-yellow color and seedy, even consistency, with a slightly sour but clean smell, dissimilar to stools passed later in life. A bottle-fed infant's stools are firm, pasty, and smellier and resemble those of an infant eating solid

food. The breastfed infant has many daily stools during the first and second months of life, progressing to one stool per day or even one stool every 4 to 5 days in the later months before solid foods are introduced. The bottle-fed infant has two to four stools per day during the first month, tapering to one a day or even fewer at the end of infancy (Polan & Taylor, 2015).

For the first year of life an infant cannot control the bowels. Bowel evacuation remains under involuntary, reflexive control until myelination of the spinal cord is complete, usually by 14 to 18 months of age (Kliegman et al., 2015). Nurses advise overanxious parents to delay toilet training until the infant is developmentally ready. The stress in American culture on daily bowel movements makes many mothers concerned about their infant's elimination patterns. The breastfed infant may go for several days without having a bowel movement, which is usually not a problem. When the infant's behavior and feeding and sleeping patterns are normal, no elimination problem exists. A breastfed infant rarely becomes constipated when consuming adequate amounts of breast milk. Usually the nurse only has to reassure the parents and discuss normal elimination patterns. Urination increases as fluid intake increases. An infant who voids 6 to 12 times a day during the first few months of life is usually healthy and well hydrated. Voiding is involuntary until sometime during the second year of life, when bladder sensation develops. Irregular patterns of voiding characterize the remaining period of infancy.

Anticipatory Guidance

Anticipatory guidance and health promotion concerning elimination patterns of the infant consist of parental teaching and reassurance, with special emphasis on good hygienic practices. Reassuring the parents about the infant's inability to control elimination is important so that their expectations are realistic.

Activity-Exercise Pattern

Physical activity and exercise contribute to development and coordination throughout the life span; infants receive their exercise through play. Initially infants engage in play with themselves with their hands or feet, by responding to various sounds, and by rolling and getting into various positions. By manipulating objects and achieving pleasurable sensations, infants learn about themselves and the objects in the environment.

Activity Through Play

Play is crucial for an infant's social, emotional, physical, and cognitive growth. Exploration is the heart of play, as it is how infants learn about their body and the world around them. Although the word *play* suggests physical activity, the infant's first play is actually an exercise of the senses. The infant's first toys are visual. Through play, infants learn to hone their senses, to exercise their physical abilities, and to relate to other people. Most of the infant's play is solitary and repetitious. As each discovery is made, self-confidence and pride in the achievement are reinforced (as is the skill) through repetition.

As the infant enters the second half of the first year and becomes mobile, the family should provide the infant with increasing opportunities for spontaneous play and exploration. A planned play period in a safe environment should be established. The infant should have unrestrictive clothing so that movement can be free and unhampered. The caregiver should not interfere directly with the play but should be attentive to the infant's needs.

An important nursing role is assisting parents to promote play, stressing the importance of providing opportunities that are appropriate for the infant's age. Buying expensive toys is unnecessary; common household items, such as pots, pans, lids, and spoons, provide excellent objects for play purposes.

Activity Through Stimulation

Parental stimulation of the infant is an important developmental technique; the infant needs stimulation to learn about the world. This

activity does not require expensive objects, but rather involves experiences in sight, sound, and touch that are free and can be provided by any parent (Figure 17-1). Examples of stimulating experiences for infants include the following:

FIGURE 17-1 The mother provides an infant with comfort by her closeness.

- Having lullabies sung to them
- Listening to tape recordings of a heartbeat
- Seeing colorful mobiles in the crib
- Being rocked in a rocking chair
- Having a familiar face smiling close by
- Having space to wander when developmentally ready
- Looking at themselves in mirrors
- Listening to music

Anticipatory Guidance

Knowledge of developmental landmarks allows the nurse to guide parents in proper play and stimulation for infants. Handing a 15-

month-old child a ball and placing the child in a fenced-in back yard to play is not enough. These activities must provide interpersonal contact, activity, and exercise. Activity and exercise through stimulation and play are extremely important for adequate and healthy development (Johnson et al., 2015).

Sleep-Rest Pattern

The amount of sleep that infants need is closely related to their rate of growth. Initially infants sleep approximately 80% of the time, as demanded by their rapid growth. As growth begins to slow toward the middle of the first year of life, less sleep is needed. The 12-month-old infant sleeps for only 12 of 24 hours, a pattern that remains essentially unchanged through the second year. Many new mothers think that there is a link between the amount of food fed to their infant and sleep duration. Recent studies indicate that infants who received more milk or solid feedings during the day were less likely to feed at night, but not less likely to wake (Brown & Harries, 2015). The findings have important implications for nurses who support new mothers with infant sleep and diet in the first year. Increasing infant calories during the day may reduce the likelihood of night feeding but will not reduce the need for mothers to attend to the infant in the night. To assist parents in understanding normal sleep and rest patterns, the nurse stresses that no set schedule exists (Table 17-6).

TABLE 17-6

GROWTH AND DEVELOPMENT
Normal Sleep Patterns for Infants

Age (Months)	Hours in 24-h Period
2–3	Low: 10
	Average: 16.5
	High: 23
3–4	Low: 8–10 nightly
	High: 11–12 nightly (2 or 3 naps daily)
6–12	11–12 nightly (2 or 3 naps daily)
12–18	8–12 nightly (1 or 2 naps daily)

From Baby Center. (2016). Establishing good sleep habits: Newborn to three

months. http://www.babycentre.co.uk/a7654/establishing-good-sleep-habits-newborn-to-three-months; Stevens, M. S. (2016). Normal sleep, sleep physiology, and sleep deprivation. *Medscape.* http://emedicine.medscape.com/article/1188226-overview.

Anticipatory Guidance

Infant sleep patterns are a common concern for new parents. Health-promotion activities can also help parents determine the individual needs of their infant. The nurse stresses that longer sleep patterns are signs of maturation and that sleep and rest are recognized as having a significant influence on the infant's growth and development. Sleep problems are highly prevalent in early childhood. Frequently, parents seek professional help when they suspect their child has a sleep problem. The nurse may offer the parents helpful comments for promoting infant sleep patterns, such as the following:

- Provide a quiet room for the infant that is separate from the parents' room.
- Learn behavioral clues that signal that the infant is going to sleep and is not interacting socially.
- Encourage caretakers that periodic, brief arousals at night are normal for infants.
- Encourage the establishment of a bedtime routine and a consistent sleep schedule.
- Learn to become sensitive to sleep cycles and rest periods that the infant is establishing and base care accordingly.
- Attempt to schedule feeding times during wakeful rather than drowsy periods.
- Learn that certain cycles are intrinsic to infants and that each infant is unique.
- Discuss normal development of infants' sleep and napping patterns.
- Review safe sleep practices (sleeping position, surface, environment).
- Perform rituals for the infant, such as rocking or reading a bedtime

story, to provide comfort and security and let the infant know the expected behavior (Mindell & Owens, 2015).

If parents express a sleep concern, the nurse assesses their reactions, considers their definition of the concern, assesses the sleep environment, and observes the infant's own unique sleep patterns. Only then can the nurse's health-promotion approach be individualized to assist the family in caring for the infant.

Sudden Infant Death Syndrome

Sudden infant death syndrome (SIDS) is defined as the sudden death of an infant younger than 1 year old during sleep that is unexpected and unexplained after a thorough postmortem examination including autopsy, a thorough history, and scene evaluation. SIDS is the only cause of death derived by exclusion of other causes. The incidence of SIDS has decreased more than 50% in the past 20 years, largely as a result of the Safe to Sleep campaign. One consequence of the Safe to Sleep campaign is a significant increase in occipital flattening. Infants who develop a flat spot should be placed with the head facing alternative directions each time they are put to bed. Supervised prone positioning when the infant is awake, avoiding excessive use of carriers, and upright positioning when the infant is awake are also recommended (Horne et al., 2015). Despite declines in prevalence during the past 2 decades, SIDS continues to be one of the leading causes of infant death in the postneonatal period. SIDS is a complex, multifactorial disorder, the cause of which is still not fully understood. Behavioral risk factors identified in epidemiological studies include prone and side sleeping positions, preterm birth and/or infant low birth weight, smoke exposure, soft bedding, bed sharing, not breastfeeding, and overheating. Risk-reducing measures include use of a firm crib mattress, breastfeeding, keeping vaccinations up to date, avoidance of overheating due to overbundling, avoidance of soft bedding and objects in the crib, encouragement of supervised “tummy time” when the infant is awake, and consideration of the use of a pacifier during sleep once breastfeeding is established (Adams et al., 2015) (Box 17-8). These

factors may also be associated with sleep disorders in infants, principally with bedtime problems, abnormal night awakenings, and arrhythmic sleep. Although SIDS affects infants from all social strata, lower socioeconomic status, younger maternal age, inadequate prenatal care, and lower maternal education level are consistently associated with SIDS. The incidence of SIDS has varied over time and among nations. SIDS still accounts for 3500 cases of infant death in the United States annually and is the third leading cause of death among infants beyond 1 month of age (CDC, 2015d). By definition, the cause of SIDS is not known.

Box 17-8

Safe to Sleep Public Education Campaign

The Safe to Sleep campaign aims to educate parents, caregivers, and health care providers about ways to reduce the risk of SIDS and other sleep-related causes of infant death.

Safe to Sleep is an expansion of the original Back to Sleep campaign, which started in 1994. Back to Sleep was named for its recommendation to place healthy babies on their backs to sleep, the most effective action that parents and caregivers can take to reduce the risk of SIDS. Since that campaign started, the percentage of infants placed on their backs to sleep has increased dramatically, and the overall SIDS rates have declined by more than 50%.

The expanded Safe to Sleep campaign builds on the success and reach of the Back to Sleep campaign. In addition to strategies for reducing the risk of SIDS, Safe to Sleep also describes actions that parents and caregivers can take to reduce the risk of other sleep-related causes of infant death, such as suffocation.

Safe to Sleep campaign collaborators include the Eunice Kennedy Shriver National Institute of Child Health and Human Development; the Maternal and Child Health Bureau of the Health Resources and Services Administration; the CDC, Division of Reproductive Health; the AAP; the American College of Obstetricians and Gynecologists; First Candle; and the Association of SIDS and Infant Mortality

Programs.

The safe sleep strategies outlined in Safe to Sleep materials and publications are based on recommendations defined by the AAP Task Force on SIDS. The Task Force on SIDS released expanded guidelines in October 2011. More information about these recommendations is available at the Eunice Kennedy Shriver National Institute of Child Health and Human Development website.

On the basis of the AAP Task Force on SIDS recommendations, parents and caregivers can make changes to their babies' sleep environment to make it safer and to reduce the risk of SIDS and other sleep-related causes of infant death.

Parents should be instructed to allow supervised tummy time when the infant is awake and should be cautioned about the amount of time their infant spends in a car seat. Delayed gross motor development can be prevented by reduction of the amount of time the infant spends in the supine position. Tummy time is the key intervention in preventing gross motor delays in infants. This prone position provides

infants with increased physical challenges and gives them a chance to begin developing head control by strengthening neck muscles. Nurses should educate the parents to introduce prone positioning in short periods several times a day. As infants get stronger, they will use arm muscles to lift themselves and aid them to reach for toys or other objects. This strengthening is essential in assisting them in rolling over, crawling, pulling themselves up to stand, and developing fine motor development, including coordination and sensory processing.

Objective MICH 1.8 from *Healthy People 2020* (USDHHS, 2010) is to reduce infant deaths from SIDS from 0.55 per 1000 live births to 0.50 per 1000 live births. Objective MICH 1.9 is to reduce infant deaths from SIDS and other causes (including SIDS, unknown causes, accidental suffocation, and strangulation in bed) from 0.93 per 1000 live births in 2006 to 0.84 per 1000 live births by 2020. Both objectives advocate a 10% reduction in infant deaths.

When an infant dies suddenly, unexpectedly, and for no apparent reason, a family crisis occurs. The parents are devastated and completely unprepared for the shock, reacting with intense guilt, blaming themselves and each other, and agonizing over the part they may have played in the infant's death. Because many unanswered questions remain, these feelings are universal. Parents think there is something they could have done to prevent the tragedy. In most cases, nothing could have been done. Too frequently, the first sign that something was wrong is death. The nurse is in an excellent position to help the family through this crisis. Dealing with the family's grief is very difficult. Many families find strength in their faith to help them through this difficult time. Other family members and close friends can assist the family in their grieving process. Many receive solace and support from talking to other parents who have lost an infant to SIDS. Several parent groups are available from local chapters of the SIDS Foundation; the nurse can refer them to their local chapter.

The nurse's main supportive role for families coping with SIDS is listening and offering compassionate guidance through the weeks and months that follow. The nurse encourages parents to talk about their infant. Too soon, family and friends expect the surviving family to

“get over it.” A parent, however, is never able to “get over it”; it is only put in perspective and not so near the surface. Nurses need to actively participate in helping parents through their grieving process and remember a standard time frame is not applicable (Andreotta et al., 2015).

Nursing assessment of the infant at risk of SIDS includes observing the infant for apneic episodes. Usually, however, nursing assessment occurs after death and consists of support and providing appropriate resources for the family. Nursing diagnoses for sudden infant death might include the following:

- Spiritual distress related to coping with death
- Ineffective family coping related to the loss of an infant
- Dysfunctional grieving related to the parents' inability to cope

Nurses also discuss with the family feelings about caring for future children. Life can appear out of control, and parents may believe that they cannot care for another infant. These feelings must be resolved before another pregnancy is contemplated. When dealing with the families of SIDS infants, nurses can feel uncomfortable and helpless. As health professionals, they might speak in terms of easing the pain or alleviating the guilt of these families, but many times simple nonverbal human contact is sufficient to express concern and understanding.

Cognitive-Perceptual Pattern

Cognition is the process by which an individual recognizes, accumulates, and organizes the knowledge of the environment, beginning with the perception or recognition of an event within that environment. Cognitive development is concurrent with biological, adaptive, and psychosocial achievement. The infant's biological and cognitive developmental patterns (Piaget's sensorimotor period) were discussed earlier in this chapter. The focus of this section is on the infant's sensory and language development and the importance of stimulation of both developmental areas. From birth, infants possess sensory capabilities; all sensory organs are well developed and

functioning. As the infant is cared for and handled, the special senses become organized neurologically into a pattern of behavior that will greatly influence subsequent development.

Vision

Sight is the least developed sense at birth. The infant's initial visual impressions are unfocused, bizarre, unfamiliar, and meaningless. The visual system of the newborn infant takes several months to develop. The infant's eyes are not very sensitive to light in the first month of life, so it is okay to leave a light on in the nursery—it will not affect the infant's ability to sleep. Because everything is new and only somewhat significant, visual stimuli must be moving, bright, or flashing to capture the infant's attention. To help stimulate the infant's vision, decorate their room with bright, cheerful colors and also hang a brightly colored mobile above the crib that has a variety of shapes and colors. The infant's eyes are well developed at birth, but the muscles that attach the eyes to their sockets are weak. This weakness may be stressful to parents because the infant's eyes do not appear to function simultaneously. Parents can be assured that most infants coordinate their eye movements by the age of 3 months; by 6 months this function is mature. Table 17-7 summarizes visual developmental milestones.

TABLE 17-7

GROWTH AND DEVELOPMENT
Visual Development During Infancy

Age (Months)	Behavior That Indicates Vision
1–3	Fixes gaze on object 12–24 inches away
	Takes interest in bright colors and faces
	Follows objects in field of vision
3–6	Begins to show interest in hands
	Follows in range of 90 degrees
	Recognizes familiar objects
	Able to see full color by now
6–9	Visual scanning becomes more integrated
	Capable of organized depth perception
	Begins to perceive distances accurately

	Both eyes should focus equally now
9–12	Able to look for concealed items
	Converges on objects in close proximity
	Peripheral vision is well developed
	Judges distance well
12–18	Eye-hand coordination develops
	Depth perception more refined
	Ability to identify forms and shapes

Hearing

After the amniotic fluid has drained from the middle ear several days after birth, the infant's hearing becomes acute. Hearing is one of the better-developed senses in the infant; the fetus can even hear in utero and responds to loud sounds (Figure 17-2). The newborn can distinguish sound frequencies and turns toward a voice or another sound. The infant may be familiar with the mother's voice early in life. Sounds gradually gain significance and meaning when they are associated with caregivers, food, and pleasure.

FIGURE 17-2 A 9-month-old infant enjoying his own image in a mirror. (From Hockenberry, M. J., & Wilson, D. [Eds.] [2013]. *Wong's essentials of pediatric nursing* [9th ed.]. St. Louis: Mosby.)

The ability to listen and discriminate among sounds is an important task during infancy. Caretakers should talk to their infants, sing nursery songs, and make faces so the infants develop language and social skills. The use of baby rattles and musical mobiles is also a good way to stimulate the infant's hearing. The closer the infant is to the sound, the more easily the sound can be discriminated. The groundwork for verbal ability begins to develop long before words appear, and many believe that infants whose mothers talk to them tend to speak earlier than infants who are not exposed to these sounds (Burnham et al., 2015). Table 17-8 summarizes the infant's auditory development.

TABLE 17-8

GROWTH AND DEVELOPMENT
Normal Development of Hearing

Age (Months)	Behavior That Indicates Hearing
1–3	Is startled by loud noises
	Stops activity when spoken to
3–6	Turns eyes and head toward sound
	Responds to mother's voice
	Imitates own noises: "ooh" and "ba-ba"
6–9	Responds to own name
	Looks toward sounds
	Recognizes familiar sounds
9–12	Points to familiar objects or people
	Imitates simple words and sounds
	Locates a sound in any direction
12–18	Follows simple spoken directions
	Distinguishes between sounds
	Spoken words are well on their way

Your baby's hearing and communicative development checklist. https://www.nidcd.nih.gov/health/your-babys-hearing-and-communicative-development-checklist.

Smell

The ability to smell is fully developed at birth. The infant has many receptors in the nose, but it lacks the cilia that line the inside of the adult's nose. As a result, the infant has a keen sense of smell because odors reach the receptor cells easily. Within 2 weeks after birth, an infant can differentiate the odor of the mother's milk from other sources of milk, an ability developed when the infant is held closely (Berk & Meyers, 2015). At this time the infant begins associating the parents with their body odors, a perception that is important for infant-parent bonding.

Taste

Taste buds in newborns can be found on the tonsils and the back of the throat, as well on the tongue. Infants use their sense of smell from the start and can localize odors by turning their heads in the direction of the odor. The sense of taste is present at birth, and salivation begins at approximately 3 months of age. The four primary sensations are sour, salty, sweet, and bitter. The taste buds for sweet tastes are more abundant during early life than they are in later life, which may account for the preference for sweets that is characteristic of infants and children. An infant's reaction to salty foods does not come until approximately 4 to 5 months of age.

Touch and Motion

Touch is by far the most developed of all of the infant's senses, as it is the main way in which infants learn about their environment and bond with other people. The skin is the sensory organ for touch. Tactile sensation is well developed at birth, particularly on the lips and tongue. Perceptions of motion and touch are perhaps the most important of all senses. Rocking and other motions are sensations of equilibrium picked up by the middle ear. Skin-to-skin touching should be performed regularly; evidence shows that touch helps relieve the unspent tensions that infants develop and accelerates neuromuscular development (Berk & Meyers, 2015). Infants respond

with pleasure to rocking and other motions and to tactile sensations of warmth, closeness, and cuddling.

Language Development

Language development, an important aspect of the infant's cognitive and perceptual pattern, is affected by development of the intellect, maturation of the central nervous system, development of the organs of speech, and exposure to human verbalization.

As in other areas of development, language acquisition follows a definite sequence. During the first 2 months, most of the infant's sounds are vowels and are made primarily in the front part of the mouth (Fogel, 2015). Crying is the major means of communication during this period. Cooing sounds are heard at approximately 2 to 3 months, usually in response to an adult's voice. By 6 months, babbling sounds are heard, and by 9 to 10 months, the infant forms two-syllable sounds. By 12 months, words such as “ma-ma,” “bye-bye,” and “da-da” are emerging. From 15 to 18 months, an expressive jargon with rhythmical intonations develops, but words are recognized only rarely. The infant uses jargon along with pointing to express wishes.

Anticipatory Guidance

The nurse's knowledge and understanding of an infant's cognitive and perceptual behavior facilitates interaction with infants and serves as a guide in parental counseling. The main focus centers on stimulation, because each of the infant's senses is receptive to environmental stimulation. This activity helps the infant learn from the environment. When an infant is exposed to appropriate sensory stimulation, greater curiosity, improved mental capabilities, accelerated neuromuscular growth, enhanced gastrointestinal functioning, quicker weight gain, more rapid language development, and pleasing mother-infant interactions are likely to occur (O'Connor, 2015).

Parents are the primary providers of pleasurable and stimulating experiences for the infant. The nurse assists them by offering suggestions about suitable stimuli for each sensory modality.

Self-Perception–Self-Concept Pattern

Self-perception has a pervasive influence on all aspects of life. Self-concept consists of a set of attitudes regarding what each person thinks, believes, and feels about the self. These attitudes form a personal self-belief that is an abstraction referred to as "me." Many researchers believe that the infant determines self-existence by first noting that actions such as crying or smiling have an effect on others, which depends on receiving feedback (Berk & Meyers, 2015). Studies confirm that infants can identify themselves and therefore form a self-concept. Infants at 4 months of age were found to be particularly fascinated with their images in mirrors and smiled more at themselves than they did at pictures of other infants (Fivush & Waters, 2015).

As the infant continues to grow and mature, many circumstances combine to influence self-concept. How others relate to the infant's body and the messages that the infant receives from the body lead to knowledge of a physical self. The ability to use the body to influence others can lead the psychological self to conclude that someone cares about the infant (Feldman, 2015).

The infant's development of body image is gradual. At birth the infant has diffuse feelings of hunger, pain, anger, and comfort, but no body image. Initially, the infant knows only the self and regards the external world as an extension of the self. Only when infants begin to experience the environment through sensory modalities are they able to distinguish their bodies from animate and inanimate objects.

Nursing Suggestions

The nurse plays a vital role in assisting parents to foster the development of a positive self-concept and a good body image in their infant. Socialization is unique and begins in infancy. Parenting skills and style have a strong influence on outcomes of integrated socialization as infants develop. The nurse first identifies personal self-concept and how it influences individuals (Reed, 2015). The nurse stresses that the way in which parents treat the infant influences the infant's self-concept. Basically, infants and young children incorporate

their parents' interactions with them (good or bad) into their own view of self. Parents must understand that their infant's self-concept is an important, continuing event. What the infant knows and later believes about the self will affect all interactions with others, and by influencing what the infant will later attempt, the self-concept may have broad effects on the development of new skills. The mental state or the idea of "me" is that part of the self that makes reference to itself. This mental state develops over the first 2 years of life and is a function of both brain maturation processes and socialization (Reed, 2015).

Roles-Relationships Pattern

What happens during the first few months of an infant's life matters a great deal because this period of life provides a blueprint for adult well-being and sets the foundation for what follows. Researchers have explored extensively the effect of early bonding between parents and their infants, emphasizing that this initial attraction sets the stage for the later development of love and affiliation. The bonding process has many other implications for the infant's future development as well (Polan & Taylor, 2015).

Attachment and Bonding

The attachment relationship is a vital bond between the infant and the caregiver that, when secure, facilitates physical and psychological well-being.

Various theories have attempted to explain the basis for attachment behavior. Freudian psychoanalytical theory emphasizes that the bond between the child and the mother develops as a result of the mother's fulfillment of the infant's innate desire to socialize and the physical requirements for survival. Social learning theory contributes the principles of reinforcement to the attachment process; as the mother meets the infant's needs, discomfort is reduced or removed. The infant associates the pleasurable feeling of being satisfied with the mother, who becomes a significant other in the infant's life. The bonding

process is the basis for the mother-infant relationship, which, in turn, forms the basis for the interdependence that is necessary for the infant's psychological and physical development. All infants are born with the building blocks that develop into attachment behaviors, and thus all infants have the ability to form an attachment relationship with their primary caregiver (Fivush & Waters, 2015).

Just as the infant's behavior influences attachment, it also continues to influence the evolving maternal-paternal-infant relationship as the infant develops. Studies have shown that if the process of attachment is encumbered, later problems are more likely to occur, such as child abuse, **poor growth**, formally termed *failure to thrive syndrome,* and behavior problems. Poor growth is a physical sign that an infant is receiving inadequate nutrition for optimal growth and development. Poor growth generally describes an infant whose current weight, or rate of weight gain, is significantly below that expected of similar infants of the same age and sex (Kliegman et al., 2015).

Many factors are present when a relationship is being established and maintained. Most people enter a relationship with unrealistic expectations. Parents are no exception—they are going to be wise, patient, and devoted, and they will nurture their infant. Because the parents' self-esteem is associated closely with their infant's interactions and accomplishments, when parents' self-esteem is low, disappointment, anger, and a disturbance in the relationship with their infant can occur. In some instances this disturbed parent-infant relationship is short-lived and nothing harmful develops. When a disturbed parent-infant relationship continues, however, the infant is at risk of abuse and behavior problems (Box 17-9: Innovative Practice).

Box 17-9

Innovative Practice

The Touchpoints Model

The birth of a baby is a life-changing event for a couple and family. Although most infants develop through predictable yet individual

patterns of development, parents, especially first-time parents, are usually unaware of these patterns or have difficulty assessing their infant's progress and problems. All of these processes can be stressful for the parents, the entire family, and the infant.

The Touchpoints Model Program at Children's Hospital in Boston, Massachusetts, delivers a training model for practitioners, emphasizing the building of supportive alliances between parents and professionals around key points in the development of young children. The model is an outgrowth of Brazelton's (2011) book *Touchpoints* and research at Children's Hospital in Boston. The Touchpoints model provides a form of outreach through which multidisciplinary practitioners can engage parents around important, predictable phases of their baby's development. The Touchpoints model stresses preventive health through development of relationships between parents and providers; acknowledges that developing and maintaining relationships is critical to appreciating cultural, religious, and societal family dynamics; and encourages the practitioner to focus on strengths in individuals and families. Touchpoints is not a stand-alone model; it is intended to be integrated into ongoing pediatric, early childhood, and family intervention programs.

Touchpoints has gone on-line. Parents and professionals can get advice and information from Brazelton, T. B. (2011). Brazelton Touchpoints Center. http://www.touchpoints.org; Lester, B. M., & Lester, J. D. (2010). *Nurturing children and families: Building on the legacy of T. Berry Brazelton*. Chichester: Wiley-Blackwell.

Becoming a father and a parent can be a transformational process for a person. When an infant enters a father's life, a new depth of feeling and emotion are awoken within the two of them. The process of bonding is also important for fathers. Fathers do have direct effects on their infants, but their effects also are often indirect, mediated or moderated by their relationship with the infant's mother. Fathers are looking for a psychologically satisfying place within their families (Linton, 2015). Recently, a process called **paternal engrossment** has been used to describe the behavior pattern of fathers when they interact with their infants. It describes the father's total absorption and preoccupation with the presence of their newborn.

Infant/child abuse has occurred throughout history, yet its prevalence is difficult to estimate, partly because, like an iceberg, it is mostly hidden. Infant/child abuse is an important cause of pediatric morbidity and death and is associated with major physical and mental health problems that can extend into adulthood. Infant and child abuse, as defined by the WHO, constitutes all forms of physical and/or emotional ill-treatment, sexual abuse, neglect or negligent treatment, or commercial or other exploitation resulting in actual or potential harm to the infant/child's health, survival, development, or dignity (WHO, 2015b). The family traditionally has been considered a safe place for its members, but many infants are at risk of maltreatment. Infant and child abuse has always been a part of human history. Acceptable behavior toward infants is largely a learned phenomenon; the art of parenting is not instinctively acquired, as many people believe. Abusing parents are seldom “monsters”; they are merely individuals ineffectively coping with the demands of parenthood, for which there is little or no preparation, as well as other life stressors.

The scope of child abuse is extensive: estimates indicate that more than 650,000 infants and children in the United States are victims of abuse annually, and more than 1500 children die of abuse or neglect. Infants from birth to 1 year of age are the most vulnerable to abuse and neglect (CDC, 2015e). Children younger than 3 years of age are the most frequent victims. Women are more frequent abusers than are men, because they are the primary caregivers. Men abuse more

severely and commit sexual abuse more frequently. Child abuse does not discriminate among children; it occurs in families of every race, creed, and socioeconomic class.

Child-abuse syndrome is a clinical condition in infants who have suffered serious active or passive abuse at the hands of their parents or other caregivers. Physical trauma is not the only facet, but it is the most overt indicator of a dysfunctional family unit and a disturbed parent-infant relationship (Fanetti et al., 2015).

Active manifestations of abuse include the following:

- Brain injuries, subdural hematomas, and skull fractures
- Soft-tissue injuries, such as bruises, lacerations, or burns
- Fractures of the long bones and ribs; multiple fractures in various stages of healing
- Sexual abuse manifested by genital tissue injury; sexually transmitted infections
- Bullying manifested by intentional, aggressive behaviors toward others

Passive manifestations of abuse include the following:

- Poor nutrition, failure to thrive, and severe malnutrition
- Poor physical condition: neglected safeguards against disease, poor skin condition, and lack of medical attention
- Emotional neglect: rejection, indifference, and deprivation of love
- Moral neglect: allowing the infant or child to remain in an immoral atmosphere
- Spiritual abuse: incorporating religion into abuse of a child (Boy Scouts of America, 2015)

Abusing parents often have common patterns of behavior. As children, their own parents may have abused them. In this way, child abuse is cycled from generation to generation. The development of the maternal role on which the infant depends for health, progress, and survival begins during the mother's early childhood. Unless she received love and proper mothering, she will have difficulty with a relationship that entails the complete dependency of another person.

She may find the relationship with her own infant to be unrewarding, threatening, and frustrating. Feelings of inadequacy and guilt in the mother and father roles compound the problems.

Abusing parents are often socially isolated and have few people to whom they can turn during times of crisis; they also cannot support one another emotionally. If parents grew up with harsh methods of discipline, they may be prone to violence with their own children. These parents may view the infant as the person who can provide the love, support, and nurturing that is lacking in their own lives. When the infant does not fulfill their expectations, the risk of abuse increases (Bauer, 2015).

The abused infant or child is frequently singled out as someone who is different. This infant may be chronically ill, may have been born prematurely, may be hyperactive, may have been the product of a difficult and complicated pregnancy, or may have an obvious anomaly. Early bonding disturbances (inadequacies in feeding, holding, and caring for the infant) are characteristic signals.

The long-term effects of child abuse are profound. The victims lack basic trust (a major task of infancy) and confidence and self-worth. These deficits follow the victims into adulthood and parenthood, and the vicious cycle continues. One of the discouraging findings is that infants and children who were abused frequently grow up to be abusing parents (Magana & Kaufhold, 2015).

Across the United States great interest has been generated in attempts to identify parents in the prenatal and perinatal periods who have significant potential for child abuse. Nurses play a critical role in recognizing infants who have been intentionally harmed, because they are often the first to begin taking a history of the infant. The role of the nurse may include identifying abused infants with suspicious injuries who present for care, reporting suspected abuse to the child protection agency for investigation, supporting families who are affected by infant abuse, coordinating with community agencies to provide immediate and long-term care to the victimized infant, providing court testimony when necessary, providing preventive care and anticipatory guidance in the health care setting, and advocating

policies that support and protect vulnerable infants (Christian et al., 2015). Nurses work collaboratively with community agencies to provide follow-up care for the infant in danger of continued abuse. Nurses take appropriate action if they suspect an infant is at risk. Some of the biggest challenges of child protection come from our own internal reluctance to act, but doing nothing is not an option. The following measures have been undertaken to help prevent child abuse:

- Predictive questionnaires to be given to parents on postpartum units
- Recognition of parents who have difficulty relating to their infants through body language clues or verbalizations
- Closer follow-up during the postpartum period by the public health nurse
- Crisis hotlines made available to parents in distress

Before focusing on nursing interventions, the nurse makes several observations to assist in identifying a high-risk infant by answering the following questions:

- Does the mother hold the infant close and establish eye contact?
- Does the mother speak negatively about the infant?
- Does the mother intensely dislike the duties of motherhood, such as diapering, feeding, and so on?
- Does the mother expect too much of the infant at a particular stage of development?
- Does the mother focus her attention on the infant rather than on her husband?
- Does the mother have a good support system available?
- Does the mother act overly concerned about the infant's sex?

Most communities are seeking ways in which child abuse can be prevented through educational efforts, improved agency coordination, and development of new collaborative efforts and services for parents and infants. Laws for reporting abuse have been enacted in every state. Reporting all cases of suspected abuse and neglect is mandatory. Everyone must assist in this endeavor to

prevent continued abuse. It takes a community effort to address the problem.

Sexuality-Reproductive Pattern

An infant's identity begins at birth, when the gendered child is identified and caretakers behave a certain way toward the infant because of its sex. The infant's sexuality gives direction to its physical, emotional, social, and intellectual responses throughout life. Infants have a great oral sensitivity, enjoy skin-to-skin contact, and explore their own bodies for pleasure during the first year of life. A healthy, accepting attitude by caretakers is important in an infant's evolving sexual development.

Coping-Stress Tolerance Pattern

The term *stress* implies intense reaction to an experience and changes in usual behavior. Stress is a normal phenomenon that occurs throughout the life span, as, for example, when an individual experiences a developmental or situational crisis.

Developmental Crisis

Developmental crises are turning points or periods of great change. Most stressors that an infant experiences are a necessary part of growth and development. For example, learning new skills creates stress. The infant who is unable to move forward while learning to crawl experiences stress. The infant expresses this stress by crying for help. Other stressors are more psychosocial in nature, such as being left with a babysitter or in an unfamiliar place.

Situational Crisis

Situational crises are not anticipated easily and do not occur necessarily as part of the normal growth and development process. One major situational crisis during infancy is separation from the significant other. The following three distinct phases are evident in the

reaction to separation (Coch et al., 2015):

- *Protest.* Infant cries loudly, screams for the mother, and refuses attention of the substitute caregiver.
- *Despair.* Infant stops crying and becomes less active, withdraws, and becomes apathetic.
- *Withdrawal.* Infant takes an interest in the surroundings but tends to ignore or reject the mother when she returns, because she failed to meet the infant's needs.

Initially, with no time framework and no understanding of waiting, the infant has little ability to cope with stress. As maturity and a sense of security provided by the caregiver increase, the infant begins to wait a short time to have its needs met without protest. An infant who experiences stress reacts by crying, the main tool of communication. The infant gradually learns to tolerate greater stress with time.

Nursing Interventions

Every family needs good information, concrete resources, and consistent support to thrive. Nursing interventions that assist the infant and the infant's family in stressful situations are listed in Box 17-10. By allaying anxiety in the infant's caregiver, the nurse facilitates coping behaviors in the infant. The stressful situation and the problem-solving activities can be turned into growth-producing experiences for the family, with coping capacities strengthened for the future.

Box 17-10

Nursing Interventions to Assist in Stressful Situations During Infancy

- Attempt to meet the infant's needs promptly.
- Allow favorite toy or item of security to be present during stressful experiences.

- Allow familiar caregiver to be present to calm the infant.
- Attempt to keep the number of strangers interacting with the infant to a minimum.
- Attempt to provide a warm and accepting environment for the infant.
- Allow freedom of expression (crying) to reduce tension in the infant.
- Identify the infant's established daily routine and try to follow through with it.
- Reinforce the infant's need for expression.
- Establish a trusting relationship with the infant.
- Provide opportunity for play so the infant can vent fears.
- Provide emotional support for the parents so they can, in turn, give support to their infant.
- Try the five "S" system to soothe a crying infant:

- Swaddling
- Side/stomach position
- Shushing sounds
- Swinging
- Sucking

From National Fatherhood Initiative. (2016). Preventing child abuse: The crying baby.

http://www.fatherhood.org/fatherhood/preventing-child-abuse-the-crying-baby.

Values-Beliefs Pattern

A value is a standard or principle that reflects a person's judgment on what is important in life. When people communicate, they send both the content message of the spoken words and the unspoken message of who they are and what they believe. Values are pervasive and important and give a focus to both individuals and groups within a particular culture. Because values are attitudes learned especially from significant others within the environment, the parents' values-beliefs pattern greatly influences the care and development of the infant.

Nursing Interventions

By understanding and respecting the parents' value system, the nurse works within their framework of values in the counseling situation. The nurse communicates personal values to the family. To work successfully within a different value system, the nurse incorporates the following attitudes concerning the values-beliefs pattern into the nursing process (Clark, 2014):

- Believe in the ultimate worth of the infant and the family, regardless of their behavior or situation.
- Grant families the freedom to make their own informed choices and to experience the responsibilities and consequences of their decisions.
- Use knowledge of the family's value system in specific ways to reward and reinforce positive health practices.
- Value the growth potential inherent in developmental and situational crisis situations.
- Recognize your own value system and its influence on your behavior.
- Work with families without applying your personal value system in judging their behavior.

- Broaden your value system by accepting lifestyles different from your own.

The nurse influences the behavior of the parents, who have the greatest influence on their infant's values-beliefs pattern. The nurse accomplishes this task by modeling (living congruently with professed values), acting as a consultant by sharing pertinent information with parents, and modifying his or her own values. Nurses can anticipate a family crisis of values and can help to promote positive coping and effective use of social supports (Harkness & DeMarco, 2015).

Modeling can be a potent influence on another individual's behavior. In the counseling situation, the family looks to the nurse for guidance and assistance in promoting healthy childrearing practices. The methods by which the nurse interacts with the infant, listens to the parents' concerns, and demonstrates respect for the family unit are influencing factors in changing behavior.

Second, the nurse acts as a consultant to influence values. Advice on childrearing practices is overwhelming to parents; everyone has opinions. The nurse listens before giving advice to determine whether parents will accept the advice and to allow parents to decide whether the advice can be useful. Repeated attempts to convert parents to the nurse's value system can make them defensive and resistant to the advice.

Third, by expressing values and attitudes, but remaining open to other approaches, the nurse influences the values-beliefs pattern. Parents can realize that they are free to change and are not bound to values that others outside their value system express (Gardner et al., 2016). Communication skills can more effectively promote the health of the infant and the family.

Environmental Processes

Physical Agents

This section discusses various factors within the environment that can affect the infant's health status. The entire realm of accident prevention and safety promotion is applicable here.

According to the CDC (2015f), unintentional injuries, including motor vehicle traffic crashes, falls, poisonings, suffocations, drownings, and fires/burns, are the leading cause of death for people aged 1 to 44 years and the fourth leading cause of death for people of all ages. Beyond the emotional damage that accompanies such tragedies, the American Public Health Association (2015) reports that unintentional injuries cost the United States more than $70 billion per year.

One of the overall goals for the Quality and Safety Education for Nurses (QSEN) project is to meet the challenge of preparing future nurses who will have the knowledge, skills, and attitudes necessary to continuously improve the quality and safety of the health care systems within which they work. One of their competencies promotes safety within the environment.

Some areas applicable to this competency of safety for infants would be the use of flame-retardant sleepwear, car seats, and crib mattresses, and knowledge of measures to promote crib safety and toy safety.

Sleepwear made for infants aged 9 months or younger can be flame resistant or non–flame resistant. Flame-resistant clothing is usually labeled as such, and is either a synthetic fiber or treated cotton. Parents should be advised to select flame-resistant sleepwear for their infant and to follow the laundry instructions carefully to maintain this properly. Sleepwear for infants older than 9 months is required to be either flame resistant or snug fitting. Snug-fitting clothing that conforms to the body has less opportunity to ignite when exposed to a flame than loose-fitting clothing. Smaller sizes are not required to be snug fitting, because a smaller infant is less likely to be mobile enough

to expose himself/herself to a fire hazard.

All new cribs are required to meet strict safety standards; however, if parents accept a secondhand crib, they need to be advised to check the following:

- The slats should be no farther than 2.375 inches apart. Wider slats could allow an infant's head to become trapped between them.
- There should be no decorations or projections that could snag an infant's clothes. Avoid cribs with decorative cutouts in the headboard or footboard.
- Some older cribs were painted with lead-based paint, which could poison an infant who mouths or chews the wood. If unsure, strip the old paint and repaint it with new lead-free enamel.
- No screws and bolts that hold the crib together should be missing, and all should be tight. Avoid cribs with drop side rails. If a drop side rail detaches or becomes loose, an infant may become trapped between the mattress and the railing.
- The crib mattress should be firm and should fit very snugly, with no room for the baby to become trapped between the mattress and the crib. Do not cover the mattress with plastic or a quilt, which can suffocate a baby.

Never put an infant to sleep on a waterbed, pillow, quilt, beanbag chair, or sofa. All these surfaces increase the chance that a baby could suffocate or get his/her head or another part of his/her body trapped in the furniture.

Do not put pillows or stuffed animals in an infant's crib, because they can cause suffocation. Crib quilt bumpers also pose a risk for suffocation and should not be used. When your infant learns to sit, lower the mattress so he/she cannot fall out of the crib. Remove mobiles, and make sure draperies and window blind cords are well out of his/her reach.

Anticipatory guidance to promote infant toy safety would include instructions for parents purchasing new toys to follow the age guidelines on the packaging. Infant toys should have no tiny parts that pose choking hazards, and nothing on the toy should be sharp or

detachable (Today's Parent, 2016). Infants explore objects with their mouths, so anything they pick up should be too big to swallow. The more chewable and unbreakable a toy is, the safer it will be.

Accidents are always unexpected and, in retrospect, could usually have been prevented. Unintentional injuries are the leading cause of death for children in the United States and globally. Every 1.5 minutes an infant is seen in the emergency department for an unintentional injury (American Public Health Association, 2015). Adults take for granted that they are living in a world designed by adults for adults. They must remind themselves constantly that infants also live in this complex world and that they learn at a remarkable rate, primarily by exploring and playing in the environment. These experiences render them extremely vulnerable to accidents, a major problem and a challenging field for preventive measures.

Accidents occur in many situations: in the home, outside, on the playground, and in automobiles. The use of safety belts prevents infant injury (Figure 17-3). Most accidents, however, occur in the home. Their number and seriousness are closely linked to the infant's developmental stage. Accidents tend to increase with the mobility of the infant, but even a 2-month-old infant can wiggle or fall from a high place. Keeping the environment free from hazards and ensuring caregiver supervision are crucial for this age group.

FIGURE 17-3 Accident prevention for infants in their car seats includes the use of safety belts.

Nurses have the opportunity to help parents and caregivers anticipate and understand the common hazards of early life and provide specific guidance for accident prevention.

Unintentional Injuries

Falls.

Falls are most common after 4 months of age, when the infant has learned to roll over, but they can occur at any age. Falls involving infants happen more often in the home environment, on stairs, from furniture, and out of windows. The best advice is never to place an infant unattended on a raised surface that has no type of guardrails. When in doubt, the safest place is the floor (Gill & Kelly, 2015). Safety tips to assist parents in preventing falls are listed in Box 17-11.

Box 17-11

Safety Tips to Prevent Falls

- Keep sides up and firmly secured when the infant is in the crib.

- Place the infant seat on a stable surface, preferably the floor. The infant should be strapped in securely.
- Check high chairs, strollers, and carriages for safety, and restrain the infant who is active.
- All windows above the first floor should be locked and have operable window guards.
- Clean up food or liquid spills immediately from the floor.
- Remember that polished floors are hazardous, especially when throw rugs are present.
- Close off stairways with doors or properly installed gates, at the top and bottom.
- To prevent falls, set the crib mattress at the lowest adjustment level after the infant can pull himself/herself up and stand.
- Place furniture away from windows and anchor pieces to the wall.
- Avoid the use of baby walkers.
- Never leave an infant alone on a bed, changing table, or piece of furniture.
- Avoid bringing strollers onto escalators.
- Best fall prevention is to watch, listen, and stay near the infant at all times.

From Remedy's Health Communities. (2017). *Preventing falls in babies.* http://www.healthcommunities.com/infant-safety/children/fall-prevention.shtml

Burns.

In the United States, burns are the third leading cause of unintentional injury death in children aged 1 to 14 years, accounting for more than

600 deaths per year in children from birth to 19 years of age. Every day, more than 300 children aged 0 to 19 years are treated in emergency departments for burn-related injuries and two children die as a result of being burned (CDC, 2015g).

Burns are the most frequent and frightening of all accidents during infancy. Most fire deaths occur in the home, and most victims die because of smoke or toxic gases and not because of the burns (CDC, 2015g). Because nearly all burns are preventable, the attendant caregiver can experience severe guilt.

Fire from matches or other sources, hot liquids, ultraviolet light from the sun, electricity or electrical outlets, and heating elements such as radiators, registers, and floor heaters can all cause burns.

Swallowing/choking on foreign objects.

Choking occurs when a foreign object becomes lodged in the throat, blocking air flow (National Safety Council, 2016). Choking is the leading cause of unintentional death in infants (American Heart Association, 2015). Any small object that an infant puts in the mouth has the potential to be swallowed and choked on. More than 65% of deaths from foreign-body aspiration occur in infants. Liquids are the most common cause of choking in infants, whereas balloons, small objects, and foods are the most common causes of foreign-body airway obstruction in children (American Public Health Association, 2015). Parents should be advised that objects such as safety pins, peanuts, beads, coins, hot dogs, paper clips, nuts, corn, buttons, popcorn, chips, apple with peel, and parts of broken toys are frequently swallowed. Many objects can fit into this category and into the infant's mouth. The carelessness of a caregiver, relative, friend, or babysitter in leaving small objects available and within reach, or giving toys unsuited to the infant's stage of development, frequently causes these accidents.

When choking occurs, the adult should place the infant across the adult's knees and deliver five back blows (slaps) followed by five chest thrusts repeatedly until the object is expelled or the infant becomes unresponsive. Abdominal thrusts are not recommended for

infants because thrusts in the abdominal area could potentially damage the relatively large and unprotected liver (American Heart Association, 2015). Cardiopulmonary resuscitation should be performed if the infant becomes unresponsive. The American Heart Association does not recommend use of under-the-diaphragm abdominal thrusts for choking infants younger than 1 year. Prevention of swallowing foreign objects is the best treatment.

The entire balance of safety for infants depends on allowing them plenty of opportunity to explore and play within the environment while protecting them from harmful agents. According to the AAP, the greatest threat to the health of infants is not illness but injuries, many of which can be prevented. The nurse informs the infant's parents, babysitters, family friends, and day care workers about the need to childproof their environments when an infant is present. The nurse can explain ways to promote the safety of these varied environments (Box 17-12).

Box 17-12

Home Childproofing Tips

- Remove any heavy, sharp, or breakable objects from tables and low shelves.
- Bolt bookcases to the wall and remove heavy books to prevent falls.
- Test floor and table lamps to make sure they cannot be pulled over.
- Avoid placing toys, blankets, pillows, or bumper pads in the crib.
- Disconnect unused appliances and wrap up cords.
- Secure all other cords to prevent appliances from being pulled down.
- Safely discard unused and unneeded medicines.

- Avoid referring to medicines as candy.
- Post the National Capital Poison Center telephone number (1-800-222-1222) nearby.
- Store potentially toxic substances out of sight and reach.
- Close reachable outlets with safety covers.
- Avoid leaving an infant unattended in the bathtub, even for a moment.
- Avoid using tablecloths that can be pulled down by a crawling infant.
- Tie drapery and blind cords out of the infant's reach.
- Choose stair gates with openings too small for an infant's head and child-resistant fasteners such as pressure bars.
- Avoid accordion or expandable gates with openings that can trap an infant's head.
- Install smoke detectors and check the batteries at least once a month.
- Use sturdy screens in front of fireplaces.
- Place crib, playpen, and high chair well away from heaters, fans, and electrical outlets.
- Install childproof latches on drawers and cupboards. Store all cleaning compounds and detergents in a high, locked cupboard.
- Keep plants out of an infant's reach, as some are poisonous.
- Buy all medicines in bottles with childproof lids and keep them in their original labeled containers for identification in case of accidental ingestion.

- Install lids on garbage pails and never leave any harmful materials in them, such as sharp can lids or spoiled food.
- Place furniture away from windows and anchor pieces to the wall, such as TVs.
- Check the floor regularly for objects small enough to be swallowed.
- Cut blind cords into two pieces.

From Centers for Disease Control and Prevention. (2016). Safety in the home and community. http://www.cdc.gov/parents/infants/safety.html.

Biological Agents

The fetus is partially protected from some biological agents in the environment by the placental barrier and the mother's defense system. After birth, however, the infant is thrust into an environment that is filled with infectious, disease-causing agents. These bacterial or viral organisms can be found in food, cribs, the air, pets, the parents, and the siblings—literally everywhere (Environmental Protection Agency [EPA], 2015). Even the healthiest environment harbors disease-causing agents. Although the infant cannot escape exposure to these pathogens without being completely isolated, immunizations are given to assist the infant's defense against some communicable diseases.

Acquired Immunodeficiency Syndrome

Human immunodeficiency virus (HIV) is a retrovirus and can be transmitted vertically, sexually, or via contaminated blood products or intravenous drug abuse. Acquired immunodeficiency syndrome (AIDS) is spread by contact with HIV through blood and body secretions. HIV becomes established in cells of the host's immune system called T cells. The T-helper cells are sometimes referred to as CD4+ cells because they have a glycoprotein on their surfaces. CD4+ helps the T-helper cells recognize HIV, but if the CD4+ T-helper cells

are infected with HIV, they cannot coordinate an immune response to the HIV virus. The infant with HIV infection is unable to resist normal infections. Transmission of HIV from mother to infant is the most likely cause of childhood HIV infection. Transmission can occur during pregnancy, at childbirth, or during breastfeeding. For 6 weeks after birth, infants born to HIV-positive women receive the HIV medication zidovudine (Retrovir) to protect them from any infection with any HIV that may have been passed during the birthing process. In addition, because HIV can be spread in breast milk, women with HIV who live in the United States should not breastfeed (AIDS Info, 2015) (see Chapter 16). There is no immunization against HIV infections currently, but frequently preventive options are offered to mothers, and babies are usually delivered by cesarean delivery. Antiretroviral drugs reduce viral replication and can decrease mother-to-child transmission of HIV either by lowering plasma viral load in pregnant women or by providing postexposure prophylaxis in their newborns. In developed countries, highly active antiretroviral therapy (HAART), which usually comprises three drugs from at least two classes, has reduced the mother-to-child transmission rates to approximately 1% to 2%, but HAART is not always available in developing countries (Rivera & Frye, 2015).

Because infants can retain maternal antibodies for HIV infection for as long as 18 months, the diagnosis of HIV infection in an at-risk infant (one whose mother is infected) is extremely difficult. In the last few years, investigators have demonstrated the utility of highly accurate blood tests in diagnosing HIV infection in infants aged 6 months or younger. The standard assay has limited utility in diagnosing HIV reactivity among infants until the age of 18 months, by which time many HIV-infected infants have died. The preferred virological assays for diagnosing HIV infection in infants and children younger than 18 months include HIV branched DNA polymerase chain reaction and HIV RNA assays either by a dried blood spot or by a whole blood sample (Rivera & Frye, 2015). Although signs and symptoms of illness can occur at any time, they usually begin during the first year of life. In infants, the symptoms of the disease include

growth failure, oral candidiasis, recurrent bacterial infections, pneumonia, recurrent fungal infections, chronic diarrhea, and delays in reaching important milestones in motor skills and mental development such as crawling, walking, and speaking. Early recognition and triaging of infants suspected of having HIV infection provide an opportunity for early diagnosis and treatment, which could prevent the adverse impact of rapidly progressive HIV disease (CDC, 2015h).

In response to the urgent need to reduce the number of new HIV infections globally, the WHO and the Joint United Nations Program on HIV/AIDS (UNAIDS) funded research to determine whether male circumcision should be recommended for the prevention of HIV infection (WHO & UNAIDS, 2015). On the basis of the research findings presented, experts recommended that use of condoms and male circumcision be recognized as important interventions to reduce the risk of heterosexually acquired HIV infection in men. There is strong evidence that medical male circumcision reduces the acquisition of HIV in heterosexual men by between 38% and 66% in 24 months. The incidence of adverse events is very low, indicating that male circumcision, when conducted under these conditions, is a safe procedure. Inclusion of male circumcision into current HIV prevention measure guidelines is warranted, with further research required to assess the feasibility, desirability, and cost-effectiveness of implementing the procedure globally. Currently, voluntary medical male circumcisions are being implemented in several sub-Saharan African countries to prevent HIV spread (Wamai et al., 2015). Parents must weigh their decision to circumcise their male infant on the basis of their own values, religious backgrounds, and culture in light of this new information.

Nursing assessment focuses on a careful and complete history of the infant and mother, signs and symptoms of the disease, growth and development history, and psychosocial concerns. Parents are assessed carefully to determine their level of anxiety; knowledge of the disease process, including prognosis, treatment, and transmission; and awareness of resources, support systems, coping strategies, and the

infant's needs.

No other disease causes as much public awareness and panic as does AIDS. Part of this behavior is ignorance. Nurses play a major role in educating the public about the disease process, its mode of transmission, and most of all, preventive measures. Preventive education should begin with young children. Most school health programs include information on HIV/AIDS. School nurses can contribute to the success of these programs, as can nurses working in prenatal clinics, to spread the importance of prevention. Nurses in all settings can engage in research related to HIV/AIDS to gather further clarification of this fatal disease.

Although the infant is not an active participant in the spread of HIV, parents should understand the means by which the virus is transmitted and not allow their infant to become a passive participant because of their own high-risk behaviors.

Immunization

Disease prevention by immunization is a public health priority in *Healthy People 2020* and society as a whole. Progress continues toward the goal of protecting children from serious disease through immunizations. The most recent schedule recommends the rotavirus vaccine in a three-dose schedule at ages 2, 4, and 6 months. The influenza vaccine is now recommended as an annual vaccine for all children aged 6 to 59 months, as well as pregnant women. In addition, varicella vaccines should be administered at age 12 to 15 months, and a newly recommended second dose should be administered at age 4 to 6 years (CDC, 2015i,l). For current-year immunizations, see http://www.cdc.gov/vaccines/schedules/hcp/imz/child-adolescent.html.

The two types of immunization are active and passive immunization. In **active immunization**, all or part of a disease-causing microorganism or a modified product of that microorganism is injected into the body to make the immune system react defensively. This substance is generally a toxin of the disease organism; depending on the virulence and certain other characteristics

of the organism, it is used in the vaccine in a live, killed, or attenuated form (AAP, 2015c). The attenuated form is alive, but its virulence has been reduced significantly by treatment with laboratory procedures that use, for example, heat or chemicals, which reduces the potency of microorganisms. Examples of active immunization include diphtheria, tetanus, and acellular pertussis vaccine; inactivated polio vaccine; and measles, mumps, and rubella vaccine. Active immunity is relatively long lasting, waning over several years if at all.

Passive immunization is accomplished by injection of blood from an actively immunized person or animal. After an individual has been exposed to a disease, a passive immunization is given to prevent the disease from developing. Passive immunizations provide a short immunity, usually 1 to 6 weeks, which will protect the person until the danger of contracting the disease has passed. Passive immunization also helps reduce the severity of the disease when it is contracted. Because of the short duration, active immunization is still needed for a person to remain permanently immune. Passive immunity occurs naturally in newborns when maternal antibodies are passed through the placenta or in breast milk.

The Committee on Infectious Diseases of the AAP and the CDC (2015i) recommend immunization schedules that are revised periodically as new information arises. Table 17-9 lists the current recommendations for healthy infants.

TABLE 17-9

Recommended Immunization Schedule for Infants

Age (Months)	Immunization
Birth	HepB (first dose)
1	HepB (second dose)
2	DTaP (first dose) + Hib (first dose) + PCV (first dose) + PV (first dose) + RV (first dose)
4	DTaP (second dose) + Hib (second dose) + PV (second dose) + PCV (second dose) + RV (second dose)
6	HepB (third dose) + DTaP (third dose) + Hib (third dose) + PV (third dose) + PCV (third dose) + RV (third dose) + influenza vaccine (yearly)
12–15	Hib (fourth dose) + MMR + PCV (fourth dose) + HepA + varicella vaccine
15–18	DTaP (fourth dose)

DTaP, Diphtheria, tetanus, and acellular pertussis vaccine; *HepA,* hepatitis A

vaccine; *HepB,* hepatitis B vaccine; *Hib, Haemophilus influenzae* type b conjugate vaccine; *MMR,* measles, mumps, and rubella vaccine; *PCV,* pneumococcal vaccine; *PV,* polio vaccine; *RV,* rotavirus vaccine.

Modified from Centers for Disease Control and Prevention. (2015). Recommended immunization schedule for birth to 15 months. http://www.cdc.gov/vaccines/schedules/hcp/imz/child-adolescent.html.

Immunization provides one of the most cost-effective means of preventing infection in infants. Immunizations not only help protect those receiving the vaccinations from developing potentially serious diseases but also help protect entire communities by preventing and reducing the spread of infectious agents. Immunization is additionally important because antibiotics cannot destroy viruses; therefore immunization offers the only means of control. Nurses have a special responsibility to keep informed of the recommendations and document all vaccinations given. Emphasis must be placed on educating parents about the importance of immunization. Children need a series of vaccinations, starting at birth, to be fully protected against potentially serious diseases. To motivate parents to have their infants immunized, the nurse can work toward increasing health education to achieve greater health maintenance knowledge, send reminders for upcoming visits and needed immunizations, vigorously advocate that all infants should receive comprehensive health care, including immunizations, provide health services that make immunizations feasible and available, develop a close relationship with the family, and continue surveillance of the immunization status of every infant in the health care system.

Chemical Agents

Drugs

Despite advances such as childproof caps on medications, childproof packaging, increased educational efforts, and increased awareness of commonly ingested substances, deaths attributable to unintentional poisonings still occur. Unintentional poisonings are an unfortunate and usually preventable cause of death and disability in infants and

children. The very nature of a young child predisposes the child to explore the surrounding environment. As children grow and learn to become independent, they are compelled to investigate new and interesting items, places, and objects, such as medications. On the basis of calls to the US poison control centers, each year more than 1 million children younger than 5 years experience potentially toxic ingestions. More than 90% of poisoning exposures occur in homes (Kelly, 2015).

Ibuprofen is the medicine most commonly ingested, with acetaminophen and vitamins close behind. Ibuprofen and other aspirin substitutes are becoming increasingly popular with parents as antipyretics. Vitamins can be harmful; however, many vitamins contain iron, making them potentially lethal. Infants are frequently attracted to vitamins because of their appealing colors, scents, and flavors, especially children's vitamins.

Recent changes in packaging and limits on the number of tablets contained in each bottle have reduced deaths resulting from overdose. Drug manufacturers are using childproof caps increasingly as a safety measure. Despite a concerted effort by manufacturers, childproof bottle caps differ in effectiveness (Ferguson et al., 2015). Frequently the safety caps are adult proof, although children can readily open bottles with them.

This accessibility points to the dangers of medications, regardless of the bottle. All medications must still be secured in a safe place when infants are in the home or visiting other homes. Some additional guidelines to help prevent accidents involving drugs include the following:

- Use a prescription drug only for the purpose and the person for whom it is intended. Do not use medication prescribed for someone else for a similar condition in the infant.
- Discard unused drugs by taking them to dump into trash on toxic dump days; many infants have been poisoned by eating tablets found in the trash at home.
- Request safety caps on all prescription drugs.
- Keep all medicines under lock and key.

- Use the dosing device that comes with the medicine.
- Consider products not thought about as medicine—diaper rash remedies, eye drops.
- Have the telephone number of the nearest poison control center readily available.

The main points to be emphasized in giving parents guidance in accident prevention are to eliminate specific environmental hazards, such as drugs, from exploring infants, and to supervise infants while they play, gradually replacing supervision with safety training (Ferguson et al., 2015).

Plants

Colorful, interesting-looking houseplants add beauty to our homes, but they are often an irresistible attraction to a young infant or child. Infants and small children have a curious nature and cannot keep their hands out of dirt-filled plant pots or resist the temptation of eating leaves from the plant. Houseplants are another source of poison if ingested. Most people fail to think of houseplants as potentially poisonous because people do not consider eating them. However, infants test almost everything by putting things in their mouths, and a number of plants can be deadly when eaten. As a result, plants are one of the leading sources of poisoning of infants, and amateur foragers frequently learn the hard way that not everything that looks good can be eaten. Most plants, however, have an unpleasant taste and therefore are consumed only in small amounts. The effects of unintentional poisonings are typically dose dependent; therefore as children age and their sense of taste becomes more defined, the risk of large-dose unintentional poisonings decreases because they are better able to discriminate the unpleasant taste.

Household plants are frequently placed on the floor, where the leaves or flowers are easy to pull off and taste. The best intervention for plant poisoning is prevention, which, in this case, means previous knowledge. Table 17-10 identifies several common household and

garden plants that are poisonous. The nurse must know which plants are harmful when ingested and must inform parents of the potential dangers to infants.

TABLE 17-10

Poisonous Parts of Common Houseplants and Garden Plants

Plant	Toxic Part	Symptoms
Apple	Seeds	Release cyanide when ingested in large quantities; can be fatal
Azalea	All parts	Nausea, vomiting, dyspnea, paralysis; can be fatal
Buttercup	All parts	Inflammation around mouth, stomach pains, vomiting, diarrhea, and convulsions
Castor bean	Seeds	Burning of mouth and throat, excessive thirst, and convulsions; one or two seeds are near the lethal dose for adults
Croton species	Plant juice	Gastroenteritis
Daffodil	Bulb	Nausea, vomiting, and diarrhea; can be fatal
Dieffenbachia	All parts	Intensive burning and irritation of the mouth and tongue; death can occur when base of tongue swells enough to occlude air passages
English holly	Berries	Nausea, vomiting, diarrhea, central nervous system depression; can be fatal
English ivy	Leaves and berries	Dyspnea, vomiting, diarrhea, coma, and death
Hyacinth	Bulb	Nausea, vomiting, and diarrhea; can be fatal
Iris	Underground stems	Digestive upset
Jasmine	All parts	Hallucinations, elevated temperature, tachycardia, and paralysis
Lily of the valley	All parts	Arrhythmia, mental confusion, weakness, shock, and death
Mistletoe	Berries	Acute stomach and intestinal irritations with diarrhea; can be fatal
Oak tree	Acorns	Kidney failure, gastritis
Oleander	All parts	Digestive upset, bloody diarrhea, respiratory depression, cardiac arrhythmia, blurred vision, coma, and death
Philodendron	All parts	Burning of lips, mouth, and tongue; swelling of tongue; dyspnea; kidney failure; death
Poinsettia	Leaves	Severe irritation to mouth, throat, and stomach; can be fatal
Potato	All green parts	Cardiac depression; can be fatal
Tomato	Green parts	Cardiac depression; can be fatal
Violet	Seeds	Taken in quantity, cathartic effects can be serious to infant
Yew	Foliage, seeds, bark	Nausea, vomiting, diarrhea, dyspnea, and dilated pupils; death is sudden

Modified from Chesnut, V. K. (2012). *Principal poisonous plants of the United States*. Ulan Press; and Kinsey, J. (2016). Ten toxic houseplants that are dangerous for children and pets. HubPages. Retrieved from: http://hubpages.com/living/Dangerous-Beauties-Twenty-Toxic-Houseplants-to-Avoid-Around-Children-and-Pets.

The most prominent groups of plants involved in exposures are

those containing oxalates, and the most common symptom is gastroenteritis. The top 12 identified plants (in descending order) nationally were *Spathiphyllum* species (peace lily), *Philodendron* species (philodendron), *Euphorbia pulcherrima* (poinsettia), *Ilex* species (holly), *Phytolacca americana* (pokeweed), *Toxicodendron radicans* (poison ivy), *Capsicum* (pepper), *Ficus* (rubber tree, weeping fig), *Crassula argentea* (jade plant), *Dieffenbachia* (dumb cane), *Epipremnum aureum* (pothos), and *Schlumbergera bridgesii* (Christmas cactus) (Chesnut, 2012).

The American Association of Poison Control Centers [AAPCC] (2016) lists plants as the third most commonly ingested poison, after aspirin and household cleaning agents. Safety education is stressed at all well-baby visits beginning in the first 6 months of life. Prevention of plant poisoning and other accidents depends on a reciprocal relationship between protection and education that must be related to age. Keep all poisonous substances, medicines, cleaning agents, health and beauty aids, paints, and plants locked in a safe place out of an infant's sight and reach. Find out the names of all the plants in and around the house because if someone ingests one of them, the poison control center will need to know what it is when it is called. Never store poisonous substances in containers other than original ones (e.g., empty jars or soda bottles). Safe behavior is a learned behavior, gradually acquired in a progressive process with increasing age.

When parents are being taught, anticipatory guidance should include ways to prevent ingestions, the phone number for the National Capital Poison Center (800-222-1222), early recognition of common signs and symptoms of poisoning, and the importance of never giving remedies before the poison control center has been contacted. It is also important to discuss with parents and caregivers the importance of storing these medications out of the reach of infants and children, using safety locks on cabinets, and keeping purses (or any other places of storage of these medications) out of the reach of infants and children who are at risk of unintentional poisoning. When parents are provided with anticipatory guidance, particular emphasis must be placed on the prevention of unintentional poisonings. Guidance should be given on the basis of developmental age rather

than chronological age (National Capital Poison Center, 2016).

As nurses, part of our role is that of education. Talking with parents outside the health care arena would be a great start. Girl Scout meetings, meetings of parent-teacher associations, church gatherings, day care centers, and other community-based activities can provide a forum for teaching and learning, and such training sessions could also provide an opportunity for questions to be answered.

Box 17-13 lists specific safety measures for parents to prevent plant poisoning of infants (AAPCC, 2016; National Capital Poison Center, 2016).

Box 17-13

Nursing Interventions to Prevent Plant Poisoning in Infants

- Keep plants out of reach of infants and young children.
- Never eat any part of a plant except the parts that are grown or sold as food.
- Keep jewelry made from unknown seeds or beans away from exploring infants.
- Learn to identify poisonous plants around your house and garden.
- Do not use unknown plants as medicines or teas.
- Pay close attention to infants at play inside and outside.
- Seek help whenever anyone chews or swallows a poisonous plant.
- Be aware that infants are more susceptible than are adults to the effects of poisonous plants.
- Keep the National Capital Poison Center telephone number handy (1-800-222-1222).

From National Capital Poison Center. (2016). Poison and prevention information by age. http://www.poison.org/by-age.

Toxins

Susceptibility to environmental toxicants depends on the child's developmental stage and interactions within the physical, biological, and social environment. Infants are at particular risk of exposure to toxic factors in the environment; as dependent, developing organisms, they are inherently vulnerable. Generally, the exposure of infants to potential toxins is quite different from that of adults because of differences in physical environment, activities, and diet. Daily activities of infants, such as proximity to the floor or carpet inside the home and the lawn or soil outside, hand-to-mouth behaviors, and smaller body size and composition, place them at great risk of exposure to environmental toxins. The floor inside the home is an important microenvironment for infants because their breathing zones are low and many chemicals are concentrated near the floor. Ingestion, inhalation, and dermal exposure can occur. Infants are exposed to a host of environmental pollutants on a regular basis. These exposures occur through all possible environmental media: air, water, soil, and food. Infants have a unique exposure pattern and unique vulnerabilities. For example, some studies identify that the infant's oral habits and unique diet (ingesting more fruits, vegetables, and water than do adults) magnify their exposure to certain agents. Finally, because infants have a longer life span, toxins that have a long latency or cumulative toxicity (such as certain carcinogens) pose a greater risk to them than to adults (Falck et al., 2015).

Pesticides are internationally used harmful chemicals that are used to control pest attack on crops. Commonly pesticides are used to kill insects (insecticides), weeds (herbicides), fungi (fungicides), and rodents (rodenticides). Some pesticides that are used to control insects that feed on cereal grains, fruits, and vegetables are notorious for their slow accumulation in human tissue. Produce washes are available now to rid vegetables and fruits of these potential toxins. Over sufficient time, exposure to relatively small amounts of pesticides can

result in the buildup of toxic quantities and lead to chronic disease in humans. Pesticides pollute water sources and agricultural products, and consumption of their residues by drinking water or the eating of foods may lead to serious health risks (Hashim, 2015). All pesticides have the ability to harm infants if they are exposed to them. The essence to decreasing the health hazards of pesticides is to limit exposure to them by use of precautionary measures and to have knowledge of their chemistry to decrease their hazards.

Lead is another environmental toxin that has no known physiological role in the human body. Lead exposure is a public health concern, especially in early childhood because young children are more prone to practice hand-to-mouth activity and absorb lead. Lead exposure can slow mental development and cause lower intelligence later in childhood. The effects of lead are more toxic on developing nervous systems of infants and young children than on a mature brain (Sharma et al., 2015). Although lead is essentially a contaminant, most people absorb a certain amount through exposure to lead-based paint in older homes, contaminated soil, household dust, drinking water, lead crystal, and lead-glazed pottery. Before 1950 lead-based paint was used on the inside and outside of most homes. It was used to make several colors, including white, and was known to dry to a hard, durable surface. In 1977 federal regulations banned lead from paint for general use. However, homes built before 1977 are likely to contain lead-based paint. Numerous toys made in China have been recalled and deemed unsafe because they contain lead-based paint. Studies have revealed a high lead content in drinking water, dirt, household dust, and soil. Lead in the air comes primarily from automobile emissions (National Institute of Environmental Health Sciences [NIEHS], 2015a). Absorption of lead is closely related to particle size. Airborne lead of small particle size is readily absorbed through the lungs, whereas larger particles fall to the ground. Lead affects practically all systems within the body. At high levels, lead can cause convulsions, coma, and even death. Lower levels of lead can adversely affect the brain, central nervous system, blood cells, and kidneys.

Infants are vulnerable to lead exposure for several reasons. In proportion to their weight, infants inhale more air and more lead than do adults (EPA, 2015). Additionally, infants breathe closer to the ground, where a higher concentration of lead is located. Their dust-raising play and habit of putting their hands in their mouths add to their lead consumption; they also have a greater rate of gastrointestinal absorption of lead and other chemicals than do adults. Both exercise and blockage of the nasal passages increase mouth breathing, and the mouth is a far less capable filter than the nose. Mouth breathing, coupled with their greater frequency of respiratory tract infections, exposes infants to a greater amount of environmental toxins. The growing prevalence of asthma is also evidence of environmental exposure to lead and other pollutants.

Asthma is an inflammatory disease of the lung. Approximately 7 million children have asthma. Asthma rates have doubled in the last decade, and death rates from asthma have increased in recent years. The reality is that we do not know why asthma is becoming more prevalent, but air pollution is a contributing factor. A few select steps to decrease indoor allergens to prevent asthmatic attacks include vacuuming carpets and upholstered furniture weekly; washing sheets, blankets, and towels in hot water weekly; cockroach elimination; and placing allergen-impermeable covers on pillows, box springs, and mattresses (NIEHS, 2015b).

Human potential and development are clearly important natural resources, and a growing body of evidence now links increased lead exposure to impaired intellectual performance and potential. Clinical lead poisoning affects many children, but it is preventable; excess lead in the infant's environment is made by, and should be eliminated by, human beings. Childhood lead exposure has been linked to numerous health problems, including learning disorders, attention deficit disorder, and hearing loss. Researchers suspect that there is no threshold of exposure to lead for many of these adverse outcomes, especially as a neurotoxicant (NIEHS, 2015a). Progress has been made in reducing blood lead levels in infants and young children. But still today, more than 300,000 American children remain at risk of lead

exposure. Many infants and young children live in poverty and old rented dwellings, which can lead to or exacerbate the effects of lead exposure. The following factors have contributed to the reduction of blood lead levels (USDHHS, 2010):

- Decline in lead used in gasoline
- Decline in manufactured food and soft drink cans containing lead solder
- Ban on leaded paint for residential (indoor) use
- Established standard for lead exposure in industry
- Ban on lead-containing solder in household plumbing
- Implementation of lead poisoning prevention programs
- Ban of toys manufactured in China containing lead-based paint

Parents need education regarding measures that can reduce their infant's exposure to lead:

- Keep areas in which the infant plays as dust-free and clean as possible.
- Do not remove lead paint yourself.
- Do not bring dust into the home.
- If work or a hobby involves lead, change clothes and bathe before entering the environment of infants (e.g., day care centers).
- Do not burn painted wood in a fireplace.
- Eat a balanced diet rich in calcium, iron, and vitamin C.

Infants do not necessarily escape noxious chemicals when they are indoors. The levels of contaminants that cause air pollution are approximately the same indoors as they are outdoors, with perhaps higher indoor concentrations of carbon monoxide, nitrogen dioxide, and various hydrocarbons from tobacco smoke; poorly ventilated heating and cooking equipment; and aerosol sprays. There are radon checks and carbon dioxide detectors that can be used to assess the presence of these contaminants. Many consequences of exposure to air pollution may not be observed during infancy but can surface in problems that affect both physical and mental well-being over a

lifetime.

Among the acute illnesses of infancy, respiratory disease is ranked first, representing between 50% and 75% of all childhood diseases (NIEHS, 2015c). In addition to the inconvenience and incapacity induced by respiratory diseases, medical costs are high. Dirty air aggravates and, in some cases, causes nearly all respiratory problems. Infants with chronic respiratory disease can become adults with respiratory problems.

Water pollution can cause gastrointestinal disturbances in the infant. Parents and health care providers are quick to blame food, teething, or a virus for simple diarrhea, when the underlying cause may come from the kitchen tap. Numerous strong chemicals are used today to purify drinking water. These chemicals can irritate the delicate lining of the gastrointestinal tract and cause disturbances. Nurses encourage parents to boil all water for 20 minutes before they give it to their infant to help eliminate any potential problems.

Toxicants are widely dispersed throughout the environment of infants. It is essential for nurses to understand the potential routes of exposure, toxic effects, and strategies for prevention of exposure so as to provide anticipatory guidance to parents and family members.

Motor Vehicles

This section considers the effects of motion or action of forces on the infant; the focus here is on motor vehicle accidents.

Automobiles present a danger to people of all ages, but especially to infants. Usually an infant is injured because of improper restraint inside the automobile. Many parents have been misled by thinking that it is better to be thrown clear of an accident than it is to be restrained. Many also think that it is safer to hold an infant on the lap in the front seat rather than to have the infant restrained in the back seat. On the contrary, these practices increase the probability of a fatality. A free-moving child not only distracts the driver but also means the child is in a more vulnerable position for being thrown.

Adult seat belts are unsuitable for infants or children younger than 4 years because their pelvic structure is small; the AAP recommends

that safety seats for infants be used (USDHHS, 2010). The AAP and the National Highway Traffic Safety Administration recommend four evidence-based sequential steps to properly protect infants and children in passenger vehicles for children from birth through adolescence: rear-facing car safety seats with harnesses for most infants up to 2 years of age; forward-facing car safety seats with harnesses for most children through 4 years of age; belt-positioning booster seats used with a three-point belt restraint for most children through 8 years of age; and lap-and-shoulder seat belts for all who have outgrown booster seats. In addition, a fifth evidence-based recommendation is for all children younger than 13 years to ride in the rear seats of vehicles (Klinich & Manary, 2015). All children should be in the back seat because of the potential danger posed by air bags. Infant safety in motor vehicles depends entirely on the responsible adults.

Each year some infants die of heat stroke after being left unattended in motor vehicles. More than half the deaths are of children younger than 2 years. On days when ambient temperatures exceeded 86°F, the internal temperature of a vehicle quickly reaches 120°F to 140°F (Sims, 2015). At those temperatures, children are at great risk (http://pediatrics.about.com/od/summersafety/a/heat_illness.htm) as they can lead to a fever, dehydration, seizures, stroke, and death.

Even at relatively cool ambient temperatures, the temperature can rise inside the vehicle to more than 100°F, which places the infant at risk of hyperthermia. Vehicles heat up rapidly, with most of the temperature rise occurring within the first 15 to 30 minutes. Leaving the windows opened slightly does not significantly slow the heating process or decrease the maximal temperature attained (Kids & Cars, 2015).

Nurses can take the lead in increasing public awareness and improving parental education regarding heat rise in motor vehicles. The take-home message here is to never leave an infant alone in a motor vehicle. Make “look before you leave” a routine whenever you get out of the car. The nurse can also suggest the automobile safety precautions listed in Box 17-14. Much of automobile safety is common

sense, but the nurse must cover all areas in anticipatory preventive teaching. The importance of automobile safety cannot be overemphasized.

Box 17-14

Automobile Safety Precautions

- Be a good role model. Make sure you always wear your seat belt.
- Never leave a child unattended in a parked car or around cars.
- Never hold a child in the lap in the front seat.
- *Look before you lock* the car to make sure no child is left behind.
- Always use an infant car seat that is properly installed by following the manufacturer's instructions.
- Keep car doors and windows locked, even in driveways or garages.
- Use safety restraints for passengers and the driver.
- Do not be distracted by an infant while driving.
- Continue to use car seats as directed by the manufacturer; then use seat belts.
- Never place an infant in a rear-facing car safety seat in the front seat of a vehicle that has a passenger air bag.
- Make sure the seat belt is routed through the correct belt path for adult seat belts.
- Always lock your car and secure the keys so that children cannot access keys.
- Install a trunk release mechanism so that children will not be

trapped in the trunk.

- Take the child out of the car seat first, and then worry about getting other items (e.g., groceries) out of the car.
- If you see a child alone in a car, get involved. Call 911 immediately and get the child out of car immediately. It may save the child's life

From American Academy of Pediatrics. (2016). Safety & prevention: Car seats. https://www.healthychildren.org/English/safety-prevention/on-the-go/Pages/Car-Safety-Seats-Information-for-Families.aspx.

Radiation

In its broadest sense, radiation means the transfer of electromagnetic waves or energy through space (CDC, 2015j). Radiation of all types presents a potential hazard in the infant's environment. The risk level depends on the amount of radiation and the length of exposure and on the particular tissues involved. The infant's rapidly growing and immature cells are especially vulnerable.

The infant is exposed to two basic categories of radiation: natural background radiation, which comes from cosmic rays and radioactive material existing naturally in the soil, water, and air; and human-made radiation, which includes X-rays and radiation from nuclear power plants, microwave ovens, and other electronic devices found in the home (USDHHS, 2010). Infants have a developing immune response. As their immune system develops, immunity occurs in response to external factors such as the environment. Their exposure to ultraviolet radiation alters the development of the immune system, leading to long-term implications for suppression of immunity in adulthood (March of Dimes, 2015).

Determinants of Health

Social Factors and Environment

Community and Work

As infants grow and develop, their boundaries extend beyond the home environment. Many mothers and fathers of infants return to the workforce, placing the infants in community day care centers. Day care refers to the care provided for infants in a center-based facility. It involves the caring for and supervising of infants by someone other than the parent or guardian.

Today few young families can escape financial burdens. The two-income and single-mother families are ways of life, and the trend will continue. With more than half of all American mothers working outside the home, the need for child care service is growing. This situation is usually an emotional issue for families; the separation process can be traumatic for both the infant and the parent.

Findings from social science research regarding the effects of day care on an infant's development and health can be summarized as follows: little evidence suggests that day care permanently enhances or slows intellectual development; day care can be used, even from earliest infancy, without damaging the mother-infant relationship; and day care can lead to a slight increase in minor illnesses, but excluding ill infants from the center is not an effective means of reducing the spread of illness. The day care environment must promote and positively support the infant's development and the infant's interaction with space, materials, and people (Nefer, 2015).

The question of how old an infant should be before being placed in day care is frequently asked of health professionals. Many experts believe that a mother and infant should have 4 to 6 months together before the mother returns to work. Brazelton and Sparrow (2015) make a good case for the mother and infant transitioning through four stages of attachment together before the mother returns to work:

- In the first stage, which takes 10 to 14 days, the infant learns to be

attentive to the mother, and the mother learns cues from the infant about being both ready for and tired of attentiveness.

- The second stage, which lasts 8 weeks, is a stage of playful interaction, when the mother learns how to recognize the infant's nonverbal cues and helps the infant maintain the alert state.
- The third stage, from the 10th week to the fourth month, is when the mother and infant learn to play games together.
- During the fourth stage, which occurs in the fourth month, infants rapidly learn about themselves and their world. A mother, when possible, should spend the first 4 months with her new infant.

A nationwide survey of family day care found that nearly 50% of all infants in day care centers in the United States are cared for in one of three types of arrangements (Clark, 2014):

- Private homes that provide informal day care to infants of relatives, friends, and neighbors
- Regulated independent care licensed by state agencies
- Regulated, sponsored care provided by licensed workers operating as part of home networks under umbrella agencies

The nurse has a vital role in assisting families with infants who need day care. Many factors are reviewed when a family is looking for an appropriate day care program; the nurse can counsel and guide the family in its search. The means by which the nurse counsels and guides the family in selecting a day care center are as follows:

- Promote awareness of the three types of day care available in their local communities.
- Counsel parents on questions to ask employees of a prospective day care facility (AAP, 2015d) (Box 17-15).

Box 17-15

Prospective Day Care Facility Questions

- Is the center licensed by the state?

- Is the day care facility open all year?
- Are all children required to have immunizations before they begin?
- What are the qualifications and credentials of the staff here?
- What hours is it open?
- How long has the center been in business?
- What is the center's licensed capacity?
- How flexible are you with pickup and drop-off times?
- How many children are present at the center?
- What is the age range of children at the center?
- What is the teacher-to-child ratio? (For infants, 1 : 3 is recommended.)
- Describe the day care program.
- What meals are served?
- What is the cost?
- Are there openings?
- Do you have webcam capability so I can view my infant during the day?
- What are the qualifications of the caregivers?
- Are the caregivers happy and interacting with the infant?
- Are infants content?

- What supplies would I need to bring for my infant?
- Are parents welcome to drop in?

From Brightwheel. (2016). What to ask on a daycare center tour. http://mybrightwheel.com/what-to-ask-on-a-daycare-center-tour/; Porpora, T. (2016). Five important questions to ask infant daycare center. *About parenting.* http://workingmoms.about.com/od/childcareissues/a/5-Important-Infant-Daycare-Questions.htm.

- Help parents learn ways to cope with the separation behaviors manifested by their infant:

- Remain calm in the situation.
- Attempt to reduce the number of adults who interact with the infant and always introduce them.
- Instruct parents to ask the question: Where do the infants sleep and are they separate from older children? Exposure to older children increases the risk of infection.
- Encourage the parents to bring an infant's special cuddly toy from home to the day care facility to promote security.
- Listen to the parent's understanding of the separation and expected behaviors.
- Reassure parents that it takes time for the infant to make the transition from the parent to another

caregiver and vice versa.

- Emphasize that at certain developmental levels stranger anxiety may be heightened (8 months), and separation behaviors of crying and clinging may be repeated.

- Work toward promoting a good relationship among parents, the infant, and the caregiver by providing opportunities for open discussions of concerns.

Culture and Ethnicity

Culture is defined as a set of learned values, beliefs, attitudes, and practices that are passed from generation to generation (Polan & Taylor, 2015). Culture plays an important role in influencing an infant's development, and what is considered "normal" development differs greatly from one culture to the next. Culture defines how health care information is received, how rights and protections are exercised, what is considered to be a health problem, how symptoms and concerns about the problem are expressed, who should provide treatment for the problem, and what type of treatment should be given. In short, culture is the lens through which one views the world, affecting everything that an individual and that individual's family perceives and does.

The developing infant is subject to the influences of culture from the moment of conception. Partly because of the long dependency period, the family environment is the setting within which the infant experiences overall cultural attitudes. The lives of infants tend to be more under the direct control of parents or other caregivers than the lives of older children, who are often actively involved in selecting their own environments through contacts with peers, teachers, and other adults. The special demands of infancy require extensive and

specific caregiving routines across cultures. Effective parenting styles also vary as a function of culture. The parents' perceptions of illness, wellness, roles, childrearing practices, religious values, language, and health practices are all modeled for the infant. In short, culture helps form the infant's view of the world (Boundless, 2015).

The family's ethnicity includes ideas about health, illness, food preferences, moral codes, and family life that persist across generations and survive even the upheaval of coming to a new country. All cultural groups confront repeated challenges as they transfer their families from familiar to unfamiliar surroundings. Infants are exposed to an appropriate mode of behavior that is in accordance with their family's cultural standards. By observing and imitating family members, infants take cues for behavior. These perceptions are then incorporated into their own self-concepts (Calkins, 2015).

In attempting to foster trust with diverse populations, nurses need to help women and their families feel comfortable enough to engage in a dialogue and share information. One approach is being careful not to prejudge as foolish or ill-conceived specific cultural practices and beliefs about health care. For example, a perinatal nurse describes a practice common in Hispanic culture in which an infant who has a sunken fontanel is held upside down by the feet to “fill” the hole. Instead of deeming such a practice foolish and scoffing at it, the nurse should let the families know that a more effective practice is to also “give the infant lots of water, or human milk, or formula, … [and] make sure that the infant gets lots of liquids” (Swota & Hester, 2011). With such an approach, families are not embarrassed to let nurses know about their traditional cultural practices. This will help bridge the gap and build trust in their relationship.

To assess and plan appropriate interventions for different ethnic groups, nurses must be aware of their own cultural backgrounds. An important consideration is to examine all customs and values in relative terms, seeing none as either good or bad (Box 17-16). Change is inevitable in family life, whether it is resisted or welcomed. An important function of the nurse is to help families monitor the rate of

change that is acceptable to various members and reach a consensus.

Box 17-16

Factors That Facilitate Multicultural Health Care by Nurses

- Self-exploration of values and beliefs concerning other cultures and their beliefs
- Knowledge of the historical experience, recent and long term, of ethnic groups that live in the community
- Demographic data that include family size, socioeconomic status, and future expectations that are characteristic of diverse ethnic groups
- Understanding and sensitivity to cultural health care practices different from their own
- Recognition of folk beliefs and cultural attitudes toward health and illness
- Awareness of the nature of problems encountered by ethnic group members when they enter the health care system, including fear and distrust of health care professionals, language barriers, and discrimination by caregivers

Culturally competent nursing interventions have been shown to improve outcomes in those seeking care. The need for culturally appropriate nursing care was identified as a key area of intervention by WHO (2015d). Research has identified several strategies that nurses can use that improve communication and reduce stress for culturally diverse populations: answering questions carefully, teaching by demonstration, and "taking time to explain in simple English." In addition, if women felt that the staff truly cared for their

infant, this facilitated communication across multiple barriers because they "felt safe to ask questions" or express needs (Lee & Brann, 2015). Thus nurses who are mindful of the specific views of a culture respect the boundaries of the particular cultural perceptions, beliefs, and practices. Culturally competent nurses have achieved efficacy in communication skills and incorporate health care practices and beliefs of a particular culture in health care plans. Furthermore, respect for the individual's cultural values is viewed as essential if the nurse is to successfully help the family achieve a state of health and wellness.

The nurse identifies the power structure within a given cultural group. This knowledge may help dictate which family member to approach with the health teaching. Although the nurse might assume it would be the infant's mother, this may not necessarily be the case. Among some Native American tribes, the grandmother, not the parents, has the authority over the grandchildren. In many Latino cultural groups, the infant's father, not the mother, makes decisions about the infant's welfare (Andrews & Boyle, 2015). The nurse assesses the cultural groups' practices and beliefs before planning interventions. Improving the quality and safety of nursing care for culturally diverse women globally should be the primary goal of all perinatal nurses. Approaches to infant care practices differ among cultural groups (Box 17-17: Diversity Awareness).

Box 17-17

Diversity Awareness Box

Quick Guide for Cross-Cultural Nursing Care

The dominant American attitudes about infants and approaches to infant care have undergone many changes in the past several years. With the increased numbers of women in the workforce, fathers are becoming more involved in infant care, and day care for infants is increasing. Although children are valued, and raising children within the nuclear family remains a priority, an increasing number of American women are focusing on careers, delaying childbirth, and

limiting family size.

Members of some cultures view childbearing and childrearing differently. The birth of a child is crucial for many Hispanic, Navajo, black, Middle Eastern, and Mormon women, whose social role and status are attained through reproduction within the marital relationship. Preference for a male child exists among families of many cultures, particularly Middle Eastern and Asian cultures (Roudsari et al., 2015).

In the dominant American culture, an infant is frequently wrapped warmly in blankets, placed in an infant seat or stroller, and put to sleep in a crib in a room separate from the parents. Mothers from other cultures may choose to carry or wrap their infants differently; women from some cultures carry their infants with them at all times and sleep with them. Southeast Asian infants may be carried in a hip sling or a blanket carrier. Native American infants are often carried in a cradleboard (a wooden frame into which an infant is bundled and tied). The cradleboard is properly blessed before it is used and can be carried, attached to the mother's back, hung from a tree, or propped up to keep the infant comfortable, safe, and secure (Andrews & Boyle, 2015).

Cultural beliefs and practices are continually evolving and changing. Nurses acknowledge and explore their meanings with all the families they meet. Nurses work actively to reduce the experience of culture shock for ethnic minority families, remembering that American medical beliefs and practices may appear strange to others. All behavior must be evaluated from within the context of the family and the family's cultural background and experience.

Nurses must facilitate health-promoting attitudes and practices and show empathic concern and respect for individuals of all cultural backgrounds. By incorporating the assessment of cultural beliefs and practices into the individual's plan of care, nurses can demonstrate respect and take a step forward in developing culturally appropriate patterns of caring.

In American culture the number of women choosing to breastfeed has steadily increased in recent years. Many factors are involved in

the decision-making process. Nurses who care for families of newborns are aware of the multiplicity of factors influencing feeding choice and encourage and support parents in their decisions to promote the health of newborns.

The family is the primary health care provider for the infant. The family determines health promotion for the family, including when an infant is ill. Many cultural groups choose between the traditional or folk beliefs that they believe to be appropriate to them and Western medical treatment. The Vietnamese use both. For example, to decrease an infant's high temperature, a basil leaf is tied to the wrist with a piece of cheesecloth. For colic, a silver coin is dipped in wine and rubbed or scratched on the infant's back. Nurses are cautious in imposing their own values, beliefs, and attitudes on others. Rather than judging people, the nurse ascertains how each family's values and beliefs influence health outcomes.

The nurse remembers that all behaviors must be evaluated from within the context of the family's cultural background and experiences. Nurses who strive to foster health-promoting attitudes and behaviors begin at the most basic level: empathic concern and respect for the individual. By incorporating the assessment of cultural beliefs and practices into the infant's plan of care, nurses demonstrate respect, reduce alienation, and take a step toward developing culturally appropriate patterns of health promotion. Respecting another's language and religion is extremely important.

From Andrews, M. M., & Boyle, J. S. (2015). *Transcultural concepts in nursing care* (7th ed.). Philadelphia: Lippincott Williams & Wilkins; Roudsari, R. L., Zakerihamidi, M., & Khoei, E. M. (2015). Socio-cultural beliefs, values and traditions regarding women's preferred mode of birth in the north of Iran. *International Journal of Community Based Nursing and Midwifery*, *3*(3), 165.

Language

Language is an important medium for understanding and working together. The nurse may avoid or tend to mumble a person's name when it is foreign; people hesitate to express themselves when the material is unfamiliar. The nurse must consider how the individual

who speaks a different language feels about being unable to express thoughts and feelings or to understand what is being said. Both parties may play the avoidance game.

The nurse takes steps to remove communication barriers, including the following:

- Using a professional interpreter to help in the communication process
- Using pictorial flash cards in the individual's native language to assist in explaining instructions
- Sending a health care worker to an educational center or school to learn the basics of the language to help in the interpreting process in the health care facility

Even a person who speaks the nurse's language may not understand and comprehend instructions given by the nurse. The negative impact of poor communication is huge, resulting in poor health outcomes, health disparities, and high health care costs. The importance of good health communication is relevant to all populations seeking care, including those from culturally and linguistically diverse backgrounds (Andrews & Boyle, 2015).

Religion

In this pluralistic and democratic society, Americans are confronting the ethical and religious values that impinge on health care services. Some providers believe that religion plays no role in individuals' health care practices; therefore they eschew people's religious or ethical concerns and deal mainly with the physical or psychological problems at hand. However, the individual's religious and ethical concerns are generally the major source for human values when health care services are being evaluated.

Religious beliefs can become risk factors when they affect decisions concerning treatment. An example may be the parents who refuse a blood transfusion, surgery, or other medically indicated treatment required to save their infant's life. A court order is needed in many instances to treat these infants. The decision is the parents'

responsibility, based on their customs and beliefs, and should be respected. Deciding not to offer an opinion may be extremely difficult, but usually the opinion is unwanted. Religion is often a powerful force, and when the nurse causes conflict and interferes, a gap can be formed. This gap may force the parents to seek nonprofessional health care to help them with their health-related and religious ideas about birth, death, stress, birth control, and other matters. To work successfully with an individual, the person's religious background should be investigated and understood thoroughly. Most nurses recognize that attending to the spiritual needs of families enhances the overall quality of their nursing care and the satisfaction of their care recipients.

Levels of Policy Making and Health Legislation

Enormous strides have been made in infant health in the past decade: many common, lethal infections have been eradicated (smallpox), malnutrition is seldom seen, and perinatal and infant mortality rates continue to decline. Health and well-being have become generally accepted rights of everyone, without regard to race, gender, age, economic or social status, or creed. The federal government has pledged to promote the general welfare of the United States in the belief that it belongs to everyone.

To fulfill this pledge, several goals were established. One of these concerns is infant health. The goal, as described by the USDHHS (2010), is to "improve the health and well-being of women, infants, children and families."

The infant mortality rate has been on a steady decline since the turn of the century, a result of better infant nutrition, improved technology, improved housing, and improved prenatal, obstetrical, and pediatric care (USDHHS, 2010). To meet the goal of improving infant health, major health problems in this age group must be reduced. A major hazard for infants is low birth weight. To address this problem, factors that increase the risk of low birth weight in infants must be identified

(Johnson et al., 2016).

Many of these factors can be prevented, or risks can be identified early and managed to prevent low-birth-weight infants. The major focus for prevention is prenatal care for all women.

Another major threat to infant survival is congenital disorders, such as malformations of the brain and spine (e.g., microcephaly and myelomeningocele), congenital heart defects (e.g., ventricular septal defects), and combinations of malformations, such as Down syndrome or Tay-Sachs disease. Although some congenital abnormalities cannot be prevented, others can be detected by performing prenatal screening and promoting research to determine their cause.

Other factors identified by the USDHHS (2010) and *Healthy People 2020* that contribute to the high infant mortality rate are injuries at birth, SIDS, accidents, respiratory distress syndrome, and inadequate parenting.

The federal government's plans to attain the goal of healthy infants are as follows:

- Promote family planning services such that all pregnancies are planned and all infants are wanted.
- Provide pregnancy and infant care services through Maternity and Infant Care (MIC) projects to high-risk populations. The Special Supplemental Nutrition Program Women, Infants, and Children (WIC) improves the nutritional status of both the mother and the infant.
- Encourage educational efforts by schools, health providers, and the media to promote prenatal care.
- Promote massive immunization efforts such that each infant is protected from communicable disease.

Nursing's role.

Nurses have important roles in promoting change in response to a continually expanding knowledge base, consumer health care needs, and governmental legislation. By actively participating in groups involved with health planning, the nurse helps make governmental policy more responsive to infants' health care needs. Health

promotion essentially relates to collective or population well-being, which is wholly compatible with all the nurse's roles. Nurses need to work together with other professionals, agencies, and local people to improve the health and well-being of infants and all people (Christie et al., 2015).

The nurse's role in the development of health care policies has the following three stages: identifying resources for the community to meet its specific needs; planning for resources not available to the community; and coordinating the resources available to the community to promote better use of them.

The nurse can become a member of a health planning council, a concerned citizen's group, or an advisory group to a local legislator or to a state health department grant task force. In this capacity, the nurse's responsibility is to inform the other committee members. Because nurses have firsthand experience with many community needs, they are in a good position to speak out and inform others.

The nurse within the community also has several resources available to assist when a need is identified to promote the infant's health, including resources on the federal level (USDHHS), state level (public health department), local level (MIC clinics and well-baby clinics), and community groups (Parents Anonymous, hotlines, La Leche League, March of Dimes, and SIDS groups).

Coordinating for resources, the nurse actively participates in assessing the availability of services within the community and makes recommendations to consolidate or expand existing services. Increasing public awareness of community resources, their services, and existing needs is the basis of the nurse's role in developing policy.

Economics

Virtually every major health problem is found more frequently in segments of the population with low income than in high-income groups. The infant mortality rates in low-income families remain significantly higher than those in high-income families, despite an overall decrease in the infant mortality rate nationally (CDC, 2015k; USDHHS, 2010).

In the United States, roughly 45% of children are born into poor or low-income families, and their health suffers when basic needs such as food, housing, and health screening and vaccinations are not met (AAP, 2015e). Parents with low incomes are often unaware of their infant's developmental needs; they are frequently faced with many environmental and social stresses that demand their time, energy, and other resources (Rapaport, 2015). Many parents have so many unfulfilled needs of their own that they cannot meet their infants' needs. In many cases, infants from families in poverty have delayed language development. With limited educational and life experiences, their parents are often unable to be ideal models for language development. Infants learn early language sounds from their parents, but their attempts at language must be reinforced.

Armed with the knowledge of how economics can affect the infant's growth, development, and health status, the nurse, before deciding on interventions, assesses the family situation by performing the following tasks:

- Establish a relationship with the family to obtain pertinent information.
- Evaluate the home environment in which the infant interacts.
- Elicit the parents' health perceptions about their own health and that of the infant.
- Offer assistance for the family to navigate the health care system for their infant
- Complete a thorough physical examination of the infant to identify any problem areas.
- Identify community resources that are available to the low-income family.

The take-home message is that poverty is like any other epidemiological exposure in infants that has health consequences. To the extent that nurses can reach out to these families, they may have a real positive impact on those infants' lives going forward.

Health Services/Delivery System

The US health care delivery system is diverse and large; many different sectors merge to provide infant care. Within this enormous, multidisciplinary system, the nurse is an advocate who facilitates the family's passage through the many facets of care. Table 17-11 lists a suggested schedule for health-promotion infant care.

TABLE 17-11

Suggested Schedule for Health-Promotion Infant Care

Age (Months)	Promotional Activity
1	Complete physical assessment: PKU test Immunization: HepB (second dose) ***Parent discussion includes:*** Basic infant needs: to be touched, held, fondled, rocked, and talked to Appropriate toy: colorful mobile Nutrition: formula or breast milk
2	Complete physical assessment Immunizations: DTaP (first dose), Hib (first dose), PV (first dose), PCV (first dose), RV (first dose) ***Parent discussion includes:*** Placing infant in prone position to allow lifting of head Need of infant to be exposed to a variety of stimuli within environment Need of infant for change of scenery Colic and other common problems
4	Complete physical assessment Immunizations: DTaP (second dose), Hib (second dose), PV (second dose), PCV (second dose), RV (second dose) ***Parent discussion includes:*** Stimulation of infant Providing a mirror in which the infant can see reflection Being talked to and played with Appropriate toy: rattle
6	Complete physical assessment Immunizations: DTaP (third dose), Hib (third dose), HepB (third dose), PV (third dose), PCV (third dose), RV (third dose), and influenza vaccine Laboratory work: hematocrit level ***Parent discussion includes:*** Accident prevention Teething and use of cool rings Allowing infant to crawl to explore environment Stranger anxiety
9	Complete physical assessment ***Parent discussion includes:*** Accident prevention Dental caries prevention: cleaning teeth with gauze daily Infant's need for space to crawl about Use cup if weaning
9	Use of finger foods Playing games with infant: pat-a-cake, peek-a-boo, waving bye-bye, and shaking hands Appropriate toys: blocks, stack toys, and jack-in-the-box

	Fear of strangers
12	Complete physical assessment Immunizations: MMR, PCV (fourth dose), Hib (fourth dose), varicella vaccine, HepA (first dose) Laboratory work: complete blood count ***Parent discussion includes:*** Accident prevention Getting into things Infant's need to touch and investigate environment, with supervision Parent's need to read, show pictures, and repeat body parts to infant Infant's need for limited independence Sleeping patterns Appropriate toys: sets of measuring cups, nesting toys, pots and pans, and wooden spoons
15	Complete physical assessment Immunization: DTaP (fourth dose) ***Parent discussion includes:*** Negativism as normal aspect of development Age of curiosity in infant Toys appropriate for age: push-pull toys and ball Accident prevention Elimination patterns Discipline: stress positive aspects of behavior, when possible
18	Complete physical assessment Immunization: HepA (second dose) ***Parent discussion includes:*** Accident prevention Begin toilet training, if child is ready Encouragement of vocalization Socialization with other small children Importance of reading to child Setting limits on behavior Coping mechanisms of parents

DTaP, diphtheria, tetanus, and acellular pertussis vaccine; *HepB,* hepatitis B vaccine; *Hib, Haemophilus influenzae* type b conjugate vaccine; *MMR,* measles, mumps, and rubella vaccine; *PCV,* pneumococcal vaccine; *PKU,* phenylketonuria; *PV,* polio vaccine; *RV,* rotavirus vaccine.

From American Academy of Pediatrics. (2016). AAP schedule of well-child care visits. https://www.healthychildren.org/English/family-life/health-management/Pages/Well-Child-Care-A-Check-Up-for-Success.aspx.

The value of health promotion and preventive health care has been validated; it is cost-effective and is here to stay. As nurses' roles continue to expand within the various parts of the health care system, their duty is to keep pace with the needs, concerns, and available strategies (Clark, 2014; Stanhope & Lancaster, 2014). Because many conditions that cause morbidity or death in infants are preventable when health-promotion practices are used, nurses have the mission of working within the health care system to promote infant health

(USDHHS, 2010).

Nursing Application

Nurses can do more to ensure the health of our youngest and most vulnerable population. It is the responsibility of all nurses to make health-education and health-promotion activities an integral part of their professional role. The primary role of the nurse in promoting the health of an infant is to provide the family with education during the most critical developmental period. Initial health-promotion efforts should focus on the nutritional needs of the infant during the first 18 months of life. Basic principles of biological growth and development set the stage for appropriate developmental tasks and psychological growth in the coming months. Nurses can make a difference in the lives of infants and their families by encouraging early and adequate prenatal care for the mother, supporting the transition from the hospital to the home, providing increased access to infant care services, and supporting childhood health surveillance.

The nurse promotes the health of the infant through his or her interactions with the parents as the infant is dependent on them for care. The nurse is in a position to encourage practices in the home that create the optimal conditions for normal growth and development. An important starting point for the nurse is to teach new parents about the nutritional value of breastfeeding and to encourage those efforts. Professional support and education play a vital role in increasing the rates of breastfeeding women.

Following a routine immunization and well-child health visit schedule is another aspect of health promotion for the infant. Nurses play a role in this task by educating parents about the importance of immunization. In addition, nurses should remain informed about the immunization recommendations and assist the family in maintaining documentation of vaccines administered. If cost or access to care is a factor, families can be referred to free or low-cost vaccination clinics.

Injuries and accidents are a major concern for the infant population. Accident prevention and safety are topics that should be addressed by the nurse when working with families. Although it is difficult to

address the many ways in which an infant can be injured, nurses should be prepared to educate parents about the most common hazards. Some of the educational topics that can be addressed include fall and burn prevention, choking hazards, unintentional poisonings, environmental hazards, and automobile safety. In addition, a significant source of illness in infants and children is associated with infectious diseases from either a bacterial or a viral source. Particularly in younger infants, parents should be taught about the importance of frequent handwashing, avoidance of sick contacts, and signs and symptoms of illness that require immediate medical attention.

Essentially, health promotion should be viewed as an umbrella concept, which encompasses all health-related activities that contribute to the formation of a state of health in that individual or community. It should include education, disease-prevention, and environmental-health promotion-measures. The health-promotion goals of the nurse working with infants are met through the family. The nurse must ascertain the health perceptions and motivation of the family, including the use of good or bad health practices. The family must be motivated to provide good health practices for the infant. As the nurse plans health-promotion activities for families of infants, it is imperative that factors influencing health perception are identified. The ability of the nurse to provide a supportive relationship with the parents is a key element in facilitating successful infant development. The nurse working with this population has a unique opportunity to influence the health status of both the infant and the family for years to come.

The leadership of nurses in collaboration with other health care professionals will be key to improving the health of future generations. Whereas there is still room for improvement in the United States, many of the existing pediatric programs of care offer solutions that improve infants' health. It is essential that nurses continue to support these evidence-based models of care.

Case Study

Homelessness: Homeless Minority Infants

As a community health nurse in an inner-city health center, you are increasingly aware that the homeless population in your city appears to be the forgotten aggregate. Your community health center provides primary care to a culturally diverse and indigent population. As a nurse, you believe that the homeless population within your city has numerous health needs. Beyond the basic requirements, many homeless people have mental and substance abuse problems, a deficiency in life skills, and poor family support, and most of all lack access to child health services.

The homeless population has all the usual health problems you would expect in the general population in addition to other problems resulting from their homeless lifestyle. Although there are several glaring concerns, you plan to focus your attention first on securing immunizations for the homeless infants and, second, to obtain formula for them.

Reflective Questions

- In planning health services for this special population, what facts do you need to know?
- What barriers to accessing health care for minority infants confront the homeless family?
- How can you overcome some of the barriers in developing your plan for health care?

Discussion

- In planning health services for this special population, what facts do you need to know? The following are some of the first questions that should be asked:
- How many homeless minority infants are in this aggregate?

- Where are they?
- How can they access health care in the city?

To answer these questions, it might be prudent to collaborate and partner with other health and social service agencies, local hospitals, and the state health and human services agency. Collaboration and partnering can bring in additional resources and reduce duplication and gaps in services.

- What barriers to accessing health care for infants confront the homeless family?
- Lack of transportation
- Lack of trust in the medical establishment
- Judgmental care on the part of health care providers and nurses
- No health insurance to cover medical visits
- Preventive care, such as immunizations, not a priority when you are hungry
- No money to get prescriptions filled or transportation to get there
- Waiting until the condition is serious before seeking treatment
- How can you overcome some of the barriers in developing your plan for health care?
- Provide health care in the city shelters for use by homeless minority families.
- Set up a mobile health care team and visit the shelters to provide care.
- Offer free immunizations for all family members.

- Establish educational sessions within the shelters to provide information.
- Stress the importance of preventive measures to reduce illness in infants.
- Obtain free formula from companies or hospitals to give to homeless infants.
- Work closely with other health care interests within the community.

Care Plan

Homelessness: Homeless Minority Infants

Homelessness is a community dilemma and an example of an economic problem that places infants at risk. Families are the fastest growing group of homeless people. Homeless families do not have health insurance; infants within these families are more likely to lack immunizations, proper nutrition, a safe environment, and a stable family situation. The community health nurse in this chapter's case study wants to address two aspects of homeless infants: immunizations and nutrition.

*__NURSING DIAGNOSIS: Ineffective health maintenance related to nonadherence to appropriate immunization schedule as manifested by increased incidence of communicable diseases__

Defining Characteristics

- History of lack of health-seeking behavior by caregiver
- Lack of financial or other resources
- Reported or observed impairment of personal support systems
- Lack of knowledge regarding health-promotion practices

- Inability to access health care
- Limited basic personal resources

Related Factors

- Ineffective family coping
- Perceptual-cognitive impairment
- Lack of material resources
- Ineffective individual coping

Expected Outcomes

Caretaker of infant will:

- Begin health-seeking behavior on behalf of the minority infant.
- Increase health-promotion and health-maintenance knowledge.
- Gain access to available health care resources.
- Participate in life change to improve health status; meet goals for health care maintenance.

Nursing Interventions

- Assess caretaker's feelings, values, and personal situation.
- Assess the family for family patterns, economic issues, and cultural patterns that influence adherence.
- Assist the caretaker and minority family to access health care resources available to them.
- Refer the caretaker and family to community agencies to address

social and economic issues.

- Educate the caretaker and family on the importance of immunizations and disease prevention.
- Provide follow-up care to increase the chance of health status change occurring.

***NURSING DIAGNOSIS: Risk of imbalanced nutrition—less than body requirement related factors and socioeconomic factors as manifested by low height and weight measurements for chronological age on growth chart**

Defining Characteristics

- Pale conjunctival and mucous membranes
- Poor muscle development
- Inadequate food intake to maintain body weight
- Weight loss, fatigue, frequent irritable, fussy, crying behavior
- Growth and development milestones not met
- Frequent illnesses suggesting depressed immunity

Related Factors

- Inability to obtain adequate food or fluid or both to nourish body because of socioeconomic factors

Expected Outcomes

Infant will demonstrate the following:

- Progressive weight gains toward desired goal

- Weight within normal range for height and weight
- Minority infant consuming adequate nourishment
- Free of signs of malnutrition

Nursing Interventions

- Assess healthy body weight for age and height.
- Observe minority infant's ability to consume food and fluids.
- Monitor food and fluid intake weekly.
- Access nutritional resources for the caretaker or family.
- Refer family to appropriate community agencies to meet needs.
- Assist the caretaker or family to identify area needing change that will make the greatest contribution to improve nutrition.
- Implement instructional dialogue that is appropriate for their level.
- Provide follow-up care to assist them in changing their health status.

*NANDA Nursing Diagnoses—Herdman T. H., & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Never before has health promotion been more important than it is today. Nurses must have evidence-based understanding of the significant effect that can be made through health-promotion interventions and communicate this understanding to families they care for. Society is changing, as are people's needs and ideas. Families today want more information and knowledge, and they demand that health care professionals be more responsive to their needs. Their demand has been a catalyst for the nurse's expanded health care role and responsibility for health promotion. Nurses have been "touted" as potential major contributors to society's health promotion and illness prevention. Nurses are in the forefront of the health-promotion movement through their practice. Health promotion by nurses is associated with common universal principles of health education. Nurses should be able to plan, implement, and evaluate health-promotion interventions for infants and their families to improve their health outcomes.

Health-promotion and disease-prevention practices that are applicable during infancy can be used in the nurse's expanded role. A four-pronged approach is stressed:

- Giving anticipatory guidance to the family unit as the infant grows and develops
- Teaching and counseling to ensure the infant's optimal development
- Being a family advocate to ensure the safety and development of the family unit
- Screening infants to identify infants at risk of developing a condition via history gathering, physical examination, observation of parent-child interaction, and laboratory testing

Anticipating potential health problems during infancy and effectively intervening to avert these problems are nursing processes that promote health. Early detection and reduction of risk factors avoid many health problems, such as abuse. By anticipating problems

and helping families to avoid them, the nurse promotes health maintenance.

Using the infant's normal growth and development, psychosocial tasks, common health problems, and health maintenance strategies, the nurse assesses the infant, the family, and the infant's developmental status to provide anticipatory guidance.

By teaching (Box 17-18: Genomics), an essential component of the nursing process, the nurse transmits knowledge to families to ensure continuity of care and long-term health maintenance. By counseling, the nurse listens to the identified problem, helps the family to recognize the real issues, and allows the family to make its own decisions regarding health care.

Box 17-18

Genomics

Genomic sequencing can identify genetically based conditions that routine blood tests used to screen every newborn baby cannot detect. The standard newborn screening blood tests look for chemical changes and typically screen newborns for a few dozen disorders, such as sickle cell anemia and cystic fibrosis, that are caused by a gene mutation. But researchers have tallied more than 6000 such inherited disorders caused by a single mutated gene. And other genes are associated with higher risks of certain conditions, such as heart disease. Imagine being able to anticipate a child's health all the way to adulthood.

In the next few decades, every infant's genome can be sequenced and used to shape a lifetime of personalized strategies for disease prevention, detection, and treatment.

But this brave new world is fraught with technical and ethical issues that have some scientists questioning whether every infant should have its genome sequenced and what information children and parents should receive about the results.

Every individual's genome is loaded with “variant” genes, and harmful mutations make up just a small fraction of them. Researchers

have only begun to catalog which variants cause problems. Questions arise about the wisdom of telling parents and children about conditions for which there is no effective treatment or of letting them know about disorders that will not affect a child until adulthood. Families will need to decide this as this latest technology moves forward.

From Bavley, A. (2016). Genome sequencing hold tremendous promise for infants, but issues abound. *The Kansas City Star*. http://www.kansascity.com/news/business/health-care/article21973176.html; National Human Genome Research Institute. (2016). Newborn screening. https://www.genome.gov/27556918.

Because the infant is in no position to advocate for itself effectively, the nurse assumes the role of advocate. The ultimate goal of nursing intervention in maintaining the infant's health is future self-care. As the infant grows and matures, well-established family health maintenance habits can only enhance the lives of healthy future generations. The nurse is challenged to join this effort of investment in the future.

Toddler

Diane Marie Welsh

OBJECTIVES

After completing this chapter, the reader will be able to:

- Describe the physical growth, developmental, and maturational changes that occur during the toddler period.
- Examine the recommended health-promotion and disease-prevention visits for the toddler with the appropriate topics for anticipatory guidance for the parents.
- Compare and contrast developmentally appropriate approaches to toddlers at different ages.
- Analyze the factors that contribute to the heightened vulnerability of toddlers to injury and abuse.
- Develop a plan to reach the *Healthy People 2020* target objectives specific for toddlers.

KEY TERMS

Amblyopia

Autism spectrum disorders

Autonomy

CDC growth charts

Child abuse

Conditioned-play audiometry

Doubt
Egocentrism
Lumbar lordosis
Masturbation
Night terrors
Object permanence
Otitis media
Parallel play
Preoperational stage
Rituals
Sensorimotor stage
Shame
Strabismus
Styes
Temperament
Toilet training
Visual-reinforcement audiometry
World Health Organization growth charts

Think About It

Refraining the Terrible Twos

A young mother tells the nurse that she is convinced her 22-month-old child, who used to be the sweetest child around, has entered what must be the terrible twos. She reports that her child's favorite words include "mine" and "no," with "no" being the response to every request the mother makes. In addition, the child is becoming increasingly stubborn and just threw her first public temper tantrum. The mother says that she is tired of saying and hearing "no" and turns to the nurse for help.

- How does the nurse explain the relationship between the child's stage of psychosocial development and meaning behind the child's behaviors?

- What suggestions can the nurse give the mother to respond sensitively to her child's evolving need for independence while balancing her own need to provide for and protect her child?

Having spent their first year of life getting to know and trust their parents and other child care providers and their immediate environments, toddlers' increasing mobility now allows them to begin to expand their worlds, bringing excitement and challenges to both themselves and their parents. Toddlers are ready to develop a sense of self and separate from their parents, and understanding and respecting this evolving independence is a common parental challenge. Their behaviors can be frustrating, but the toddlers' delight in their own emerging competence and achievements can bring a sense of joy and accomplishment to everyone around them (Kochanska et al., 2013).

Nurses explain to parents and other primary care providers the many physical and developmental changes that occur in toddlers and describe how these changes contribute to their vulnerability to injury and overall health, as well as to the health and vulnerability of the family unit (CDC, 2015d). Unfortunately, the recommended schedule for health-promotion and disease-prevention visits for this age group advocates fewer contacts than during infancy. Parents may begin to fall into a pattern of illness care, missing the continued opportunity to receive anticipatory guidance and health-promotion information until they are required by preschool or school prerequisites. The nurse plays an integral role in encouraging health-promotion efforts and behaviors (Hockenberry & Wilson, 2015; Spence et al., 2013).

Biology and Genetics

The toddler period begins at 12 to 18 months and extends to 3 years of age. The overall growth rate slows significantly, and the increasingly active toddler begins the process of shedding baby fat and straightening his or her posture. Toddlers have a protuberant abdomen, accentuated by a **lumbar lordosis**, and a characteristic gait, in which their feet are planted wide apart and appear flat because of an extra fat pad in the instep for stability.

A slow, steady growth in height of 2 to 4 inches per year and in weight of 4 to 6 pounds per year occurs during toddlerhood, and growth remains steady until puberty. Birth weight usually quadruples by $2\frac{1}{2}$ years of age, and the toddler's height at age 2 years is approximately 50% of the final adult height (Hockenberry & Wilson, 2015). Growth charts are used to determine the parameters within which an individual toddler's growth lies for head circumference, height, and weight. The Centers for Disease Control and Prevention (CDC) recommends that health care providers use the 2006 **World Health Organization growth charts** to monitor growth for infants and children up to 2 years of age in the United States, and then use the 2000 revised **CDC growth charts** for US children aged 2 to 20 years (CDC, 2010; Grummer-Strawn et al., 2010). The toddler's height may be measured with the toddler in a recumbent position for length, as in infancy, or in a standing position for stature. When the CDC growth charts for toddlers aged 2 years or older are being used, measure the height with the toddler in a standing position to obtain the toddler's stature and then use the appropriate chart based on stature.

The nurse continues to measure head circumference throughout the toddler period. The anterior fontanel usually closes by 18 months, the skull begins to thicken, and by 24 months it is 80% of its adult size (Hockenberry & Wilson, 2015).

The kidneys are well differentiated by the toddler years, and specific gravity and other urine findings are similar to those of adults. The daily excretion of urine for the 2-year-old child is 500 to 600 mL,

increasing to 750 mL for the 3-year-old. Toddlers empty their bladders less frequently than infants and begin to develop voluntary control of urination. However, full bladder control comes later and begins after 18 to 24 months, when the toddler first becomes physiologically able to control the bladder.

The toddler's gastrointestinal tract also reaches functional maturity, although it continues to grow into adulthood. The toddler tends to need meals and snacks more frequently than an older child or adult. Most toddlers develop sufficient voluntary control of internal and external anal sphincters to accomplish successful bowel training. Bowel control usually occurs before urinary control.

Lung capacity continues to increase as the toddler grows, and the respiratory rate decreases from a mean of 30 breaths per minute at 1 year of age to 25 breaths per minute at 3 years. The diameter of the toddler's upper respiratory tract is small compared with that of an older child or adult, and this may lead to mouth breathing when the nose is obstructed with mucus (Figure 18-1). This small diameter, coupled with the toddler's exploratory nature and lack of judgment in deciding what to place in the mouth, can result in accidental airway obstruction, which demands emergency action.

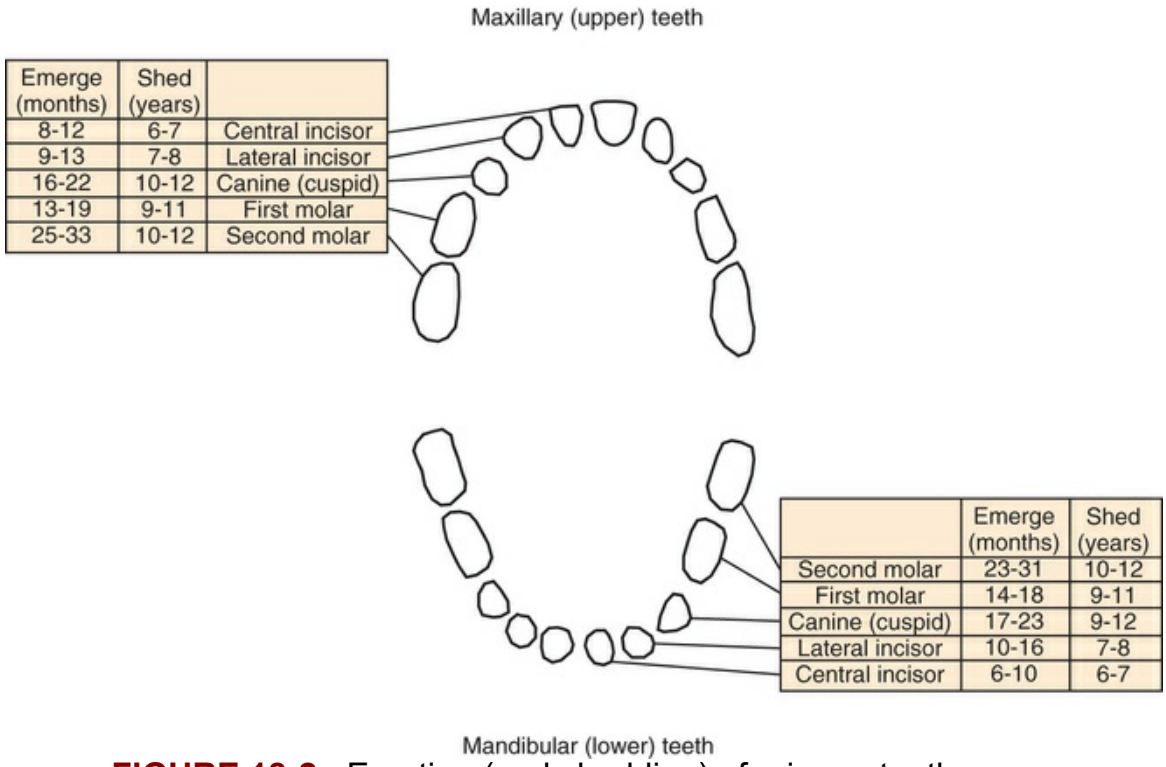
FIGURE 18-1 Toddler demonstrates mouth breathing.

The proximal anatomy of the ear, eustachian tube, and nasal pharynx continue to resemble those of the infant more closely than those of the adult, continuing the risk of otitis media. The tonsils and adenoids remain proportionately large during the toddler years (Seidel et al., 2011).

With the exception of reproductive functions, most endocrine organs become functionally mature during the toddler and preschool years, although function continues at a minimum. The production of glucagon and insulin can be limited or labile, producing variations in blood glucose levels throughout early childhood. The production of cortisol, aldosterone, and deoxycorticosterone by the adrenal cortex remains somewhat limited, but they appear to function effectively in protecting the young child from the hazards of fluid and electrolyte

imbalance well known in infancy. Secretion of epinephrine and norepinephrine from the adrenal medulla increases sufficiently to perform homeostatic functions of the autonomic nervous system and to mediate certain aspects of increased emotional components of behavior. Regulation of growth during early childhood remains one of the most important functions of the endocrine system.

Changes in the circulatory system include a decrease in heart rate, an increase in blood pressure, and a change in vascular resistance in response to growth in the size of various blood vessel lumens. The toddler's heart rate ranges from 80 to 120 beats per minute, and the mean blood pressure is 90/56 mmHg. Getting the toddler to sit still for a blood pressure reading can be difficult, but it is worth the effort to obtain several baseline readings for future reference.



The capillary beds gradually increase their capacity to respond to heat and cold in the environment, providing the toddler with more effective thermoregulation. Toddlers can also begin to take voluntary measures to relieve the discomfort of heat or cold. For example, the older toddler can put on clothing or move to warmer or cooler areas, assisting physiological efforts to maintain a constant internal thermal environment.

The immune response continues to mature. As toddlers expand their worlds through play groups and day care centers, exposure to new and different organisms is greatly increased. They may experience a period during which they appear to succumb to many minor respiratory tract and gastrointestinal tract infections. As immunity begins to develop against the organisms in their new environments, their resistance similarly increases.

Passive immunity to communicable disease acquired through transfer of maternal antibodies during fetal life has disappeared, and active immunity through the initial immunization series is usually completed by the age of 18 months. The next scheduled immunizations do not occur until age 4 to 6 years, before the toddler enters kindergarten. If a toddler is behind in the initial immunization series, a separate schedule is available that gives catch-up schedules and minimal intervals between doses (CDC, 2015a). For updated CDC

immunization schedules and the latest guidance refer to the CDC website at http://www.cdc.gov/vaccines/schedules/.

All 20 primary or deciduous teeth erupt by the end of toddlerhood (Figure 18-2). The timing of these eruptions can differ widely, but a variation in the sequence alerts the nurse to inquire about early trauma to the mouth or familial traits for nonsequential tooth eruption. Application of fluoride varnish to primary teeth is recommended shortly after the teeth erupt through the gum. Important aspects of dental care at this age are included in health teaching and are listed in Box 18-1.

Emerge (months)	Shed (years)	
8-12	6-7	Central incisor
9-13	7-8	Lateral incisor
16-22	10-12	Canine (cuspid)
13-19	9-11	First molar
25-33	10-12	Second molar

	Emerge (months)	Shed (years)
Second molar	23-31	10-12
First molar	14-18	9-11
Canine (cuspid)	17-23	9-12
Lateral incisor	10-16	7-8
Central incisor	6-10	6-7

FIGURE 18-2 Eruption (and shedding) of primary teeth.

Box 18-1

Nursing Interventions to Promote Dental Health Care for Toddlers

Brushing

- When teeth are present, begin to use a soft-bristled brush. The finger-wrapped gauze method used during infancy is no longer adequate because the teeth are too close together to reach all tooth surfaces.

- Introduce only a moist toothbrush at first. After the toddler has accepted the toothbrush, begin using toothpaste. A pea-sized amount is adequate. If the child does not like the taste of the toothpaste, use plain water.

- Toothpaste should contain supplemental fluoride if not in water supply. The US Preventive Services Task Force recommends that primary care clinicians prescribe oral fluoride supplementation starting at age 6 months if the water supply is not fluoridated.

- Toddlers do not have the motor coordination to brush their own teeth. They may enjoy imitating parents and put the toothbrush in their mouths, but an adult should be responsible for the actual brushing.

- Brush daily; for many toddlers, this practice becomes part of the bedtime routine. When the child appears too tired to cooperate in the evening, the parent should choose some other time of day when this important task will not be so difficult.

Foods

- Limit intake of foods high in sugar because they contribute to dental caries.

- When the young toddler still drinks from a bottle, only plain water should be given. Milk and juices should be offered by cup. If milk or juice is given in a bottle, this should never be done at naptime or bedtime.

Visits to the Dentist

- The first visit to the dentist should occur during the toddler years. Many dentists suggest an introduction-orientation, inspection-consultation type of visit when the child is approximately 18 to 24 months of age. This type of visit provides an early, enjoyable introduction to professional dental health promotion and care.

- Once the primary teeth of infants and children have erupted, the US Preventive Services Task Force recommends the application of fluoride varnish to the primary teeth.

From US Preventive Services Task Force. (2015). Dental caries in children from birth through age 5 years. http://www.uspreventiveservicestaskforce.org.

A mature swallowing pattern, using the tongue rather than the cheeks, has not yet developed, and toddlers continue to be at risk of choking. Toddlers who are mouth, rather than nose, breathers because of ongoing respiratory illness or allergies may have an underdeveloped palatal arch. With normal breathing, the tongue rests on and naturally widens the palate; however, when the child is forced to breathe through the mouth, the tongue rests in the lower jaw, not on the palate. This resultant narrowing of the palatal arch predisposes these toddlers to dental crowding when the permanent teeth erupt (Guilleminault et al., 2015).

An increase in the size and strength of muscle fibers continues. During this period, as during infancy, the use of muscle tissues is the primary stimulus for increased size and strength for gross and later fine motor movement. Myelination of the corticospinal tract is functionally sufficient to support most movement, but achievement of full control does not occur until much later in life. Throughout early childhood, voluntary motor movement is often accompanied by involuntary movements on the opposite side of the body. This mirroring of action is more pronounced in children who have some damage to the central nervous system, but the mechanisms by which this occurs are unknown. The toddler generally does not show

complete dominance of one side of the body and may still switch hands when eating, throwing a ball, or engaging in other-handed activities.

Genes are passed from each parent to the child, and great similarities may show between the generations. Most genetic syndromes and disease entities are diagnosed either during the prenatal period or during infancy. However, some genetic syndromes and diseases are not detected until the toddler years or even later. The most common initial sign is a change in growth pattern or developmental delays (Box 18-2: Genomics).

Box 18-2

Genomics

Celiac Disease

- Immune-mediated disorder that affects those with genetic susceptibility to it. When gluten (a protein found in wheat, barley, and rye) is consumed, the individual gets sick.
- Symptoms include gastrointestinal complications such as constipation, cramping, nausea and vomiting, diarrhea, and weight loss. Nutritional deficiencies may result.
- Affects 0.6% to 1.0% of the population worldwide, with prevalence differing regionally for unknown reasons.
- Certain genes are seen in individuals with celiac disease. Although not causal, it appears that *HLA-DQ2* and *HLA-DQ8* haplotypes are largely expressed in individuals with celiac disease.
- For disease diagnosis, serological testing of antibodies IgA and IgE is performed. Further testing involves biopsies of the intestines, which measures expression of haplotypes *HLA-DQ2* and *HLA-DQ3*.

- Treatment for children with celiac disease is a completely gluten-free diet. As a result of the recent increased awareness around gluten allergies, there are more gluten-free food choices available at the grocery store.

For more information on celiac disease, visit http://www.celiac.org.

Developmental delays are often not diagnosed during infancy because the subtle language, motor, or cognitive deficiencies do not interfere with the expected performance and behavior of the infant as they do with those of the more actively developing toddler.

Gordon's Functional Health Patterns

Health Perception–Health Management Pattern

Toddlers may eventually learn that being sick means feeling bad or having to stay in bed, but they have little, if any, understanding of the meaning of health. They may perform requested health-promotion activities, such as brushing teeth, but they may simply brush their teeth as part of their bedtime ritual and not because they know this activity will prevent dental caries. Toddlers depend on their parents for health management, and their overall health will be greatly influenced by their parents' health perceptions and health-management priorities (Box 18-3: *Healthy People 2020*).

Box 18-3

Healthy People 2020

Selected Health-Promotion and Disease-Prevention Objectives for Toddlers

- Increase age-appropriate vehicle restraint system use in children aged 1 to 3 years to 79% from the baseline of 72% for children aged 1 to 3 years restrained in front-facing child safety seats in 2008.
- Reduce death among children from child maltreatment for those younger than 18 years from 2.3 deaths per 100,000 children in 2008 to 2.1 deaths per 100,000 children; and reduce unintentional suffocation deaths among infants aged 0 to 12 months from 23.1 deaths per 100,000 infants in 2008 to 20.8 deaths per 100,000 infants.
- Reduce iron deficiency among young children aged 1 to 2 years from 15.9% in 2005 to 2008 to 14.3%, and in children aged 3 to 4 years from 5.3% in 2005 to 2008 to 4.3%.

- Reduce blood lead levels in children aged 1 to 5 years (baseline was 2.5% of children aged 1–5 years had blood lead level of 5.8 mcg/dL in 2005 to 2008, goal is 5.2 mcg/dL by 2020).

- Reduce exposure to selected environmental toxins as measured by blood and urine concentrations of the substances or their metabolites in children aged 1 year or older in 2003 to 2004, especially reduce cadmium, mercury, and lead levels.

- Reduce outpatient visits for ear infections where antibiotics were prescribed to young children, especially for ear infections in those younger than 5 years from 77.8% in 2006 to 2007 to 70%.

- Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children aged 19 to 35 months, especially increase the level of four doses of diphtheria, tetanus, and acellular pertussis vaccine from 85% in 2008 to 90%; the level of three doses of *Haemophilus influenzae* type b conjugate vaccine from 57% in 2008 to 90%; the level of four doses of pneumococcal conjugate vaccine from 80% in 2008 to 90%; the level of two doses of hepatitis A vaccine from 40% in 2008 to 60%; the level of a birth dose of hepatitis B vaccine from 51% in 2006 and 2008 to 85%; the level of two or more doses of rotavirus vaccine from 38% in 2009 to 80%.

- Increase the proportion of children aged 19 to 35 months who receive the recommended doses of diphtheria, tetanus, and acellular pertussis vaccine, polio vaccine, MMR vaccine, *Haemophilus influenzae* type b conjugate vaccine, hepatitis B vaccine, varicella vaccine, and pneumococcal conjugate vaccine from 68% in 2008 to 80%.

- Reduce invasive pneumococcal infections among children younger than 5 years: reduce new invasive pneumococcal infections from 20.3 cases per 100,000 in 2008 to 12 cases per 100,000; reduce invasive penicillin-resistant pneumococcal infections from 4.3 cases

per 100,000 in 2008 to 3 cases per 100,000.

- Increase the proportion of young children screened for an autism spectrum disorder and other developmental delays by 35 months of age from the 2007 baseline of 22.6% of children aged 10 to 36 months to 24.9%.

- Increase the proportion of newborns who are screened for hearing loss by no later than age 1 month from 82% in 2007 to 90.2% in 2020.

- Increase the proportion of newborns who receive audiological evaluation no later than age 3 months for infants who did not pass the hearing screening from 66% in 2007 to 72.6%.

- Increase the proportion of infants with confirmed hearing loss who are enrolled for intervention services no later than age 6 months from the 50% in 2007 rate to 55%.

- Increase the proportion of preschool children aged 5 years or younger who receive vision screening from 40.1% in 2008 to 44.1%

(2010). Healthy People 2020: Midcourse review. http://odphp.osophs.dhhs.gov/pubs/.

Toddlers identify with parents, caregivers, and other important role models, internalizing a wide range of lifestyle attributes. Parents' and caregivers' health perceptions and health behaviors should model the perceptions and behaviors desired for health promotion. Toddlers whose parents eat a variety of foods are more likely to try new foods. Such modeling increases the chances that good practices will be retained throughout the toddler's life. The nurse's task is to help parents strengthen their confidence and self-esteem as parents and

provide them with the information needed to anticipate and meet the developmental needs of their toddler as they develop as a family.

Nutritional-Metabolic Pattern

The American Academy of Pediatrics (AAP, 2012) recommends breastfeeding for 1 year or longer as preferred between a mother and a child. Adequate iron intake must be ensured as the toddler changes from breast milk or iron-fortified formula and cereal to whole cow's milk, which is low in iron. Whole cow's milk also interferes with the absorption of iron from other food sources. A toddler who continues to ingest whole milk from a bottle tends to drink up to 32 ounces per day. This practice blunts the child's appetite at mealtimes and can lead to an exclusion of foods that contain iron in the diet (AAP, Healthy Children, 2012), requiring iron from fortified foods or supplements. The use of a bottle with milk or juice, especially at bedtime, has also been associated with dental caries (baby bottle tooth decay) because of the high sugar content. If parents want to give a bottle at bedtime, it should contain only water.

Fruit juice and other drinks are often overconsumed because they taste good, because they are conveniently packaged and easily carried around by the toddler, and because they are viewed as nutritious. However, the AAP, Healthy Children (2012) cautions parents to use only 100% juice that is pasteurized, that children aged 1 to 6 years have two fruit servings each day, only one of which should be juice, and that consumption of fresh fruit should be encouraged. It further states that 4 to 6 ounces (120 to 180 mL) of fruit juice equals one fruit serving. Fruit juice has no nutritional advantage over whole fruit and in fact lacks the fiber contained in whole fruit (AAP, Healthy Children, 2012, 2015).

A decrease in the growth rate during toddlerhood results in a decrease in appetite. Parents need to be reminded of this if they begin to worry about their toddler's nutritional intake (AAP, 2011). A daily record kept over a 3- to 5-day period presents a better picture of a child's intake and is a useful teaching tool for this age group.

Toddlers often use mealtime as an occasion to assert individuality

and control as well as exploration. Families will differ in their expectations of eating behavior and mealtime routines. The nurse's best guide for parents of toddlers is to remind them that parents are in charge of what food is offered, when it is offered, and where it is offered (Box 18-4: Research for Evidence-Based Practice). Box 18-5 lists some nursing interventions to promote healthy eating in toddlers. However, it is up to the toddler to decide the amount to actually eat. Periodically, a toddler may even refuse a meal altogether. Parents need to be encouraged to offer healthy, age-appropriate food choices (Figure 18-3). Toddlers will eat them, as long as they do not fill up on empty calories from juice and high-carbohydrate snacks that are often given to children "so they eat something." Furthermore, parents should not focus too much attention on food intake or punish children for refusing food. Toddlers may learn how easily parents can be controlled by their behavior around food intake and may then continue the behavior for the attention alone.

Box 18-4

Research for Evidence-Based Practice

Asthma, Diet, and Toddlers—A Cure?

The toddler diet is a force with which to be reckoned because the toddler has tastes for nonnutritious and highly sweetened food. Imagine that same toddler with asthma or wheezes and that the possibility of following a Mediterranean diet might eliminate asthma symptoms. Three different meta-analyses were conducted: one meta-analysis investigated dietary effect on those with current wheeze; the second meta-analysis investigated dietary effect on current severe wheezes; and the third meta-analysis investigated dietary effect on those with a diagnosis of asthma but not currently experiencing symptoms.

The meta-analysis investigating dietary exclusions included seven randomized controlled trials. Participants who consumed a Mediterranean diet consumed foods low in saturated fatty acids, rich

in carbohydrates, fiber, and antioxidants, with a high content of monounsaturated fatty acids and *n*-3 polyunsaturated fatty acids. There was a benefit of this diet for those with current wheezes and those with diagnosed asthma; however, there did not appear to be a benefit for those with current severe wheezes. The researchers note that the Mediterranean diet might be beneficial in asthma development because it might have the ability to counteract oxidative stress that occurs in the respiratory tract.

The hierarchical strength from this study is as powerful as possible for a study with randomization of the sample participants and the treatment modality, and the use of a control group. However, limits always occur with meta-analyses because of the various methods used within the studies. So even with randomized controlled trials, one must be cautious when interpreting the evidence.

Box 18-5

Nursing Interventions to Promote Healthy Eating in Toddlers

- Routines are important to toddlers. Serve scheduled meals and snacks. Parents are responsible for what, when, and where the toddler eats. The toddler decides whether to eat and how much.
- Schedule meals and sleep periods such that the child is awake and alert during mealtime.
- Turn off the television. Mealtime should be a relaxed and pleasant time, free of distractions.
- Serve small portions and let your toddler ask for more.
- Offer simple, single foods, because mixtures of foods are often

rejected.

- Serve your toddler's favorite foods along with new ones. Several introductions may be necessary before the toddler accepts a new food. Make sure you eat it too.
- Encourage the use of utensils, but accept that toddlers still often need to use their fingers.
- Do not use food to bribe, reward, or punish your toddler.
- Avoid foods that may cause choking, such as hard candy, mini marshmallows, popcorn, pretzels, chips, and spoonfuls of peanut butter, nuts, and seeds, large chunks of meat, hot dogs, raw carrots, dried fruits, and whole grapes.
- Drinking more than 24 ounces of milk per day can reduce your child's appetite for other healthy foods. For those younger than 2 years, do not use reduced-fat, low-fat, or fat-free (skim) milk because children younger than 2 years need the extra fat for their developing nervous systems.

FIGURE 18-3 Toddlers need healthy, age-appropriate food choices.

Maintaining a record of food intake over time, the nurse can demonstrate the adequacy of the nutrients that the toddler is already receiving during mealtimes and help parents develop a plan to offer more of the essential foods during meals (Holt et al., 2011). Children with inadequate nutrition are predisposed to impaired immune systems, leading to infections and delayed healing and recovery. They are also predisposed to depletion of muscle mass, leading to diminished functional capacity. In addition, although inadequately understood, nutrients and neurotropic factors interact with one another for brain and behavioral development (Ruel & Alderman, 2013).

The family who has a vegetarian or vegan diet may need some assistance from the nurse or a dietitian. Vegetarian and vegan diets differ widely, so it is important to assess precisely the foods that are eaten, the foods that have been eliminated from the diet, and the supplements that are used.

Elimination Pattern

Toilet training is often a major parental concern during toddlerhood. The nurse anticipates this developmental stressor and initiates discussion with the parents to determine their understanding of the child's signs of developmental readiness and their attitude and commitment to establishing a toileting pattern for their toddler. Emotional and physiological readiness for toilet training rarely develops before 18 months of age. Parents who begin before their child is ready usually experience frustration.

Nursing Interventions

By suggesting the sequence in Box 18-6: Nursing Interventions, the nurse assists parents with toilet training. The parent who can approach toilet training with a relaxed attitude, accepting some delays and frustrations, will have a better chance of success and a more positive outcome for the toddler.

Box 18-6

Nursing Interventions

Initiating a Toileting Program for Toddlers

Interest in and awareness of bowel and urinary elimination usually begin by 18 months of age.

- Before beginning toilet training, parents should check their toddlers for the prerequisite skills, which include being able to walk well, stoop and recover, stay dry for at least 2 hours during the day, and communicate sensation before elimination, as well as the discomfort of wet or messy pants and the need for assistance.

- When these prerequisites are present, introduce the child to a potty seat or chair. The potty chair should provide secure seating with the child's feet touching the floor. The potty seat should be used with a small step stool to create the same effect.

- Because of the gastrocolic reflex, bowel elimination is more likely after a meal, so this is a good time to place the toddler on the potty. When a pattern of bowel or urinary elimination is noticed, use this pattern as a guide for placing the child on the potty.

- Encourage the toddler to stay on the chair for 2 to 3 minutes and always explain what to do ("Go potty") rather than what not to do ("Don't wet your pants"). Do not refer to elimination as dirty or yucky. Remember this is your child's first creation.

- Praise the child for desired behavior. Introduce underwear as a badge of success. Ignore undesired behavior and never punish the child by scolding the child, spanking the child, or other punitive measures.

Remember that daytime dryness is usually achieved by 3 years of age and ahead of nighttime dryness, where the need to wear a diaper remains.

Activity-Exercise Pattern

Toddlers are always busy—emptying wastebaskets and drawers, building and destroying towers, throwing, kicking, and chasing after balls, or dressing and undressing. Many of their activities are repeated over and over, providing practice opportunities for their newly realized skills. The various toys designed for toddlers capitalize on this ability to explore and imagine with laptop trainers, electronic coloring tablets, musical instruments, and books with accompanying audiovisual disks.

During the toddler period, children will advance from taking their first step to running, climbing stairs, and even pedaling a tricycle. They enjoy pushing and pulling, whether it is an unsuspecting laundry basket or a push-pull toy made for the job. They scribble spontaneously, usually with vigor, and will emerge from toddlerhood capable of copying a circle and creating tadpole-like figures. They learn to use a spoon and a fork with fairly good success and to wash

their hands. They also advance from being dressed by others to dressing themselves with assistance, although at times they resist it.

Toddlers spend most of their waking hours at play—exploring their expanding environment, imitating others' actions, and creating a safety net of **rituals** around the routines of eating, sleeping, and everything in between. In their enthusiasm to try many activities, toddlers invariably take on tasks that are beyond their abilities, which can result in frustration and an occasional well-known temper tantrum. Their exploratory nature and limited, but advancing, skills also make them vulnerable to injury.

Most toddlers are interested in other children. However, this interest is limited because toddlers, although ready to be with other children, are not ready to share. Successful social encounters with toddlers are best described as **parallel play,** where children play side by side, doing similar things with similar toys, but each working independently (Berger, 2011). Sharing and cooperative play will not develop until well into the preschool age.

Nursing Interventions

When parents inquire about what toys and activities to provide for their toddler, the following are suggested:

- Provide toys that challenge the child to develop new skills: toys that require skills slightly above the child's present level, but not so advanced that the child cannot achieve some success.
- Provide opportunities for new learning. This may be as basic as a book with pictures of new animals or a walk through the produce section of the grocery store to point out fruits and vegetables.
- Provide opportunities for social encounters with other children, but do not force playing together. Creating separate yet parallel space, with the use of small mats or hula hoops as boundaries, is recommended.
- Follow the child's lead. Let the toddler choose and explore new toys or objects, within safe limits.
- Make sure the toy is safe for the toddler and does not have any parts

that can be removed and swallowed, have lead paint, or can cause harm to the curious toddler.

The desire of some parents to raise the smartest, most coordinated, or most musically talented super kids often begins in the toddler period. It is interaction with parents and others in their environment that provides the advantage with cognitive development. The AAP (2013a) recommends no screen time, including television, videos, tablets (iPads), and computers, for children younger than 2 years. For older toddlers, the AAP recommends no more than 1 to 2 hours daily of high-quality screen time with the parent watching too. For interactive computer games that may include touch screens (on smartphones and tablets), the parent needs to be there with the toddler so that two-way conversation occurs. Ideally, children should be allowed to explore their interests, with parents responding to their cues. Past research associated television watching by toddlers with interference at a critical time when language development occurs and suggested that this can cause a delay in that process. Current research indicates that audible television loud enough to decrease the child's exposure to discernible adult speech and decreased child vocalizations also lead to delayed speech development (Pempek et al., 2014). Additionally, the more television shows with advertising watched, the more likely the child will become obese (Zimmerman & Bell, 2010). For more information on helping parents support their toddler's activity, use of technology, and exploration in a safe and educational way, visit the Zero to Three website at http://www.zerotothree.org.

Sleep-Rest Pattern

Toddlers' need for sleep decreases to 12 hours a day, including one or two naps of shorter duration. One of the naps is usually replaced by quiet time, a brief period to unwind from a busy or noisy activity. Occasionally the parents or caregivers need these rest breaks as much as or more than the toddler. Sitting together in a rocking chair for a soothing song or quiet music or reading side by side or together can be suggested by the nurse.

The toddler may be involved in an activity and not be aware of fatigue, especially when visitors are in the home or some interesting new toys have been discovered. All parents are familiar with the child who is overtired but unable to relax enough to sleep. Parents can potentially avoid this dilemma by scheduling nap and quiet time even when there are house guests or holidays that preempt the toddler's routine.

Rituals are characteristic of this age, and most toddlers have a nap and bedtime ritual. The following might be a typical pattern: eating a nutritious snack, followed by bathing, brushing teeth, listening to a story, getting a kiss, and having overhead lights turned off and the night light turned on. Following this ritual is important because the toddler gets a sense of security when ending the day. Changing this ritual can be upsetting. The nurse encourages parents to establish and follow the bedtime ritual as closely as possible, even when visitors, family illness, or travel makes the routine more difficult. In addition, incorporate rituals as much as possible when the toddler stays outside the home; for instance, staying overnight at their grandparent's house or during a hospitalization.

Many toddlers will try to delay sleep by calling for water, another story, or another kiss, or by making other requests. Parents should be certain that the toddler has ample opportunity for interaction with them during the day, follow the usual bedtime ritual, and be firm and consistent in resisting any requests for attention after the final good nights have been said. Encouraging toddlers to use transition or security objects, such as stuffed animals or blankets, helps them to self-quiet and console themselves both at bedtime and in new situations (Figure 18-4).

FIGURE 18-4 Toddlers need adequate sleep for healthy growth, and their stuffed toys can help them feel more secure.

Night terrors may begin in toddlerhood. Night terrors are different from nightmares, which generally begin at a later age and result in the child awakening and being able to recall the frightening dream. The child who experiences night terrors does not waken completely, but cries out, looks terrified, and cannot be aroused for several minutes. Eventually, usually after 5 to 10 minutes, the child falls back into quiet sleep. Parents need to be reassured that these episodes will become less frequent as the child develops. The parents should talk in a soothing voice but should not try to awaken the child. If the child does

waken, the parents should then provide comfort and tuck the child back in bed.

Cognitive-Perceptual Pattern

Toddlers who experienced the security of a nurturing and reliable source of protection and attachment during infancy have a strong base from which to begin to explore and learn about their expanding world. They begin toddlerhood in Piaget's **sensorimotor stage** of cognitive development and start moving to the **preoperational stage**. Their advancing thought-processing skills and abilities to use the language are heralded by the development of **egocentrism**, an inability to put oneself in another's shoes. Toddlers who come running into a room asking their parents "Where is it?" are confused when parents respond "Where is what?" They assume their parents and all others share their same thoughts and cannot understand why they do not.

Toddlers interpret and learn about objects and events, not in terms of general properties but in terms of their relationship with them or their use to them. Their thoughts are dominated by what they see, hear, or otherwise experience, and they want to experience everything. Their two- to three-word phrases are most often related to present events, describing an action, a desire, or a possession (e.g., "Mommy, me up!").

Both receptive and expressive language skills are developing rapidly in toddlers; however, their receptive language skills far outweigh their expressive language ability, and toddlers often use gestures until words are found to represent the meanings already acquired. Toddlers also learn the use of inflection. "Mommy" may mean "Pick me up" on one occasion and "I'm scared" or "Where are you?" on another. Often frustrated by their limited repertoire of expressive language, which usually includes approximately 400 words, young toddlers default to using "no" as a method of gaining control over a situation or expressing themselves (see the Think About It box at the beginning of this chapter).

By age 3 years, children have mastered the basics of language

function, form, and content, and these fundamentals will continue to be refined throughout childhood and adolescence. Table 18-1 outlines the landmarks of speech, language, and hearing ability for this age group.

TABLE 18-1

Growth and Development
Landmarks of Speech, Language, and Hearing Ability During the Toddler Period

Age (Months)	Receptive Language	Expressive Language	Related Hearing Ability
18	Up to 50 words; recognizes between 6 and 12 objects by name, such as *dog, cat, bottle, ball;* identifies three body parts, such as *eyes, nose, mouth;* understands simple, one-step commands such as *give me the doll, open your mouth, stick out your tongue*	Up to 20 words; jargon and echolalia are present; uses names of familiar objects and one-word sentences, such as *go* or *eat;* uses gestures; uses words such as *no, mine, eat, good, bad, hot, cold,* and expressions such as *oh-oh, what's that, all gone;* use of words can be quite inconsistent; 25% of speech intelligible	Has begun to develop gross discrimination by learning to distinguish between highly dissimilar noises, such as doorbell and train, barking dog and automobile horn, or mother's and father's voices
24	Up to 1200 words; knows *in, on, under;* identifies *dog, ball, engine, bed, doll, scissors, hair, mouth, feet, nose, cup, spoon, car, key;* distinguishes between one and many and formulates a negative judgment (a knife is not a fork); understands simple stories; follows simple, two-step directions; is beginning to make distinctions between *you* and *me*	Up to 270 words; jargon and echolalia almost gone; average 75 words per hour during free play; talks in words, phrases, and two-word to three-word sentences; averages two words per response; first pronouns appear, such as *I, me, mine, it, who, that;* adjectives and adverbs are only beginning to appear; names objects and common pictures; refers to self by name, such as *Katrina go bye-bye;* uses phrases such as *I want, go bye-bye, want cookie, ball all gone;* 60% of speech intelligible	Refinement of gross discriminative skills
30	Up to 2400 words; identifies action in pictures and objects by use; carries out one-part and two-part commands,	Uses up to 425 words; jargon and echolalia no longer exist; averages 140 words per hour; names words such as *chair, can, box, key, door;* repeats two digits from memory; average sentence length is approximately 2.5 words; uses more adjectives and	—

	such as *pick up your shoe and give it to mommy;* knows what is used to drink liquids, what goes on the feet, what is used to buy candy; understands plurals, questions, difference between boy and girl, the concepts *one, up, down, run, walk, throw, fast, more, my*	adverbs; demands repetition from others, such as *do it again;* nearly always announces intentions before actions; begins to ask questions of adults; 75% of speech intelligible	
36	Up to 3600 words; understands *both, two, not today,* what to do when thirsty (hungry, sleepy), why people have stoves; understands *wait, later, big, new, different, strong, today, another,* and taking turns at play; carries out two-item and some three-item commands, such as *give me the ball, pick up the doll,* and *sit down;* identifies several colors; is aware of past and future	Up to 900 words in simple sentences, averaging three to four words per sentence; averages 170 words per hour; uses words such as *when, time, today, not today, new, different, big, strong, surprise, secret;* can repeat three digits, name one color, say name, give simple account of experiences, and tell stories that can be understood; begins to use more pronouns, adjectives, and adverbs; describes at least one element of a picture; is aware of past and future; uses commands such as *you make it* and expressions such as *I can't, I don't want to;* verbalizes toilet needs; expresses desire to take turns; communication includes criticisms, commands, requests, threats, questions, answers; 85% of speech intelligible	Starts to distinguish dissimilar speech sounds, such as the difference between *ee* and *er,* although there may be some difficulty with the concepts of *same* and *different*

B., Matos, K.A., Tavares, P., et al. (2011). The impact of maternal post-partum depression on the language development of children at 12 months. *Child: Care, Health and Development, 38*(3), 420–424.

Toddlers have a solid understanding of **object permanence** and are no longer easily distracted when a desired toy, blanket, or parent is not to be found. Many toddlers will sit patiently in front of the washing machine while a favorite blanket is laundered or stare out of a front window awaiting a parent's return. They can inadvertently put themselves in harm's way as they pursue an object or person they sense is just out of view.

The toddler period is dominated by play, but often referred to as "child's work," which is repetitive and ritualistic. When toddlers bounce a ball over and over and over again, they are not trying to drive their parents crazy. They are trying to learn about balls, and repetition is the best teacher. Toddlers' ritualistic behaviors help them

master skills and decrease anxiety, and the addition of a seemingly endless string of questions to these behaviors can test the limits of the most patient parents. These queries, however, must be acknowledged and answered in a manner that not only provides solutions but also validates and reinforces the toddler's burgeoning curiosity. The nurse explains the “terrible twos” by teaching parents and caregivers that toddlers might better be viewed as “young scientists” in need of a safe “laboratory” in which to conduct their trial-and-error research. Better now and in parents' close proximity than in adolescence, a developmental period that mirrors and repeats many of the parent-child challenges of toddlerhood.

The AAP has recommended administration of autistic screening at the 18-month preventive care visit (Miller et al., 2011). **Autism spectrum disorders** are defined as pervasive developmental disorders with onset in infancy or childhood and characterized by impaired social interactions, impaired communications, and significantly restricted activities and interests. There is no known cause. The current prevalence is 1 in every 68 American children, and almost 1 in 42 boys versus 1 in 189 girls (CDC, 2014a; Sheldrick et al., 2013). There is not a single treatment that works for all children with autism; however, there are many options available including applied behavior analysis. This involves the principle that positive reinforcement increases the frequency of the desired behavior. It is best to implement treatment early in the child's development. See http://www.autismsociety.org and http://www.myautism.org for more information.

Hearing

The ability to hear and listen to others is critical for speech and language development. Listening includes attending to what is heard, discriminating among the various qualities of sound, cognitively associating what is heard with previously learned experiences, and remembering what is heard. The quantity and quality of language to which the toddler is exposed is thought to be more important for the development of listening ability and therefore receptive language

skills than it is for the development of expressive language skills (Perryman et al., 2013). Toddlers often seek repetition of auditory input, as observed in their seemingly endless repetition of sounds, words, and combinations of words. This repetition is their way of practicing and organizing new language (Neuman & Dickinson, 2011) (see Table 18-1).

Hearing loss is one of the most common conditions present at birth. If undetected during early infancy, even mild hearing loss can impede speech, language, cognitive, and emotional development (Noritz & Murphy, 2013). Health care providers need to continue to monitor, screen, and refer children for formal audiological evaluation if they develop signs of identified risk factors for hearing loss. The timing and number of hearing reevaluations for children with risk factors should be individualized. Infants who pass the neonatal screening but have a risk factor should have at least one diagnostic audiology assessment by 24 to 30 months of age (AAP, 2011a). Early and more frequent assessment may be indicated for children with cytomegalovirus infection, syndromes associated with progressive hearing loss, neurodegenerative disorders, head trauma, or culture-positive postnatal infections associated with sensorineural hearing loss (e.g., herpes viruses); for toddlers who spent more than 5 days in a neonatal intensive care unit at birth or who received extracorporeal membrane oxygenation, exchange transfusions, or chemotherapy; and for caregivers of toddlers who are concerned because there is a family history of hearing loss (AAP, 2007, 2011a).

Younger toddlers are screened with use of **visual-reinforcement audiometry**, in which stimulus tones and visually animated reinforcers (e.g., a lighted toy) are paired and presented together. After the toddler has been conditioned to expect this relationship, the visual reinforcer is withheld, and the sound is presented alone. The toddler looks for the visual reinforcer in response to the sound, and the visual reinforcer is then presented as a reward. **Conditioned-play audiometry** is used for older toddlers and preschool children. The child is first taught to play listening games, using blocks or rings. The child learns to wait and listen for a sound and then perform a motor

task (e.g., places a block, a bucket, or a ring on a stacking stick) in response. The motor task is followed by social reinforcement. Noncalibrated toys or noisemakers and signals that lack frequency specificity are inappropriate screening methods and should be used only as gross indicators for monitoring.

Otitis media, or middle ear infection, is one of the leading causes of visits to health care providers during the toddler years and the primary reason for which antibiotics are prescribed for these children. Discussing the current literature and evidence-based reports and recommendations often helps parents understand the proper use of antibiotics, which is also imperative in preventing antibiotic resistance. When it is deemed necessary to use an antibiotic, nurses teach how to administer the medication safely and stress the importance of taking the medication at the prescribed time and for the full duration of the course, which is indicated by an empty container of medication, not by the absence of initial symptoms.

Vision

Toddlers' visual acuity is usually approximately 20/40, although gaining their cooperation for screening is often difficult and not recommended unless parents, caregivers, or health care providers identify a concern. Depth perception is still immature, although more developed than in infancy.

Amblyopia is one of the major health care concerns for this age group and occurs in 2 to 3 of every 100 children (National Eye Institute, 2013). It is defined as diminished, or loss of, vision in an eye that has not received adequate use. The eye looks normal, but it is not being used normally. Because the brain favors the other eye, the term “lazy eye” is often used. The most common cause of amblyopia is strabismus, but it may also occur when one eye is more nearsighted, farsighted, or astigmatic than the other. Occasionally amblyopia is caused by other eye conditions such as a cataract.

Amblyopia is preventable and treatable, especially if detected early. The earlier detection of amblyopia will contribute to the greater chance for a complete recovery. The AAP and the American Academy

of Ophthalmology strongly recommend that children have their eyes examined at the following times: newborn period, 6 months, 3 years, and before starting school (American Association for Pediatric Ophthalmology and Strabismus, 2015; American Optometric Association, 2015). Management of amblyopia depends on the cause and may include surgery or paralytic, autonomic, and centrally acting pharmacological agents. However, no matter what the cause, management will involve making the child use the lazy eye, the eye with reduced vision. There are two ways to accomplish this: use of atropine eye drops or patching of the stronger eye (American Association for Pediatric Ophthalmology and Strabismus, 2015). If glasses are worn with the patch, the nurse will help the parents secure them with the active toddler. Not all children benefit from eye drop treatment for amblyopia. When the stronger eye is nearsighted, the atropine eye drops may not be as effective (American Association for Pediatric Ophthalmology and Strabismus, 2015) (Box 18-7: Innovative Practice).

Box 18-7

Innovative Practice

The Eye Patch Club

It is estimated that 2% to 5% of all children have amblyopia. Prevent Blindness America is creating a support group called the Eye Patch Club for families coping with a child's amblyopia treatment. *The Eye Patch Club News* is a newsletter featuring tips and techniques for promoting adherence, stories from and about children whose eyes are patched, and professional advice from optometrists, ophthalmologists, and orthoptists. Each issue also includes a Kid's Page, and there is a classroom guide for teachers with explanations for the classroom, as well as activities for everyone to learn more about their eyes. An Eye Patch Club calendar and stickers that allow children to track their patch-wearing activity, a refrigerator magnet with helpful hints, and pen pal opportunities are also available. To

learn more about Prevent Blindness America and the Eye Patch Club, visit the website at http://www.preventblindness.org/eye-patch-club.

Strabismus is a deviation of the line of vision from the midline resulting from extraocular muscle weakness or imbalance and is commonly referred to as crossed eye. One or both eyes may turn in, out, up, or down, and this can be constant or intermittent. Marked or continuous strabismus is usually noticed early by the parents and health care providers and is therefore treated early; the subtler deviations are often unnoticed until older toddlerhood or the preschool years. Every toddler should be screened for strabismus as part of the routine eye examination that is performed by the physician or nurse practitioner during well-child visits.

Other signs of vision problems that the nurse observes or parents report in their toddlers include the following red flags:

- Rubs eyes excessively
- Shuts or covers one eye, tilts head, or looks sideways to view an object
- Has difficulty or is irritable when doing close work
- Blinks, squints, or frowns when viewing objects
- Holds books close to eyes
- Has red, encrusted, or swollen eyelids
- Has red, inflamed, or watery eyes
- Develops recurring **styes** (swelling at the edge of the eyelid)

Taste and Smell

Toddlers are beginning to take control of their world and have the capacity to taste and smell, new skills that are rapidly used. Toddlers often refuse to even taste something that looks or smells displeasing to them or eat something that they recall as tasting terrible. They are able to react accurately to a sensation that a taste or smell arouses in them, and they begin to learn conditioned association between certain smells and culturally acceptable values. Foods and smells found in one

family or culture become palatable and accepted, and those that are unacceptable become displeasing. Many of our adult eating habits, food likes and dislikes, and visceral responses to odors have their roots in this period.

Self-Perception–Self-Concept Pattern

According to Erikson (1995, 1998), the developmental task of toddlers is to acquire a sense of **autonomy** while overcoming a sense of **doubt** and **shame**. To exert autonomy, toddlers must relinquish the dependence on others that was enjoyed during infancy. Continued dependency has the potential to create a sense of doubt in toddlers about their ability to take control of, and ultimately take responsibility for, their own actions. Toddlers seem to thrive when parents can accommodate their increasing autonomy yet maintain a strong parenting presence that includes a full measure of patience, enough parental self-confidence to set appropriate limits, and the ability to realize that their toddler's negative behavior is not directed at them and their egocentrism is not a reflection on them.

The toddler must explore the world, not only the physical aspects but also the interpersonal aspects of relationships, to develop a true sense of autonomy. Exploring the physical world involves poking into, climbing onto, crawling under, tasting, smelling, and taking apart the objects encountered. The child explores relationships with others by searching for the limits of the child's power: If a “no” or a temper tantrum means control of another person's behavior, the child learns that one's own self is more powerful than the other person's self. The toddler continually practices separateness to develop a sense of autonomy.

This process can be frustrating and confusing for parents. The toddler may say a vehement “no” when offered a drink and then scream and cry when the drink is taken away; the parents may wonder whether or not the toddler wants the drink. Likely the answer is “yes,” but the toddler may also need to express autonomy by refusing it. Occasionally the same toddler who displays a strong need for autonomy spontaneously cuddles or even clings to a parent. These

conflicting desires can be confusing to both the parent and the toddler. The toddler's need for more autonomy may conflict with parental expectations, safety limits, or the rights of other children or adults. Any of these conflicts result in feelings of frustration. A typical toddler response to frustration is the well-known temper tantrum.

Nursing Interventions

The nurse assesses the toddler-parent relationship to determine the following:

- How is the toddler expressing the need for autonomy?
- How do the parents perceive these actions?
- How does the toddler respond to frustration in exploring the environment or controlling personal and others' actions?
- How do the parents respond to the toddler's display of frustration?
- What provisions are the parents making to allow safe choices for the toddler?

The nurse's teaching focuses on the aspects that are troublesome for the toddler-parent relationship. The following examples are some general concepts to include:

- Match the environment to the child's needs and abilities. Childproof the home such that the child can explore safely. Provide toys that the child can master. Give opportunities to play with more challenging toys, but do not make these toys the rule.
- Give advance notice of a change in activity, such as lunch or nap time. Use transition rituals and objects.
- Do not offer a choice if there is not one. For example, rather than ask if the toddler wants to take a bath, say “It is time to take a bath, do you want to take it upstairs or downstairs, or do you want to start at the face and move down to the toes or start with the toes and wash the face last?” This allows the toddler to be in charge and the task of bathing to be achieved.
- Set and enforce consistent limits such that the toddler will come to develop control within these limits.

- To prevent temper tantrums, keep routines simple and consistent, set reasonable limits and give rationales, avoid “head-on clashes,” and provide choices.
- If temper tantrums occur, provide a safe environment for the toddler, identify the tantrum's cause, and help the toddler regain control. Do not reason, threaten, promise, hit, or concede. Respond consistently and follow through on discipline free of anger. Overcriticizing and restricting the toddler may dampen enthusiasm and increase feelings of shame and doubt.
- Praise the toddler's skills and abilities. Never miss an opportunity to catch your toddler being good. Be positive. Remember to say “yes” once in a while.

Roles-Relationships Pattern

By toddlerhood, children typically know their mother, father, and older siblings and have established some form of reciprocal relationship with them (Herd et al., 2014). Toddlers' capability for relationships is limited and usually reflects their egocentric approach to everything else. Parents' and siblings' roles are understood, just like everything else in their lives, in terms of how those roles relate to the toddler. One family member may be the fixer of toys or the comforter of bruises, another the troublemaker who takes away toys.

Toddlers are interested in everything, and their parents' and siblings' activities and possessions are often imitated and preferred. Frequently the desire to be like or have something that belongs to a sibling creates sibling rivalry. This happens between toddlers and their older siblings, but even more when a new, younger sibling is introduced (Figure 18-5). A new baby who is often loud, unable to play, unable to be touched or explored too vigorously, and demands and gets too much parental attention quickly becomes a nuisance to toddlers, who have been known to inform their parents that they can “take the new baby back where it came from now.” Realizing the new sibling is here to stay, toddlers often regress, reverting to earlier, previously abandoned infantile behavior such as losing toileting skills,

wanting to be fed or dressed, or even communicating by “baby talk.” They are usually trying to retain or regain a sense of mastery and, once reassured, will progress. This process is not the end of sibling rivalry but only the beginning of what will assume many forms and require ongoing negotiation from all family members. Parents cannot stop sibling fighting by forbidding it, but reasonable limits can be established. One way to deescalate fighting is to remove the reward of the fight. Generally, the desired outcome in the toddler's mind is to see the self-rewarded and the sibling punished. When parents do not reward the toddler or punish the sibling, or when they do not take sides, the gain is missing and fighting becomes less satisfactory. This approach does not mean that all fighting will stop, but the child will look for other ways of getting approval.

FIGURE 18-5 It is a big change for a toddler when a new baby is introduced to the family.

Sibling relationships and parent-child relationships can be difficult subjects for parents to discuss. Parents may think that any hint of discord indicates an unhealthy family (Wulff et al., 2015). The nurse includes normal family development and role relationships as part of the anticipatory guidance given during the toddler years (Kochanska et al., 2013). Toddler behaviors are frustrating for all parents, and discipline can often be influenced as much by parental emotions as by parenting knowledge and skill (Gravener et al., 2012). When parental anger, depression (Herd et al., 2014; Sturge-Apple et al., 2012; Wiggins et al., 2014), criticism, and restrictions go unchecked, physical and

emotional abuse can occur.

Child Abuse

Child abuse and maltreatment is not limited to a particular age or particular families (Dodge et al., 2014). However, it is more likely to occur with a major change or turmoil (CDC, 2014b, 2015c; Turner et al., 2012) in the family and when parental role models were abusive. Toddlerhood is a trying time for the most patient of parents, and nurses are alert to family changes and stresses as well as to warning signs of abuse (Box 18-8). Many injuries are difficult to differentiate from accidental injury and, at times, may even be confused with culturally appropriate healing practices (Box 18-9: Diversity Awareness). However, the toddler years have the greatest incidence of child maltreatment, with 27% of nonfatal cases reported for children aged 3 years or younger and 70% of deaths from child maltreatment occurring in children younger than 3 years (CDC, 2014b, 2015c). Nonfatal cases appearing in emergency departments, pediatrician offices, and day care centers may be the only opportunity for health care providers to prevent later death from continued child maltreatment.

Box 18-8

Warning Signs of Child Abuse

- Parental delay in seeking help
- Inconsistencies in the history of how the injury occurred
- Injury inconsistent with the history or the child's developmental capability
- Old, unexplained fractures evident on radiographs
- Bruises confined to back surface of the body—neck to knees

- Bare spots and broken hair
- Pattern of injury or bruising descriptive of object used to inflict injury (belt or belt buckle, hand, cigarette, hot water)
- Burns with sharply demarcated edges or circumferential patterns
- Perineal injuries of any kind

For more information about recognizing signs of child abuse, visit the Child Welfare Information Gateway at https://www.childwelfare.gov/pubs/usermanuals/childcare/.

Box 18-9

Diversity Awareness

Evaluating a Child for Child Abuse With Cultural Sensitivity

Nurses are required by law to report cases of suspected child abuse to Child Protective Services. The nurse who takes a careful health history may discover that what might appear to be characteristic burns or bruises associated with child abuse may instead be the product of a traditional culturally appropriate healing practice. The following are two examples of healing practices found in the Pacific Islander and Asian populations that might create such confusion.

Coining (*Cao Gio*)

Coining is a common healing practice used among Pacific Island and Asian families within the United States. Traditionally, coining is used for conditions associated with "wind" illnesses, as well as a wide variety of febrile illnesses. The lesions seen from coining are produced by rubbing a warm oil or balm on the skin and firmly abrading the skin with a coin or special instrument. The practice produces linear petechiae and ecchymosis on the chest and back that often resemble strap or belt marks. The appearance of the deep red-

purple skin color is confirmation that the person had bad wind in the body.

Cupping (Ventouse)

Cupping involves the creation of a vacuum inside a special cup or glass by burning the oxygen out of it and then promptly placing it on a person's skin surface. Cupping draws blood and lymph to the body surface that is under the cup or glass, increasing local circulation. The purpose for doing this is to remove cold and damp “evils” from the body or to assist blood circulation, or both. The procedure is frequently used to treat lung congestion. The resulting circular ecchymotic marks are approximately 2 inches in diameter and resemble nonaccidental trauma.

Typically, parental responses to childhood injuries include a spontaneous reporting of the details of the illness or injury accompanied by concern, questions about progress and discharge, difficulty in leaving the child, and an attempt to identify with the child's feelings. These parents may also experience guilt for not protecting the child from the accident and may offer gifts to compensate for these feelings of guilt. In contrast, neglectful or abusive parents are often hesitant to provide information about the illness or injury; they may be evasive or even contradict themselves, irritated by the inconvenience of being asked questions. Abusive parents may not exhibit guilt feelings and often contend that the toddler was solely responsible for the injury.

Although these signs of potential abuse are certainly not present in all abusive parents, their presence alerts the nurse to assess and observe further. The nurse also remembers that some of these signs may be found in nonabusive parents, and that the presence of these signs serves only as a cue for further assessment. All nurses are required by law to report any and all suspected child abuse to the local child protective services agency.

Sexuality-Reproductive Pattern

The toileting process, during which attention is focused on the genital area, may precipitate the toddler's curiosity about genital organs. The nurse includes this aspect when teaching about toilet training, giving parents time to consider their feelings and decide on their approach to genital exploratory behavior and **masturbation**. Some parents accept the child's curiosity, whereas others see this as an opportunity to introduce their own sexual values and taboos (Healthy Children, 2015).

The nurse encourages parents to approach this curiosity and exploration, as well as masturbation, as a normal developmental process. These behaviors provide toddlers with an opportunity to become better acquainted with their bodies. Many parents are uncertain about the vocabulary they should use and often create cute, unrelated words rather than provide the correct anatomical terms. The use of cute alternative words is often a reflection of parental discomfort or embarrassment. Using correct terms will help toddlers develop accurate knowledge about sexuality and communicate more effectively if inappropriate touching by others occurs. For example, a young boy was initially ignored by day care providers because he said an older boy ate his "pickle." After repeated episodes, the parents were contacted because the child seemed so upset (even though day care workers gave him a new pickle to eat). The parents shared that "pickle" was their name for penis.

Coping–Stress Tolerance Pattern

Perceptions of events and reactions to them are filtered through children's developing cognitive, emotional, and social capacities. The relevance of life events and the child's vulnerability to their impact depend on the given developmental period (see the case study and care plan at the end of this chapter). A child's **temperament**, which is defined as an individual's style of emotional and behavioral response across situations, especially those involving change or stress, serves as a foundation for coping (Burns et al., 2013). Chess and Thomas (1986) originally described three common temperament patterns that they believe are innate: the easy child; the difficult child; and the slow-to-

warm-up child. The easy child is cuddly, affectionate, and easy to manage. Children with a difficult temperament, however, are less adaptable, are more intense and active, and have more negative moods.

Although temperament has generally been accepted as inborn, it is influenced by environmental characteristics and exerts an influence on psychosocial adjustment by way of its effect on parent-child interactions. Nurses assist parents in recognizing their toddler's innate behavioral qualities as expressions of temperament and in developing management strategies. According to the goodness-of-fit interactive model of temperament, adults can accommodate their demands and expectations in ways that match the child's behaviors, including learning strategies to help toddlers adapt positively to social expectations.

Toddlers are developing new ways to cope with the myriad of new stresses that come with being a toddler. As is typical of their stage of development, coping is egocentric and reflective of their need for autonomy. Typical stressors include new siblings, babysitters, day care, toilet training, parental limit setting, and an endless string of tasks involving skills they have yet to develop.

Toddlers often imitate their parents' behavior, and this includes their methods of dealing with stress. They also regress, at times, to earlier infantile behavior when overwhelmed, until they regain some sense of mastery. Parents can help to anticipate and prepare toddlers for stressful experiences before they happen. However, they need to remember that toddlers' sense of time and ability to recall are limited. Preparations should be honest, simple, and focused on what the toddler will experience. Enough time should be allowed for the toddler to rehearse the coping behavior with the parent, but not so early before the event that the toddler forgets.

The nurse helps the parents anticipate developmental stressors and suggests age- and temperament-appropriate coping behaviors for toddlers. Early efforts at dealing with stress are an essential step to more mature coping responses as the child grows (Shonkoff & Garner, 2012).

Values-Beliefs Pattern

Healthy behaviors are expressions of positive values and beliefs. These values and beliefs are learned, and their recognition and acceptance are fundamental to the integrity of every child. Toddlers believe rules are absolute and behave, according to Kohlberg, out of a fear of punishment. However, toddlers' environments should not only help them become aware of right and wrong but also contribute to their sense of security, belonging, and autonomy. Development of moral integrity is enhanced if toddlers believe they are valued (Arthur et al., 2012).

Because most of toddlers' developing values and beliefs depend on their interactions with parents, the nurse's assessment questions are often directed to or focused on the parent or caregiver. The following are some examples of questions asked by the nurse:

- What are the family's values and beliefs about what is right and wrong?
- How does the parental approach to limit-setting reflect these values and beliefs?
- What religious, spiritual, or cultural traditions and activities do the family have?
- How is the toddler included in these traditions and activities?

Children are exposed to and begin to participate in and imitate their family's religious rituals and practices during toddlerhood. They are often taught prayers and songs with a religious theme that are tied into what the family believes are right and wrong. Toddlers may be able to learn the words to these simple prayers and songs, but parents should be cautioned that knowing the words does not mean that toddlers understand the full meaning of what is said. This early introduction into the family's religious beliefs is important as a socialization factor but should not be assumed to produce a good child.

The creation of values and beliefs in young children is related to their developmental stage and is reflected in their behaviors. An important aspect of teaching young children what is right and wrong

involves stating what acceptable behavior is and then reinforcing the behavior when it occurs. Parents often attend to toddlers only when they are misbehaving, leaving them alone when they are being good. In this scenario, toddlers receive no attention for acceptable behavior but gain their parents' attention when they misbehave. The nurse can remind parents to catch their toddlers being good and give them the same or more attention.

Environmental Processes

Physical Agents

Accidents

"If a disease were killing our young children in the proportions that injuries are, people would be outraged and demand that this killer be stopped."

C. Everett Koop, MD, Former Surgeon General

Toddlers are at high risk of accidental injury because they lack judgment and experience and have only rudimentary problem-solving skills, limited physical coordination, and a heightened level of curiosity about their environment. There are also behavioral and environmental factors that increase toddlers' risk of injury, such as being in new situations (Kuhn & Damashek, 2015). Most parents think that it is natural for children to get hurt and that childhood injuries are just a part of growing up. However, most injuries are predictable and preventable and can cause disabilities requiring long-term care. Furthermore, they can cause more deaths than all childhood diseases combined.

One in every 10 toddlers who come to the emergency department is treated for accidental injury. Male toddlers tend to have more injuries than their female counterparts, but the overall numbers of accidental injuries peak during toddlerhood for both male and females. A second peak occurs for males during adolescence. Major causes of accidental injury in toddlers involve structural hazards, sports, drowning, burns, motor vehicles, and poisoning.

Recent research indicates that although overall injury rates for young children have decreased in the past 20 years, injury mortality rates remain higher in black American and American Indian/Alaskan Native children. The young children in these groups had higher injury and death risk for residential fires, suffocation, and poisoning. These

findings suggest new strategies and approaches are needed to narrow the disparities that continue to exist.

Structural Hazards

Houses and other buildings can be hazardous for toddlers. Their desire to explore lures them to locations that older children or adults would not consider. The toddler will climb onto furniture or fixtures, out of windows, or into small spaces. Injuries that result from these explorations can range from minor scrapes and bruises to fatal head injuries. Ideally, homes are "baby-proofed" before the infant begins scooting and crawling and toddler-proofed before the toddler becomes increasingly mobile. Parents should reassess the safety of their home as their child acquires new skills. Injuries to toddlers occur most often when they fall from furniture, high chairs, changing tables, stairs, windows, and playground equipment. When the child or family visits the home of a friend or relative, it must be inspected for hazards, or the toddler must be confined to one safe room. Many injuries occur in unfamiliar environments.

Preventive measures for structural hazards include the following:

- Do not leave a toddler unattended.
- Use gates at the top and bottom of stairways, and at doors.
- Keep chairs away from countertops and tables to prevent toddlers from climbing.
- Securely anchor large television screens and other electronic equipment that can fall onto toddlers.
- Lock doors to dangerous areas and use gates and window guards.
- Store guns in a locked, safe area out of reach.

Toys

Toys commonly found in homes are another source of injury. Parents should inspect not only the toys that are in their own homes but also the toys given to the toddler outside the home by relatives, friends, babysitters, or day care personnel (see the case study and care plan at

the end of this chapter). Many toys that are likely to be safe for older children are extremely hazardous for the toddler. Of concern are small, removable parts, magnets and batteries, toxic paint or stuffing, sharp edges, and flammable material.

Sports

Although sporting and recreational equipment is recognized as a major source of accidents in older children and adolescents, parents and health care personnel occasionally forget that such equipment can also be dangerous to toddlers. Improper storage of this equipment is a primary danger. Firearms that are left loaded and unlocked are deadly hazards, and bodybuilding weights and other heavy equipment easily overwhelm toddlers, who may pull these objects down on themselves. Toddlers should always be supervised closely, especially in new environments or on playground equipment.

As toddlers become more mobile, they are introduced to riding toys, tricycles, and bicycles. Nurses remind parents about the need for, and in most states the requirement of, bicycle helmets that are fitted properly and worn every time the toddler rides or is a passenger on a bicycle.

Drowning

Children between the ages of 1 and 3 years are at the highest risk of drowning because most do not know how to swim and do not have the skills to keep their heads above water or to get out of the water. Toddlers can drown in water just deep enough to cover their noses and mouths. Although swimming pools and other natural bodies of water are a big part of the problem, even pails of water, toilets, bathtubs, and wading pools are dangerous. When toddlers fall into a pail of water or a toilet, it is hard for them to straighten up because all their weight is forward. Toddlers should never be left unattended—even for a few seconds—near a bathtub, hot tub, wading or swimming pool, toilet, pail of water, or small creek. All swimming pools should be fenced and have self-closing gates and latches. Toddlers must be

supervised constantly and competently whenever they are near any body of water regardless of its size and should be fitted properly with personal flotation devices whenever they are on a boat.

Burns

Each year 28.1% of US children from birth to 5 years of age require emergency department treatment (US Department of Health and Human Services, 2012). Hot tap water, boiling water, coffee, tea, and food are the most common sources of injury resulting in scalds from hot liquids. These very painful and often debilitating injuries often occur as toddlers begin to gain mobility and explore their environments, inadvertently touching hot surfaces or spilling hot liquids on themselves. They may also put their mouths on live electrical cords or their fingers into electrical sockets and become seriously burned, as well as tip their walkers or themselves into fireplaces or woodstoves.

The nurses' role is to educate parents regarding the following:

- Never eat, drink, or carry anything hot while holding a child.
- Lower the water heater temperature to between 120°F and 125°F.
- Never leave hot beverages or foods within a child's reach.
- Put children in a playpen while cooking.
- Never leave a toddler unattended in the bathtub. It takes only a moment to turn on the hot water.
- Put screens around fireplaces or woodstoves.
- Do not let children handle food directly from the microwave oven.
- Use burners at the back of the stove and turn pot handles in toward the stove.
- Install and maintain smoke detectors, replacing batteries annually.

Motor Vehicles

Motor vehicle–related injuries, which include both passenger and pedestrian injuries, are the primary injury in children from 1 to 4 years

of age. For the toddler, passenger injury is more frequent and often involves the lack of use or misuse of child safety seats. Child safety seats, when properly installed and used, have reduced the risk of death and serious injury to children. Unfortunately, improper installation and use of child safety seats are widespread problems, with some experts reporting that more than 72% of them are misused in some way (CDC, 2015b). Certified child passenger safety technicians are trained in installing car safety seats properly and can help parents make sure their children are as safe as possible on the road. To find the closest inspection station, the nurse can visit or direct parents to visit http://www.seatcheck.org or call toll-free 866-SEAT-CHECK (866-732-8243).

The rear-facing child safety seat supports a young child's head, neck, and spine, helping to reduce stress to the neck and spinal cord in a crash. When children reach 2 years and their child safety seat's upper weight or height limit, the nurse confirms with the parents that they can switch to forward-facing child safety seats. All children younger than 12 years should be seated in the rear seat. Rear seat position is safer than the front seat for all child safety seats, and a special warning has been issued that no child should be seated in the front passenger seat if the car has air bags (AAP, 2011b) (http://www.exchange.aaa.com/safety/child-safety/safety-seat-guide).

During the toddler years, it is safest to keep the child in a forward-facing rear seat with a harness until he or she reaches the seat's maximum height or weight (40–65 pounds). Children can use a booster seat when they have outgrown the weight or height limit of their forward-facing harnesses. Children at this stage are not yet ready for adult safety belts and should use belt-positioning booster seats until they are at least 4 feet 9 inches tall and between 8 and 12 years old. Safety belts are designed for 165-pound male adults, so it is no wonder that research shows poorly fitting adult belts can injure children. When a child can sit with his or her back straight against the vehicle seat back cushion and with knees bent over the seat edge without slouching, it is time to switch to an adult safety belt (AAP, 2011b) (http://www.exchange.aaa.com/safety/child-safety/safety-seat-

guide). The nurse can provide a list of approved car seats and local retail outlets or agencies that sell, lend, or rent car seats.

Parents should be warned that toddlers may be injured or killed when they are hit by drivers backing up in their own driveways and often by members of their family or nearby neighbors. They are too small to be seen by a driver backing up and are quick to run out after a departing parent or relative who thinks they are still safely inside.

Biological Agents

Bioterrorism

Recent events have heightened concern about bioterrorism, and concerns about agents such as *Escherichia coli* (E. coli) are becoming more common questions for health care providers (AAP, 2013b). Other bioterrorism risks that are of concern for children include botulism, salmonellosis, and typhus. Children are especially at risk of these bacterial hazards because of their physiology. Compared with adults, they have a faster respiratory rate, increased skin permeability, higher skin to body mass ratio, and less body fluids (AAP, 2013b). Nurses provide information that can assist parents in dealing with their toddler's and their own fears. Nurses encourage parents to:

- Talk about their fears and worries.
- Stick to family diet routines that help toddlers maintain a varied and nutritious diet.
- Supervise toddlers' television viewing.
- Educate themselves, the best protection against unnecessary fear. Toddlers will be less fearful if they see that their parents are not afraid.

Many parents feel that toddlers, because of their immature immune systems and varied diet, are especially vulnerable to certain agents such as *E. coli*. Fearful parents might request antibiotics when they hear of an *E. coli* outbreak, just to be certain their child does not get sick, despite confirmation the child was never exposed to contaminated food. The nurse should reassure parents and explain

that giving children antibiotics when they are not needed can do more harm than good. Many antibiotics, especially those identified for *E. coli* management, have serious side effects, and use of them when they are not needed can lead to the development of drug-resistant forms of bacteria. If this happens, the antibiotics will not be able to kill the resistant bacteria the next time the child needs the same antibiotic to treat common ear, sinus, or other infections.

The AAP website addresses numerous issues related to bioterrorism and children (http://www.aap.org), including the development of a teaching toolkit for parents to use with their children.

Chemical Agents

Poisoning

Poisoning happens 10 times more often among young children aged 1 to 4 years than in their older counterparts. Toddlers aged 1 to 2 years are at the greatest risk. They are becoming more mobile, enabling them to explore and discover poisonous substances in the home. These include prescription and over-the-counter medications, alcohol, household products, plants, cosmetics, lead-based paint, and cigarettes (Box 18-10: Quality and Safety Scenario). They are also at risk because they still use their mouths as a way of exploring. Although many parents take precautions against poisoning in their own homes, some forget that toddlers can be poisoned away from the home, while visiting grandparents or other relatives (e.g., see the case study and care plan at the end of this chapter).

Box 18-10

Quality and Safety Scenario

Preventing Accidental Poisonings in the Home

- All household, garden, and car products should be kept out of reach.

- Keep medications out of reach in locked cabinets.
- Use childproof caps on medication.
- Keep all products and medication in their original containers for easy identification.
- No poisonous plants should be kept in the house. A list, which includes poinsettia, amaryllis, aloe vera, English ivy, mistletoe, chrysanthemums, and spider plants, is available from local poison control centers.
- Avoid outdoor plants and shrubs that are poisonous, including azaleas and chrysanthemums.
- Supervise the toddler's activity at all times.
- Post the National Capital Poison Center telephone number (1-800-222-1222) next to every telephone, including your cell phone.

The toddler, because of limited experience and cognitive level, is unaware that these items are harmful. Many emergency department calls and visits are precipitated by a toddler's ingestion of a potentially or actually harmful substance. These incidents are likely to occur in the kitchen, bathroom, bedroom, or work area, and are usually discovered by the parent or caretaker who finds an open or empty container or a half-eaten leaf or other substance.

When parents or caregivers suspect that a toddler has ingested a poisonous substance, they should call the poison control center, even if the child appears perfectly healthy. Each center is part of a nationwide effort to provide immediate information about poisonings. Parents should not attempt to induce vomiting without specific instructions from the center. Vomiting can cause further harm if the child is drowsy, unconscious, or convulsing; or if the substance ingested is corrosive, such as lye or a strong acid. When vomiting is recommended by the poison control center, instructions are often

given to use ipecac syrup to stimulate the vomiting rapidly. This medication should be stored as carefully as any other medication or hazardous household product and replaced often because of its short shelf life.

Chronic poisonings, such as lead poisoning, are often undetected until irreversible damage has occurred. Primary prevention involves teaching parents about risk factors and dangers of lead poisoning and the importance of a diet that encourages decreasing fat intake, because lead is retained in fat. Vitamin C, calcium, and iron intake reduce lead levels in the body. Secondary prevention involves performing periodic screening of blood lead levels in all young children identified as at risk. Consumer protection laws in the United States require that all toys and furniture manufactured for small children be free of lead-based paint products. However, imported toys and furniture or antique and older family furniture or paint in older houses may have been painted with a lead-based product.

Determinants of Health

Social Factors and Environment

Day Care

During the toddler years many parents return to work or decide that an experience in a group setting would be beneficial for their child. The nurse can provide counseling about the decision to place a child in day care and the resulting emotions, as well as guidelines for selecting a safe child care or day care provider (Dodge et al., 2014).

The US Department of Health and Human Services Administration for Children and Families recommends a four-step approach as a guideline for selecting a child care provider or day care center (see http://www.acf.hhs.gov/programs/occ/parents/index.htm) (see Chapter 17):

- Interview potential child care providers and observe the program or setting.
- Ask about cost; enrollment; ages served; daily activities; accreditation and licensing regulations; caretaker credentials and experience; and policies about visiting, illness, and nutrition.
- Look at provider-child interactions, safety, and the quality of the learning material and toys.
- Check references.
- Talk to parents with children in the center or being cared for by the provider about discipline and responsiveness to parents, and talk to local child care resource or referral agencies and licensing offices.
- Make a decision based on specific criteria.
- Think about safety, values, fit for you and your toddler, and affordability.
- Get and stay involved.
- Talk to the provider regularly about how your child is doing, to your child about what the children are doing each day, and to other

parents.

- Visit often, announced and unannounced, and at various times of the day.

Many organizations have developed guidelines and checklists on choosing child care. Child Care Aware (http://www.childcareaware.org or 1-800-424-2246) is a national initiative designed to improve the quality of care and increase the availability of high-quality child care in local communities. Services include helping to find child care and connecting parents with local child care resource and referral agencies. Their brochure, *Give Your Child Something That Will Last a Lifetime—Quality Child Care,* outlines the steps to finding child care and includes an observation checklist.

Regardless of the reasons for the parents wanting or needing day care for their child, the traditional expectation of caring for the young child at home continues to influence the parents' concept of what they should do for their child. Parents must be reassured that a day care environment congruent with the family environment is not detrimental to the child. If a child has been placed in a setting that is detrimental to physical or emotional development, the parent may need assistance in selecting an alternative setting. Changes in caregivers are difficult for toddlers, and regressive behaviors may surface during transition periods.

Culture and Ethnicity

Culture influences everything we do, know, and believe. Each culture possesses its own values, attitudes, and practices with regard to family and childrearing. Toddlers continue to be shaped by the cultural values and beliefs of their parents and families, the first of many socializing forces they will encounter. As their world expands, other forces and subcultures, including peers, the media, and their schools, will also be encountered.

Unlike older children, toddlers do not question the cultural practices of the family. The toddler who refuses to do certain expected things usually does so out of a need for autonomy and control rather

than a questioning of beliefs. However, nurses remind parents of this, because parents may be feeling the pressure of cultural norms and expectations. This is especially true for families who have emigrated recently.

Nurses are prepared to provide culturally sensitive and competent care. Knowledge and respect for various cultural world views, customs, values, and traditions are needed to negotiate different approaches in developing a health-promotion plan with families. Health care practices are culturally influenced. For example, if a culture views immunizations as dangerous or unnecessary, the toddler may be unprotected from certain communicable diseases. Incorporation of knowledge, respect, and negotiation facilitates the development of a therapeutic relationship grounded in trust, as well as effective, high-quality health care outcomes (Burns et al., 2013).

Levels of Policy Making and Health

A lack or paucity of economic resources is capable of affecting the toddler's health and well-being. According to the Children's Defense Fund (2015), in 2014, more than 15.5 million American children were poor, with the poorest being of color and younger than 6 years (http://www.childrensdefense.org/policy/endingpoverty/). Toddlers who live in poverty have higher mortality rates, poorer health, poorer growth, and more physical morbidity from respiratory tract infections, gastrointestinal tract infections, anemia, asthma, dental caries, otitis media, and visual loss, as well as higher rates of accidental injury and psychological and developmental disorders (Burns et al., 2013).

In 1997, the federal State Children's Health Insurance Program was developed to address this need. Because of this program, the number of uninsured children is at a historical low. Approximately 57% of all children in the United States are enrolled in Medicaid programs, and another 7.3 million are uninsured. Other services that are available to low-income families with toddlers include Temporary Assistance for Needy Families and the Special Supplemental Nutrition Program for Women, Infants, and Children. The nurse can play a critical role in

mobilizing these resources for families. The Affordable Care Act has increased access to preventative care for toddlers with private insurance coverage. Private insurance companies are no longer allowed to deny coverage for a preexisting condition. (See more at http://www.childrensdefense.org/policy/health/#sthash.URCLwhGu.d

Legislation

Local and state legislation specific to the toddler is directed primarily toward safety and injury prevention. Many states have passed laws requiring the use of child safety seats, bicycle helmets, and temperature limits for household hot water heaters.

Each state has passed laws that provide protection for a child or developmentally disabled adult, define abuse and neglect, require that a report be made to a designated agency in the case of actual or suspected abuse or neglect, and define the responsibility of the protecting agency. These laws also provide for a central registry of reported cases of abuse. Nurses are aware that they are required by law to report suspected child abuse, and should familiarize themselves with the child abuse and neglect laws in their states.

On the basis of current neuroscience and developmental research, as well as "data from a recent 50 state study of current health, child care, and family support policies," Knitzer (2008) proposes five care policy challenges: enacting a national family leave; expanding access to child and family programs such as Early Head Start; providing policy incentives and resources for high-quality infant and toddler child care; strengthening the early identification and treatment for infants and toddlers at risk of poor development; and building a policy framework to support, in every state, an infant and early childhood mental health infrastructure.

Another legislative issue for the toddler is the Education of the Handicapped Act amendment of 1986 (Public Law 99-457). This law creates programs that assist states in planning, developing, and implementing systems within states for handicapped children from birth to 3 years of age. Nurses who work with young children with disabilities need to investigate and familiarize themselves with the

programs in their states.

Health Services/Delivery System

The health of toddlers is significantly affected by the health care delivery system in the place where they live (Burns et al., 2013). Private physicians, nurse practitioners, and public well-child clinics are the most frequently used resources for ongoing health maintenance or illness care for toddlers. Health professionals specializing in pediatrics often coordinate their efforts to provide optimal health care for young children. For young children who do not receive routine health care, some public clinics sponsor special immunization days. Retired health care professionals donate their time at free dental clinics for children.

Each health care visit includes an interval history, assessment of growth and development, physical assessment, discussion of age-appropriate developmental concerns, and anticipatory guidance. Immunizations are given according to the current CDC (2015a) Recommended *Immunizations for Children From Birth Through 6 Years Old*. Both provider and parent schedules are easily found on the CDC website: http://www.cdc.gov/vaccines/schedules. The nurse informs parents that they can anticipate and keep track of their toddler's immunizations with the CDC Childhood Immunization Schedule. Recently, there has been controversy about a possible relationship between childhood immunizations and autism spectrum disorders. Some parents are choosing not to vaccinate their children as recommended by the CDC, which has resulted in multiple measles outbreaks in regions of the United States (Gostin, 2015). Despite what beliefs are held by certain groups of people, researchers have not found anything to indicate that vaccinations contribute to development of autism (Destefano et al., 2013; Larru & Offit, 2014).

Toddlers need to explore their environment to master it, and this is also valid for their health care encounters. They may need to observe and listen as their parents interact with the health care providers, be introduced to and allowed to manipulate examination equipment, and be given simple explanations and choices so that they can maintain

some degree of control. Taking the time to enlist the cooperation of a toddler will make the health care visit more productive and conducive to information exchange and health care teaching.

Nursing Application

Educating parents about health promotion and disease prevention in the toddler age group is similar to that for the infant. The nurse involved with the family provides education that is focused on the physical and developmental changes that are expected to occur in the toddler stage. This is the period of life from approximately 18 months to 3 years of age.

In addition to educating the parents, the nurse is able to begin to teach some health-promotion activities to the toddler. Examples of this type of toddler education are nutrition and oral hygiene. At this stage of development, it is crucial that caregivers model healthy behaviors and eating patterns. Parents may need education from the nurse on providing age-appropriate food choices while discouraging the intake of empty calories.

The nurse dealing with the toddler and the family can engage in screening activities. Assessments can be performed to evaluate the toddler for hearing loss and vision disturbances. Some conditions associated with vision or hearing can be treated if detected early.

As toddlers begin to explore their autonomy, they become at risk of accidental injury. Parents should be educated about objects on which the child may climb, possibly creating a crush or entrapment injury. They should also be aware of hazardous toys, sports equipment, drowning, burns, poisoning, and motor vehicle safety. In addition to this, medical personnel must remain alert to the potential for child abuse and report any suspicious injuries.

Another important element of health promotion with the toddler age group is educating the parents about routine health examinations and the childhood immunization schedule. Nurses need to remain informed about changes in immunization recommendations and educate families as the changes occur. Nurses working with families need to remain knowledgeable about the resources available in the community that may provide free or low-cost injections.

Case Study

Grandparents Provide Care: Dante

Maria and Jose are the parents of 18-month-old Dante. They plan to take a week-long vacation while leaving Dante with his grandparents at their house. Because Dante is the first grandchild, the older couple is eager to spend time with him, but they have expressed concern about caring for a toddler.

Reflective Questions

- What do the parents need to discuss with the grandparents concerning safety issues?
- What psychosocial issues of a toddler are important for both the parents and the grandparents to consider?
- What resources are available for today's grandparents?

Care Plan

Grandparents Provide Care: Dante

***NURSING DIAGNOSIS: At risk of injury related to change in environment and change in primary caregiver(s)**

Definition

At risk of injury as a result of environmental conditions interacting with the individual's adaptive and defensive resources

Related Factors

- Heightened level of curiosity about environment
- Lack of more mature judgment and experience

- Limited height and physical coordination

Risk Factors

- Change in living environment to grandparents' home
- Grandparents home not “childproofed”
- Change in primary caregiver(s) from parents to grandparents
- Grandparents not up-to-date with caregiver/safety knowledge for toddlers

Expected Outcomes

- Grandparents will receive instruction regarding toddler care/safety.
- Grandparents will take necessary precautions to childproof their home.
- Grandparents will identify available resources to assist in toddler care/safety.
- Toddler will remain free of injury while in grandparents' care.

Interventions

- Surveillance: safety.
- Conduct a safety check in grandparents' home/community.
- Provide a safety checklist for grandparents.
- Assist grandparents in identifying resources/support.
- Contact community groups to emphasize community safety concerns.

- Risk identification.
- Identify potential risk factors in grandparents' home/community.
- Teaching: toddler care/safety.
- Teach grandparents about toddler care/safety issues.

---

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

This period can be an exciting and challenging time for both toddlers and their parents. Parents who have encouraged their toddlers' desire to explore can now delight in their developing sense of adventure as they enter their preschool years. The world is a wonderful place for the toddler who has known and experienced support, affection, and protection.

Preschool Child

Susan Ann Denninger, Kristi Coker, Kevin K. Chui

OBJECTIVES

After completing this chapter, the reader will be able to:

- Explain the physical and psychosocial changes occurring during the preschool years that influence child and family health needs.
- Discuss the concepts of cognitive development of preschoolers using Piaget's theory.
- Review the *Healthy People 2020* concepts that pertain to preschool children and their families.
- Describe family teaching and nursing support for the typical sleep disturbances of the preschool years.
- Differentiate the nursing roles regarding vision and hearing screening for preschoolers.
- Compare coping skills of preschoolers with those of younger children.
- Outline the primary prevention immunization requirements for preschoolers.
- Identify warning signs of cancer in preschoolers.
- Recognize signs, symptoms, and clinical features of and risk factors for asthma in preschoolers.
- Identify the major causes of injuries during the preschool years.

KEY TERMS

Acute lymphocytic leukemia

Think About It

Aggressive Behavior

Phillip, age 4 years, started preschool 2 weeks ago after spending his early years at home with his mother and his 18-month-old sister. His mother recently returned to her job as an accountant, works 9 hours a day, and is fatigued when she picks up Phillip at 5:00 PM. Phillip's father travels for his job but is home on weekends to spend time with his family. Although Phillip's mother always believed that Phillip was shy because he was quiet, during the last week at child care he started hitting his peers and becoming loudly vocal at story time. His mother, believing that Phillip's behavior is related to her return to work, feels embarrassed and frustrated by his behavior, especially because she enjoys her new job and the extra income.

- What factors might be contributing to Phillip's changed behavior?
- How might you define Phillip's temperament? Why?
- What discussions might you have with Phillip's parents to help them understand, respond to, and change their son's behavior for

the better?

The preschool child (age 3–6 years) has a more developed body structure, an ability to control and use the body, and a facility with language that more closely resembles that of the adult than that of the toddler. The major psychological thrust of this period of development is mastery of self as an independent human being, with a willingness to extend experiences beyond those of the family. Although historically the end of early childhood in the Western world was marked by entrance into the formalized educational system, increasing numbers of children in the United States begin formalized schooling during their preschool years. Box 19-1: *Healthy People 2020* presents objectives related to this developmental stage (US Department of Health and Human Services, 2011).

Box 19-1

Healthy People 2020

Select National Health-Promotion and Disease-Prevention Objectives for Preschool Children

- Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs.
- (Developmental) Increase the proportion of preschool Early Head Start and Head Start programs that provide health education to prevent health problems in the following areas: unintentional injury; violence; tobacco use and addiction; alcohol and drug use; unhealthy dietary patterns; and inadequate physical activity, dental health, and safety.
- Reduce blood lead levels in children.
- Reduce exposure to selected environmental chemicals in the population, as measured by blood and urine concentrations of the

substances or their metabolites.

- (Developmental) Increase the proportion of children who are ready for school in all five domains of healthy development: physical development, social-emotional development, approaches to learning, language, and cognitive development.
- Increase the proportion of parents who use positive parenting and communicate with their physicians or other health care professionals about positive parenting.
- (Developmental) Decrease the proportion of children who have poor quality of sleep.
- Reduce infections caused by key pathogens transmitted commonly through food (postdiarrheal hemolytic-uremic syndrome in children younger than 5 years).
- Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children.
- Reduce fatal and nonfatal injuries.
- Reduce child maltreatment deaths.
- Increase the proportion of children with special health care needs who receive their care in family-centered, comprehensive, coordinated systems.
- Increase the number of states with nutrition standards for foods and beverages provided to preschool children in child care.
- (Developmental) Prevent inappropriate weight gain in youths and adults (children aged 2–5 years).
- Reduce iron deficiency among young children and females of childbearing age (children aged 1–2 years).

- Reduce the proportion of young children aged 3 to 5 years with experience of dental caries in their primary teeth.
- Increase the proportion of children and adolescents aged 2 years through 12th grade who view television, watch videos, or play video games for no more than 2 hours a day (children aged 2–5 years).
- Reduce asthma deaths (children and adults younger than 35 years).
- Reduce the proportion of nonsmokers exposed to secondhand smoke (children aged 3–11 years).
- Increase the proportion of preschool children aged 5 years or younger who receive vision screening.

Biology and Genetics

The protuberant abdomen of the toddler disappears during the preschool years as the pelvis begins to straighten and the abdominal muscles develop. The hips gradually rotate inward, replacing out-toeing with straight or slight in-toeing. Mild in-toeing (metatarsus adductus) may remain during the preschool years, but anything beyond a mild level should be investigated and treated.

Growth rates remain steady from age 3 to 6 years. Average preschoolers gain approximately 2 kg (4 pounds) of body weight and 7 cm (2 inches) of height each year, whereas head circumference increases by less than 2 cm during the entire preschool period. During early childhood, skin matures in its ability to protect the child from outer invasion and loss of fluids. The skin's capacity to localize infection increases but remains less than that of a mature person. Negligible secretion of sebum makes the skin fairly dry. **Eccrine sweat gland function,** part of the body's heat-regulation mechanism, gradually matures, but the quantity of eccrine sweat produced in response to heat or emotion remains minimal. Apocrine sweat glands, located primarily in the axillae, areolas of the breast, and the anal area, remain nonsecretory during this period.

The kidneys reach full functional maturity by the end of infancy and early toddlerhood, with only their size changing during the preschool years. By the end of the preschool years, urine excretion ranges from 650 to 1000 mL (19–30 ounces). Under normal homeostatic conditions, the preschooler's renal system conserves water and concentrates urine on a level that approximates adult abilities. Under conditions of stress, however, the kidneys lack the ability to respond fully and to maintain **homeostasis** when compared with the more rapid response of the adult renal system.

Growth of gastrointestinal organs continues through the preschool years without functional changes. Children achieve full voluntary control of elimination. **Lactose intolerance,** intolerance to milk products manifested by diarrhea, often appears during the preschool

years. This condition, more common in black, Asian American, and Native American children, can be managed successfully by elimination of lactose from the diet.

Lung capacity continues to increase, with a gradual decrease in respiratory rate. Preschoolers make better decisions than toddlers about objects they place in their mouths, resulting in fewer instances of choking and obstruction. A gradual increase in the size and shape of the ears coincides with decreases in the incidence of **otitis media** (middle ear infection). Tonsils and adenoids are large compared with their throat, which may contribute to noisy breathing and upper respiratory tract infection in preschoolers.

The cardiovascular system enlarges in proportion to general body growth. Heart rate for preschoolers ranges from 40 to 70 beats per minute, with a mean blood pressure of 100/60 mmHg. Early hypertension develops in some children during the preschool years; therefore routine measurement of blood pressure is indicated, particularly in children with a strong family history of hypertension (see Chapter 20). Preschool children maintain adequate hemoglobin levels when dietary intake is sufficient. Bone marrow of the ribs, the sternum, and the vertebrae become fully established as primary sites for red blood cell formation. The liver and spleen continue to form erythrocytes and granulocytes.

The immune system continues to develop. Preschoolers boost their immune response to common pathogens as exposure occurs. Group activities, such as joining preschool or play groups, increase exposure and subsequently escalate the incidence of common contagious illnesses during the time of exposure, regardless of the child's age. Initial encounters with such group activities usually result in increases in illness. Later these children may be less prone to common contagious diseases because of their early exposure to infectious illnesses and their consequent immunity.

Primary teeth finish erupting by late toddler or early preschool years. Initial permanent teeth generally erupt toward the end of the preschool period. Permanent teeth tend to erupt approximately 6 months earlier in girls than in boys. Older preschoolers usually take

responsibility for dental hygiene, although all children need gentle guidance about proper brushing and appropriate nutritional intake for healthy teeth. Parents should continue to assist with brushing and supervise flossing and fluoride intake. Risk of fluorosis exists in children younger than 8 years and is influenced by both the dose and the frequency of exposure to fluoride during tooth development (Wright et al., 2014). Balancing this risk of opacity against the prevention of caries involves assessment of the amounts of fluoride the child receives from various sources. Fluoride sources include public water supply in some regions, foods, drinks, fluoride supplements, and accidentally swallowed toothpaste (Clifton, 2014). Because the preschool period is an age of caries formation, regular dental checkups are essential. The American Academy of Pediatrics recommends use of a smear (the size of a grain of rice) of toothpaste up to age 3 years. After the third birthday, a pea-sized amount may be used. Fluoride varnish is recommended in the primary care setting every 3 to 6 months starting at tooth emergence. Over-the-counter fluoride rinse is not recommended for children younger than 6 years because of the risk of their swallowing higher-than-recommended levels of fluoride (Clark & Slayton, 2014). Nurses assess whether the child is receiving preventive dental care. Parents should be encouraged to begin or maintain this care. Suggestions for promoting good oral hygiene as part of general health-promotion teaching can be found in Chapter 20.

Musculoskeletal and neurological development reaches a level that allows seemingly effortless walking, running, and climbing. Older preschoolers' ability to copy figures and draw recognizable pictures indicates their advancing fine motor abilities, and they are eager to demonstrate these skills to others. Practice, increases in muscle size, continuing associations among existing neural pathways, and the establishment of new pathways for already accomplished tasks are a few of the many complex factors that contribute to the advances in neurological function observed during early childhood. These advances in fine motor, gross motor, cognitive, communicative, and social-emotional skills are outlined in Table 19-1.

TABLE 19-1

GROWTH AND DEVELOPMENT
Developmental and Behavioral Milestones for Preschool Children

Age (yr)	Expectations
3	At this age, the typical child: • Builds a tower of six to eight cubes • Throws ball overhand, rides tricycle, walks up stairs alternating feet • Has self-care skills (self-feeding, self-dressing) • Knows own name, age, and sex • May comprehend cold, tired, hungry; may understand the prepositions over and under; differentiates bigger and smaller; can convey the use of scissors, key, and pencil • Copies a circle, draws a person with two body parts (head and one other part) • Engages in imaginative play that becomes more elaborate with specific themes or story lines demonstrated; enjoys interactive play • Speech is understandable 75% of the time; names a friend; carries a conversation with two or three sentences spoken together • Is toilet trained during the daytime for both bowel and bladder
4	At this age, the typical child: • Alternates feet when descending stairs; jumps forward; hops on one foot, and can stand on 1 foot for up to 5 sec • Using overhand toss can hit target from 5 feet • Builds a tower of eight blocks • Copies a cross • Holds and uses a pencil with good control • Cuts paper into two pieces • Pours, cuts, and mashes own food • Brushes own teeth • Dresses self, including buttons • Gives first and last name • Engages in conversational give-and-take • Knows what to do if cold, tired, or hungry • Sings a song or says a poem from memory • Talks about daily experiences and things that are used at home (food, appliances) • Can name three or four primary colors • Is aware of sex (of self and others) • Plays board/card games • Draws a person with three parts • Tells you what he/she thinks is going to happen next in a book • Describes features of himself, including sex, age, interests, and strengths • Engages in fantasy play
5	At this age, the typical child: • May be able to skip; can walk on tiptoes; makes broad jumps • Folds paper parallel; colors between vertical lines • Ties a knot, has mature pencil grasp • Names four or five colors and can identify coins • Tells a simple story and knows several nursery rhymes • Dresses and undresses without supervision • Prints some letters and numbers, is able to copy square and triangle from an illustration • Draws a person with at least six body parts • Begins to understand right and wrong, fair and unfair • Engages in dramatic make-believe and dress-up play during which the child assumes a specific role; engages in domestic role-playing and dressing up

	• Enjoys the companionship of other children; plays cooperatively • Has good articulation, uses appropriate tenses and pronouns • Can count to 10
6	At this age, the typical child: • Bounces a ball four to six times; throws and catches • Skates • Rides a bicycle • Ties shoelaces • Counts up to 10; prints own first name; prints numbers up to 10 • Understands right from left • Draws a person with six body parts, with the figure depicted a person wearing clothing

Modified from American Academy of Pediatrics. (n.d.). Bright Futures. http://brightfutures.aap.org/.

Gender

Boys tend to experience more childhood illnesses than do girls from 3 to 6 years of age (see Chapter 18). Preschoolers are more aware of their sexual identity than are toddlers and may imitate societal stereotypes more closely. Traditionally boys have been encouraged to take more risks than girls have been and they have more accidents than do preschool girls, who may have been encouraged to choose more sedentary activities. For example, in their study of 476 preschool children (50% male), Brown and colleagues (2009) found that 3-year-old boys were more active than 3-year-old girls. In today's society, boys and girls have more opportunities to choose the same activities, but preschool activities can also be geared to be gender neutral to encourage more female participation. Gender-neutral activities such as tag, hide and seek, kick ball, duck duck goose, red rover, and obstacle courses may encourage physical activity for both boys and girls. It will be interesting to observe whether societal changes or preschool policy changes will reflect accident or obesity statistics in the future.

Race

Race, with its related economic and cultural issues, can influence health care practices at this age, as is the case at all ages. Cultural preferences and economic issues therefore influence the environments and other health-promoting behaviors, such as nutrition and

recreation (Brown et al., 2009; Division of Adolescent and School Health, National Center for Chronic Disease Prevention and Health Promotion, 2011; Dogra et al., 2010; Lee & Im, 2010).

Genetics

The signs and symptoms of most genetic problems appear during infancy or the toddler years, whereas other genetic problems will be noted during adolescence. Those most likely to appear during the preschool years are cystic fibrosis, Duchenne muscular dystrophy, fragile X syndrome, Williams syndrome, and autism, which is generally considered a genetic disorder with a high degree (90%) of heritability (Freitag et al., 2010). These disorders, characterized by aberrant social interaction, communication, and stereotyped patterns of behavior, affect 0.5% to 1.0% of the population and are often diagnosed or suspected in the preschool years, when social interaction plays a larger role in development (Boyd et al., 2010; Freitag et al., 2010).

Genetic conditions (Box 19-2: Genomics) diagnosed early in life affect the child's health, and nursing strategies focus on continuing parent education, assessing the child's development (including complications), and providing interventions to support family coping (Boyd et al., 2010).

Box 19-2

Genomics

The field of cystic fibrosis (CF) has benefited from developments and advancements in genomics in terms of detection, understanding, and monitoring of the disease state. Infants with CF are structurally normal at birth; however, they have an inability to control bacterial infection, which plays a key role in early CF lung disease pathogenesis. Research and application of novel molecular techniques to explore the human microbiome has helped develop an understanding of CF airway microbiology and how it differs from that of those without the disease. The drug ivacaftor was approved

by the Food and Drug Administration in 2012 for the treatment of CF patients carrying at least one copy of the G551D mutation in the cystic fibrosis transmembrane conductance regulator gene (*CFTR*). CF is caused by one of several defects in cystic fibrosis transmembrane conductance regulator, which regulates fluid flow within cells and affects the components of sweat, digestive fluids, and mucus. The G551D mutation, in particular, is characterized by a dysfunctional cystic fibrosis transmembrane conductance regulator that cannot transport chloride through the ion channel. Ivacaftor increases the transport of chloride through the ion channel by binding, and thus for the first time is able to treat the underlying cause of CF instead of its symptoms.

Gordon's Functional Health Patterns

Health Perception–Health Management Pattern

Preschoolers have a fairly accurate perception of the external parts of their own bodies based on what they can see and do; they may be extremely curious about the body of a member of the opposite sex. Their concepts of what is inside the body and how its internal functions operate are vague and inaccurate. Preschoolers view the internal part of the body as hollow. Most preschoolers can name one or two items inside the body (blood, bones). Many of their questions involve body functions. Anxiety surrounding the body and fear of mutilation and death pervade the children's concerns. Their size as compared with that of adults produces a sense of vulnerability and fear of loss of control (Price & Gwinn, 2008).

By age 4 or 5 years, children have amassed their beliefs about health from the family. They begin to understand that they play a role in their own health. The preschooler often becomes upset over minor injuries. Pain or illness may be viewed as a punishment. The preschooler's declaration "If you don't put your seat belt on you will get in an accident" is a statement that reflects the idea of expected immediate and absolute cause and effect. The preschooler cannot conceive that the purpose of the seat belt is to prevent injury in the event of an accident, not prevention of the accident itself.

Although preschoolers are not completely responsible for their own health management, they certainly contribute by brushing their teeth, taking medication, wearing appropriate clothing for inclement weather, and performing other actions. Preschoolers' memory of these activities can be sporadic, but they are at least beginning to be their own health care agents (Yoo et al., 2010).

Reinforcement of health-promotion activities, which occurs in the home and child care environments, helps to instill behaviors that affect self-esteem, safety, and an individual's overall balance with life. For example, family support for active lifestyles provides one way for parents to assume a positive role to model for children (Division of

Adolescent and School Health, National Center for Chronic Disease Prevention and Health Promotion, 2011). The National Association of Pediatric Nurse Practitioners has designed Healthy Eating and Activity Together resources to engage families in health-promoting behaviors (Gance-Cleveland et al., 2009).

In addition, the preschool environment influences health-promotion activities for many children in this age group. For example, when Brown and colleagues (2009) directly observed children in 20 preschool settings, they demonstrated that aspects of the preschool environment affected children's activity levels. Preschool settings with more resources also offered a greater variety of activities. Even these preschools with more resources were well below the physical activity time recommended (120 minutes per day) by the National Association for Sport and Physical Education (2009). Their findings provide further support for those of Bower and colleagues (2008), who demonstrated that in preschool settings, children participated in physical activity for approximately 80 minutes more in settings with more resources than children in settings with fewer resources. These findings indicate a need for health-promotion advocacy and policy development focused on the environment. Many community bookstores carry health-promotion–focused books appropriate to the preschool population; these references provide information for discussion among parents, caregivers, and children on the importance of healthy behaviors for success in life.

Nutritional-Metabolic Pattern

Establishing healthful nutritional and physical activity behaviors begins during childhood. Children should eat a variety of foods, with at least five servings of fruits and vegetables per day. Children aged 3 to 5 years old should receive 1200 to 1600 calories per day depending on their activity level and sex (US Department of Agriculture & US Department of Health and Human Services, 2010). Preschool children should consume approximately half of their diet in carbohydrates, with the other half consisting of protein (≈5–20%) and fat (≈20–35%) (US Department of Agriculture & US Department of Health and

Human Services, 2010). With more than half of the preschool diet consisting of carbohydrates, whole grains and other complex carbohydrates should be plentiful to attain a total fiber intake of 20 to 25 g per day (US Department of Agriculture & US Department of Health and Human Services, 2010). Fat requirements in preschool children are higher than those for older children, but fat consumption should consist primarily of unsaturated fat, with saturated fat, trans fatty acids, and cholesterol intake as low as possible. Guidance for these recommendations along with the types and amounts of foods is depicted in the system called MyPlate (http://www.choosemyplate.gov/). A child-friendly version of MyPlate addresses the special needs of children 6 to 11 years old (Nappo-Dattoma, 2011). Preschoolers need approximately 90 kcal/kg of body weight per day for health maintenance, activity, and growth. MyPlate is used as a guideline for preschool nutrient consumption (Hockenberry & Wilson, 2015). However, because of the unique dietary patterns of preschoolers, the food intake is variable.

Specific issues that impact the preschool age include bone growth, iron-deficiency anemia, milk intake, salt intake, sugar intake, and dentition. For bone growth, children aged 1 to 8 years require a calcium intake of approximately 700 to 1000 mg. Although the frequency of iron-deficiency anemia is decreasing generally, it is more prevalent in vulnerable populations (McCann & Ames, 2007). The studies that have been conducted, although small in number, support the idea that iron deficiency results in behavioral and cognitive deficits (McCann & Ames, 2007). Salt and sugar intake should be moderate. The contribution of sugar intake to caries development is well established. For example, Warren and colleagues (2009) examined factors associated with carcinogenicity in 128 children. Their study suggests that sweetened beverages, in particular, are associated with the development of caries.

Nutrition and dentition impact health at all ages. Pain from dental caries, infection, and poorly maintained teeth affects appetite and chewing ability, with a subsequent impact on future nutritional status. The frequency of dental caries in children has declined dramatically in

recent years because of preventive measures, such as use of fluoride toothpaste, fluoridation of community water supplies, implementation of sound dietary practices, and use of dental sealants. Children from low-income families carry the bulk of the burden of these dental caries (Nappo-Dattoma, 2011). Oral health promotion involves self-care and population-based initiatives, along with professional care. The adequacy of professional dental care differs significantly by age, race, educational level, family income, and dental status (Nappo-Dattoma, 2011). Nurses interface with families in a variety of these settings and are therefore in an ideal position to impact dental health promotion.

As early childhood progresses, intense food preferences emerge. This behavior is a natural outgrowth of the increased physical capacity to react to the taste and textures of foods and the realization that expressing an opinion about food is a way to control the environment. Older preschoolers frequently refuse to try new foods. The favorite foods for this age are meat, cereal grains, baked products, fruits, and sweets. Selecting finger foods that facilitate independence helps the preschooler learn to eat without assistance. Examples of appropriate nutritional foods include cheese, crackers, small pieces of meat, and celery stuffed with cheese or peanut butter. Parents' support for food choices has been demonstrated to be an effective strategy to promote healthy food choices in this age group (Marshall et al., 2011). Parents should provide nutritious foods, avoiding salty and sweet foods. Parents should encourage good nutritional habits to help establish healthy eating behaviors. Increased consumption of fats and processed foods along with diminished physical activity has contributed to a significant increase in the frequency of obesity and type 2 diabetes in children and adolescents (Liou et al., 2010; US Department of Agriculture & US Department of Health and Human Services, 2010; US Department of Health and Human Services, 2011). Family tolerance for individual food preferences differs, and children differ in their tendency to develop strong likes and dislikes. When families reach extreme differences over food preferences, major conflicts may arise, requiring insightful counseling to achieve a

mutually satisfying solution. For example, some families may institute a “take a little taste before your refuse” standard for foods at the preschool age. Nurses collaborate with families to discover comfortable approaches to maintain nutritional adequacy of foods that children prefer. Community nurses use a variety of approaches and recognize the wide range of possibilities that exist for families of differing cultures.

Preschoolers begin to eat meals away from home more often than toddlers. Minimal standards require licensed child care centers and preschools to serve foods using recommended dietary allowances of basic nutrients. Parents should communicate regularly with agency personnel about foods eaten at home and away from home to provide healthy food variety. Preschoolers in group settings learn both positive and negative eating habits and food preferences from care providers and other children. School settings are ideal for community health nurses to impact the nutritional patterns of the preschool child (Water, 2011). Communication about nutritional intake habits reinforces positive behaviors and discourages negative habits at home (Box 19-3: Innovative Practice).

Box 19-3

Innovative Practice

Healthy Start

Risk factors for cardiovascular diseases are prevalent by 3 years of age, the most common of which are hypercholesterolemia and obesity. Healthy Start, a project located in Valhalla, New York, sponsored by the Child Health Foundation and the American Health Foundation, is a 3-year demonstration and research program to evaluate the effectiveness of interventions for reducing cardiovascular risk factors in preschool centers. Two interventions are recommended. The first is that the preschool food service be designed to reduce the total fat in the preschooler's meals and snacks to less than 30% of calories and to reduce saturated fat to less than 10% of

calories. The second intervention is a comprehensive preschool health-education curriculum, which focuses on nutrition and exercise.

The effectiveness of this program is evaluated with use of many components. Changes in the nutritional behaviors (including dietary intake of school snacks and meals of the preschoolers) are being recorded, as are those with regard to snacks and meals consumed at home. Special attention is being given to the intake of total and saturated fat. Additionally, changes in the health knowledge of preschoolers are being assessed to evaluate the education component. Physical examination data include semiannual assessments of growth and body weight and blood lipid levels.

The specific details of the rationale and methods of the randomized controlled trial studies within the Healthy Start project are described at its website: http://www.healthy-start.com.

Preschoolers struggle with the intricacies of using utensils. In the later years of the preschool period, children attain skill with spoons, demonstrate fair proficiency with forks, and manage knives for spreading soft foods on bread or crackers. Most preschool children, however, need help cutting meat and pouring liquids from large, heavy containers. Preschoolers enjoy helping to prepare family meals

and may be capable of simple tasks, such as washing fruits and vegetables. Involving young children in meal preparation teaches them about healthy nutrition. Sharing important family functions nurtures self-esteem and a sense of value.

The prevalence of food allergy in children in the United States continues to increase, affecting up to 8% of children. Approximately 1 million preschool children are affected, and one-third of these children have the potential for a severe reaction (Fleischer et al., 2012; Gupta et al., 2011). Most allergies develop before the age of 2 years. The foods most likely to cause allergic reactions in the preschool age group include milk, eggs, and peanuts (Fleischer et al., 2012; Gupta et al., 2011). Reactions to peanuts tend to decrease over time; however, children who experience peanut allergy should avoid allergens, and their parents should receive written emergency plans along with instructions for epinephrine injection (Fleischer et al., 2012). Clear food labeling and education are essential for prevention of allergic reactions. Many preschools have banned foods such as peanut products as a precautionary measure. Parents may need help identifying potential hazardous situations and communicating their child's needs to agency personnel. A food allergy action plan that includes a written emergency plan should be developed for parents to use to facilitate communication regarding the child's allergies. Educational resources are available at http://www.cofargroup.org/.

Elimination Pattern

Toilet training is an important milestone in child development (Kaerts et al., 2012). Older preschool children are capable of and responsible for independent toileting. Their verbal skills have developed to better communicate their needs, they begin to insist on performing independently, and they are proud of their accomplishments (Kaerts et al., 2012). These developmental achievements provide additional signs for independence with elimination patterns. They may forget to flush the toilet or wash their hands when they are rushed, but they have the physical ability to perform the skills. Preschoolers should not be teased or punished when they are unable to perform

independently. If their clothing becomes soiled, they should be responsible for changing their clothes and reminded gently and encouragingly of ways to avoid problems in the future. (Enuresis and encopresis are discussed in Chapter 20.)

Activity-Exercise Pattern

Play continues to be the primary activity for preschoolers as well as for toddlers; however, preschoolers explore intently and demonstrate increased coordination and confidence with motor activities. They venture farther from home than toddlers. Many activities involve other children (Figure 19-1) and involve modeling behavior. Particularly in group care settings, children should be monitored for safe activities that enhance gross and fine motor skills while creating fun in movement.

FIGURE 19-1 Preschool children can enjoy their pet even at bath time.

Most 4-year-old children separate easily from their parents, play simple interactive games, dress themselves, copy a number of basic geometrical figures well, and draw recognizable people. Preschoolers

enjoy using language skills to tell stories and ask questions. Their physical abilities include balancing on one foot, jumping, and running (Driscoll & Nagel, 2008). Generally, preschoolers appreciate an audience, enjoy practicing new skills, and demonstrate mastered skills to others. Play constitutes an important role in preschoolers' social and psychological development. Play offers a vehicle that allows them to explore while experimenting with who they are, who they might become, and how they relate to others socially. The drama of play allows preschoolers to view themselves from another perspective. Play often reveals the child's reality and complex perception of the world.

Children mimic the behavior of people familiar to them, expanding their representation beyond self and rehearsing what has been demonstrated to them as appropriate behavior (Driscoll & Nagel, 2008). Young children seldom assume the role of a younger child or infant while playing. They usually assume adult roles and use a doll for the younger child. Through play preschoolers learn to exert control over their own behavior. Assuming an adult role in play allows children to consciously adopt more mature behaviors. Patterns of behavior used in play can be transferred to actual situations. For example, children who express their anger in a play situation aggressively by vocalizing their distress, scolding the offending party, or using withdrawal of attention are likely to respond with aggression or tantrum behavior when facing frustration or anger in real-life situations. Observing children at play, as seen by the study group Brown and colleagues (2009) used in their research, reveals natural physical capacities of children better than observation in an examination or testing environment and provides further evidence of the child's social and inner development for use by practitioners in the field.

Observing symbolic play and imitation play in peer groups helps nurses assess social competency as their perceptions unfold (Driscoll & Nagel, 2008). At first the new child in a peer group may be expected to stand back and observe other children before manipulating a toy. Preschool children engage in more interactive play, particularly

dramatic play, than at any other age. Two or more children may become involved in an imaginary plot, especially when toys and equipment support a particular scenario, such as toy kitchen equipment. Patterns emerge in the interactive processes of play: initiating, deciding with whom to play, play themes/roles/rules, and finally enactment or collaborative pretending. These patterns provide opportunities for support to facilitate play initiation and collaborative play (Driscoll & Nagel, 2008). Much of the preschooler's play involves fantasy. The young child frequently invents an imaginary companion who plays, eats, and sleeps with the child. The section entitled cognitive-perceptual pattern addresses more fully the aspects of fantasy during the preschool stage; however, the goal of symbolic or pretend play is to derive meaning from their play experience using their knowledge and skills acquired. The play is a way to integrate previously learned ideas and skills (Driscoll & Nagel, 2008).

Most preschoolers spend some time in a group setting each week. Ground rules at these facilities govern sharing, **quiet** times, and group activities. Although time orientation remains incompletely developed in preschoolers, they have an idea about past and future. They enjoy planning activities with their parents for the future. Visiting the library to review books about wild animals, packing lunches, and choosing what clothes to wear may preface a trip to the zoo.

The preschooler regulates body activities with more purpose and copes with limit setting better than the toddler, but has much energy and requires outlets for this energy during the day. The young child requires physical activity for energy expenditure. Physical activity, for the developing child, may be more appropriately described as either locomotor play or active play (Pellegrini & Smith, 1998). Active play increases from the toddler to the preschool period, and then declines by approximately 10% for each advancing year of age (Hinkley et al., 2012). Hinkley and colleagues (2012) concluded that efforts to promote children's physical activity should seek to influence children's preference for physical activity, parent rules, and sex-specific strategies. Becker and colleagues (2014) investigated whether active play during recess was associated with self-regulation and

academic achievement in prekindergarten children. The results revealed that higher active play was associated with better self-regulation and higher scores on early reading and math assessments. Nurses should encourage parents to engage the preschool child in active, locomotor, and rough-and-tumble play. Parents and child care directors/school administrators should also encourage physical activity and work together to overcome perceived barriers that might limit the young child's ability to access physical activity (Gagne & Harnois, 2014).

Although this age group needs physical activity, many preschoolers spend long periods each day watching television, watching videos, and playing electronic games. Occasionally parents use the electronic diversions inappropriately to entertain the child. Although some excellent television, video, and electronic game programming is available for preschoolers, many electronic entertainment options focus on adult themes and violence. Many experts agree that television, videos, and electronic games disengage the child's mind and support less learning (Frost et al., 2008) (see Chapter 20). Parents should remember that preschoolers who rely on television, videos, and electronic games do not have enough life experiences to interpret many of the issues presented in adult shows (violence, interpersonal relationships, moral decisions); might be missing opportunities for interacting with other children or adults and other opportunities for active learning; and cannot judge which shows are appropriate for them. In addition, these electronic activities usually offer sedentary recreation, hindering the development of an active healthy lifestyle. Parents should choose which electronic devices and activities are appropriate for their child, limiting time and promoting physical activity in lieu of sedentary play. Furthermore, taking time to share activities provides the child with an opportunity for discussion and for the child to ask questions (Frost et al., 2008). Nurses should explain to parents and preschoolers the relationship between watching television/screen time and lack of physical activity that leads to health problems such as obesity (Frost et al., 2008). Family support for engaging in physical activity has been shown to affect children's

health-promoting behaviors. In a study of 93 children and their parents, Marshall and colleagues (2011) demonstrated that parental influence shaped children's physical activity and nutritional health-promoting behaviors. The literature review by Kornides and colleagues (2011) also describes factors that influence overweight in Latino children. Their review of 24 studies revealed that parental body mass index (BMI) provided the strongest predictor of BMI in Latino children.

Gordon's health promotion–health maintenance, nutritional-metabolic, and activity-exercise patterns clearly overlap and should be considered together during the assessment phase so as to plan and intervene successfully (Marshall et al., 2011). Resources for these patterns may be used together to provide optimal health promotion. Physical activity in the preschool child is not typically structured exercises. Children do not usually need formal muscle-strengthening programs, such as lifting weights. Younger children usually strengthen their muscles through play activities such as climbing on a jungle gym or trees, riding a tricycle, playing ball, and running/jumping with parents and peers.

Sleep-Rest Pattern

Most preschoolers sleep from 8 to 12 hours during the night, with wide variation among children (Hoban, 2010). Many children do not receive the recommended number of sleep hours, and sleep problems in preschool children commonly occur (Vriend & Corkum, 2011). For many older preschoolers, a nap is not necessary. By the age of 5 years, most preschoolers no longer regularly nap during the day (National Sleep Foundation, 2011). Quiet time provides a welcome respite for the parent, along with a chance for the active preschooler to relax before afternoon activities. Many child care/preschool environments routinely provide rest periods, enhancing rest and relaxation with soft music and a story. An afternoon rest also gives the young child energy for the evening routine, when family members have other duties beyond work and school.

Sleep time habits, falling asleep, and waking up during the night

present challenges for families with preschool children (National Sleep Foundation, 2011). The preschooler's expanded imaginative play and increased physical activity during the day may provoke nighttime fears, nightmares, sleepwalking, and sleep terrors, which are at a peak during this stage of development (National Sleep Foundation, 2011).

Bedtime Ritual

Preschoolers usually require a ritual of activities at bedtime to move from playing and being with others to being alone and falling asleep. These children prolong bedtime routines more often than the toddler. They insist on sleeping with the light on, take a treasured object to bed, request parental attention after being told good night, and experience delays falling asleep. The bedtime ritual generally lasts 30 minutes or longer. Parents honor reasonable rituals, but repeated requests for attention afterward are handled firmly and consistently. Consistency with the routine helps to ameliorate bedtime battles (Hoban, 2010). Vigorous resistance to bedtime challenges parents more during the preschool period than at any other developmental stage. Behavioral insomnia in children occurs when this resistance is associated with a negative association with sleep (Vriend & Corkum, 2011). Preschoolers learn to use the behaviors that meet their needs and control the family regardless of the disruption created.

Nursing Interventions

When a demanding bedtime behavior extends beyond 1 year or an episode persists longer than 1 hour, the nurse explores the family situation. A comprehensive assessment in this case includes the following elements:

- Description of early episodes
- The manner in which these early episodes were managed and the progression of events since then
- Current bedtime behaviors of the child and siblings
- Identification of parental temperament and the resulting responses

of the parents and family members

- Feelings of the parents and child about each other and about the bedtime situation
- Stressful events and changes that have occurred in the past several years
- Behavior of the child at other times of the day
- Parents' thoughts about the reasons why these episodes continue
- Parents' ideas about strategies to use now

The nurse observes interactions within the family. A home visit at mealtime provides an excellent method to observe active interaction. In the office or clinic setting the nurse can ask a parent to teach the child a task or give directions. The nurse remains as unobtrusive as possible while observing the interaction. The first-hand observation of parent-child interaction, along with the detailed history, usually provides the nurse with adequate baseline information to decide whether to manage the situation in the primary care setting or refer the family to a child behavior specialist. Sharing recent literature about management techniques for children with differing temperaments helps families understand more about the behaviors. For example, the findings from a study of more than 1500 children by Prior and colleagues (2011) support that temperament in children may be somewhat modifiable and that parents may consider strategies to influence their preschooler's behavior that focus on their temperament. Research-based strategies should be used to help parents reach their goals related to managing bedtime concerns.

Sleep Disturbances

Night terrors and **nightmares** characterize the nighttime wakening problems that generally occur during the preschool years. Night terrors manifest themselves as frightening dreams that cause the child to sit up in bed, scream, stare at an imaginary object, breathe heavily, perspire, and appear in obvious distress (see Chapter 18). The child, not fully awake, may be inconsolable for 10 minutes or more, before

he or she relaxes and returns to a deep sleep. In most cases the child does not recall the dream and in the morning does not remember the incident (Hoban, 2010). These night terrors can start at approximately age 2 years but are more common during the preschool years. Night terrors rarely occur in older children and adults, and only approximately 6% of preschool children have them. Night terrors and nightmares trigger apprehension for the parents (Hoban, 2010).

Nightmares (anxiety dreams) are a more common cause of night wakening. Although infants and toddlers likely have nightmares, their limited verbal skills hinder their relating details of the incidents. After age 3 years, nightmares occur frequently. Approximately 20% of the night is spent dreaming. Dreams frighten preschoolers as they connect to the larger world with their active imaginations and fantastic ideas. These children can waken fully and feel fearful and helpless. Usually they provide vivid descriptions at the time, and they frequently remember the event the following morning. Consolation can be given by a parent who sits with the child, listens to descriptions and fears about the dream, and reminds the child that dreaming is natural and sleep will soon return (Hoban, 2010).

Helping children appreciate the meaning of the words *pretend* and *real* facilitates growth during this phase of childhood. When the parent reads a story to the child or the child tells a make-believe tale, the parents can specify that these are "pretend" and did not really happen. The parent relating a true event can say, "This is real." Children differentiate between the two concepts as they develop cognitively.

Recommendations

Parents of a preschooler can benefit from knowing the following facts:

- Bedtime rituals of 30 to 45 minutes are common for preschoolers. These rituals, because of their importance to children, are respected within reasonable limits. Maintaining a regular consistent and relaxing routine facilitates sleep (National Sleep Foundation, 2011).
- Night-wakening events are common during the preschool years. A

consistent sleep environment with the same bed in a room that is cool, quiet, and dark without a television promotes sleep (National Sleep Foundation, 2011). Children who waken at night are reassured and encouraged to return to sleep.

- Parents have clear rules about children sleeping with them if the children will not stay in their own beds.
- Restricting the watching of frightening television shows and the reading of frightening stories and discussing "real" versus "pretend" ideas and stories can help lessen the incidence of nightmares.

Cognitive-Perceptual Pattern

During the preschool years, children cultivate their conceptual and cognitive capacities. The quality of the child's care environment enhances these gains. Family and cultural values influence preschoolers' perceptions and their reaction to events (Gonzalez-Mena, 2012). Internalization of family rules has been associated with social competency in this age group (Kochanska et al., 2010). Preschoolers gradually differentiate today from yesterday and define tomorrow and the future more clearly as concepts of time emerge. The child becomes more oriented in space and develops an awareness of the location of the home within the neighborhood. The child also begins to structure daily activities and to value certain activities, objects, and people above others.

Piaget's Theory

The older toddler enters the first substage of the **preoperational stage** described by Jean Piaget (see Chapter 18). The hallmark of this preconceptual substage includes the ability to function symbolically using language. The preschool child demonstrates increased symbolic functioning during the intuitive substage, from 4 to 7 years of age. The predominant feature of this and the following period is the concrete thought process, as compared with adult abstract thinking. As they experience symbolic mental representations, preschoolers process mental symbols as though they were actually participating in the

event. Adults analyze and synthesize symbolic information without concrete connections between the mental process and the actual event. At this stage, mental abstraction, such as skipping from one part of an operation to another, reversing the operation mentally, or thinking of the whole in relation to the parts, is not feasible.

The **egocentrism** that is characteristic of the preschool years exemplifies this concept of concrete thinking. At this stage, children concentrate solely on their own perspective. They consider only their own personal meanings for symbols. The preschooler wonders why another person fails to follow these idiosyncratic communications.

Furthermore, attention focuses solely on one part of an object without shifting. This behavior, termed **centering** by Piaget, illustrates the child's inability to consider more than one factor at a time when solving simple problems. For example, a child can be given two identical cups containing equal amounts of water and asked which cup contains the greater amount of water. During the preoperational stage, the child responds that they contain the same amount of water. The child is then asked to pour the water from each cup into two different containers (one flat and wide, the other tall and narrow). When asked which container has more water, the child always identifies one. The child usually selects the taller, narrower container with water at the higher height. When the water is again transferred to the identical cups and the experiment is repeated, the child returns to the original conclusion that the amounts are equal.

This experiment also illustrates the trait of **irreversibility.** The child is unable to connect the reversible operation, the transfer of the water back into the original cup, to reach the logical conclusion that the differently shaped containers may hold the same amount of water. The child cannot mentally associate that the transformation from one state to another relates to the shape of the container, not the amount of the water.

Finally, Piaget describes the preoperative stage of thinking as **transductive reasoning.** The child cannot proceed from general to particular **(deduction)** or from particular to general **(induction);** rather, the child moves only from particular to particular in making

associations and solving problems. For example, Piaget relates an association made by one of his children between being hunchbacked and being ill. When a hunchbacked neighbor was unable to visit one day because he had a communicable illness, the child understood that the neighbor was ill. However, when the child was told later that the neighbor was better and that she could go see him, her conclusion was that now his hunched back was straight and well. She thought in terms of the man being well or ill, but she placed the man in one or the other category and assumed that he possessed all the attributes and meanings that she linked symbolically with either trait.

The cognitive development of preschoolers is reflected in their symbolic games, which become significantly more orderly and representative of reality (Box 19-4). They begin to incorporate the reality of the world, as it exists outside the self. They increasingly seek play objects that represent models of authentic objects in their environment (Langevin et al., 2009). Preschoolers progressively imitate more social rules in their play. Social interactive play predominates as the young child develops a more secure sense of self.

Box 19-4

Play as a Method of Learning: Preschool Child

Throughout life, play develops cognitive, affective, and psychomotor skills that are important for the effective performance of life skills. For the preschool child, the following play activities provide the foundation for later competency and socialization-skill refinement:

- Arts and crafts (jewelry making, painting, drawing, ceramics, printmaking)
- Group sports (softball, volleyball, soccer, swimming)
- Skating, skateboarding
- Bicycling

- Puzzles
- Gymnastics
- Games (board, card, knock-knock jokes, computer)
- Secret clubs
- Imaginary play (being in playhouse productions)
- Horseback riding

Preschoolers may have one or more imaginary companions who exist for differing periods. These fantasy companions assume the form of another child, an animal, or some other friendly or fearsome creature. Preschoolers may save special chairs, insist that an extra place be set at the table, and talk at length to this companion. Imaginary companions serve an important function; they are controlled totally by the child and are not a threat. In this way the preschooler practices social interactions, controls a fearsome beast, or blames someone for naughty behavior without fear of being scolded, shame, or attack. Imaginary companions do and say only what the child wills.

Vision

Vision capabilities, which are well developed by 2 years of age, continue to undergo refinement during the early childhood period. By approximately age 6 years, the child should approach a 20/20 visual acuity level. The possibility of developing **amblyopia** decreases; it appears most frequently during infancy through approximately the fourth year (see Chapter 18). Depth perception and color vision become fully established, and the child recognizes subtle differences in color shading by the sixth year. Maximal visual capability is usually achieved by the end of the preschool years.

Visual capacity throughout the rest of life deteriorates rather than

improves. This phenomenon relates partly to changes in the refractive power of the lens and developmental changes that occur in the shape of the eyeball. In the normal sequence of growth, the eyeball becomes increasingly spherical, losing the short shape typical of infancy and progressing to the point at which light converges accurately on the surface of the retina. This change occurs at approximately 6 years of age. When this change occurs before the sixth year, growth continues past the point of ideal light conversion, the eyeball lengthens, and the child may develop early **myopic vision,** which will progress with age. Glasses are always indicated for the child who develops myopia before approximately age 8 years.

Early detection requires regular screening with standardized tests such as the Denver Eye Screening Test or the Snellen Screening Test. The Snellen Screening Test, when administered under standardized procedures, has the advantage of rendering a reliable estimate of actual visual acuity (Hockenberry & Wilson, 2015). The child must be able to understand the test requirements of either pointing in the direction of the *E* or naming the letters. The Denver Eye Screening Test was designed for preschool children and includes detection of the commonly occurring visual problems, such as **refractive errors, strabismus** (crossing of the eyes), and amblyopia.

The Prevent Blindness organization recommends regular vision screening of children by health care providers, educators, or public health programs (Prevent Blindness, 2017). In fact, they recommend that parents not take on the role of vision screener. Children who do not pass a vision screen should be taken to an optometrist or ophthalmologist for examination. The pupillary light reflex provides a screening approach for **heterotropia,** a condition in which the child's eyes do not focus together to transmit effective, coordinated binocular vision. When the child has heterotropia, the light from a penlight held approximately 20 inches from the eyes reflects off the pupil slightly off center. Consistent and observable strabismus may be noted. The cover test provides further evidence of a tendency for the child's eyes to cross, known as **heterophoria.** The child focuses on a spot 14 inches away, then 20 feet away. As the child gazes at the designated spot, one

eye is covered completely for several seconds (the eye and eyelashes must not be touched), and then the cover is removed abruptly. If the covered eye moves from the line of vision of the uncovered eye, that eye has a tendency toward muscle imbalance and must be evaluated further.

Color blindness presents a particular problem for younger children because many cues encountered at school depend on the child's ability to distinguish colors. With early detection the child is able to receive assistance to interpret visual cues, thus minimizing the disadvantage of being color blind. The nurse screens the child for certain types of color discrimination difficulties by asking the child to respond to various colors in the environment; however, accurate testing for all types of color blindness requires a specialized tool, such as the **Ishihara test,** which uses a series of cards with color-tinted letters and figures.

Preschoolers may be aware of some discomfort or limitations with vision. The nurse gathers the history from the parents, including the questions listed in the Vision section in Chapter 18, about signs of eye problems.

The preschooler is asked questions to elicit information about the following symptoms:

- Itching, burning, or “scratchy” eyes
- Poor vision
- Dizziness, headaches, or nausea after close eye work
- Blurred or double vision

Hearing

During the preschool years, hearing develops to the level of an adult, when the ability to attend to and interpret what is heard becomes more refined. The 4-year-old preschooler begins to discriminate among remarkably similar speech sounds, such as the difference between sounds made with “f” and “th” or “f” and “s.” It is generally accepted that the hearing ability of preschoolers can be hindered by repeated middle ear infections (otitis media). Otitis media with

effusion can occasionally result in temporary hearing loss. Parents who notice language delays because of ear infections should be referred to their health care provider for appropriate follow-up care for their children (Hockenberry & Wilson, 2015). Parental reports of difficulty should be taken seriously. Clear evidence supports that effective newborn hearing screening programs correct problems early and often correct developmental delay (Houston et al., 2011). The most effective programs have rigorous evaluation of their policies, procedures, processes, and outcomes (Houston et al., 2011; Yoshinaga-Itano, 2011).

Audiometric methods most accurately measure the child's ability to hear. Preschool children possess the developmental capability to have standard audiometric tests performed on them. The child can follow directions by this age, and most preschoolers enjoy demonstrating their abilities and cooperate easily during vision and hearing screening examinations (Hockenberry & Wilson, 2015). Refractive error can be significant in the preschool child. The prevalence of refractive errors (5–7%) and amblyopia (2–4%) in preschool children places vision loss as an important public health concern; however, some screening tests reveal only refractive errors (O'Donoghue et al., 2012). Children younger than 7 years with amblyopia demonstrate significant improvement in vision when treated, providing a rationale for screening and early recognition programs. The American Academy of Pediatrics on-line resources supply information for nurses and families and can be accessed at http://www.healthychildren.org.

To ensure success, the nurse encourages a positive experience by adhering to the following points:

- Use equipment skillfully.
- Use age-appropriate language. Avoid the word test to limit anxiety or fear of failure.
- Encourage the child to ask questions and scrutinize the equipment.
- Perform screening before other intrusive or painful procedures.
- Perform screening in a quiet, private area without distractions.

- Praise the child for cooperating.
- Allow rest periods when the child becomes distracted or tired.
- Discuss results with the child in age-appropriate language.

Sensory Perception

Sensory abilities contribute to preschoolers' skill to perceive and interact with the world. Both sensory acuity and sensory perceptual abilities mature during the preschool years. The nature of the visual stimulus determines the response. Preschoolers respond powerfully to visual illusions and have difficulty discriminating right and left mirror images. Confusion commonly occurs with the letters “b,” “d,” “p,” and “q.”

Language

Cognitive and sensory abilities contribute to preschool language development. Toward the end of the preschool period, **expressive language** rivals that of an adult except for minor deficiencies in refinement, vocabulary, and structure. Language ability depends on aptitude, opportunities to use language, the quality and quantity of language used at home, and the range of experiences. Regardless of expressive capacity, the child develops **receptive language** during the preschool years that provides a vital foundation for later communication. Throughout early childhood, receptive capacity exceeds expressive capacity. Children comprehend meanings of words and phrases not contained in their expressive vocabulary. Associations between concepts materialize, although the child lacks the ability to explain these concepts. Table 19-2 outlines the receptive and expressive language skills of preschoolers.

TABLE 19-2

GROWTH AND DEVELOPMENT
Landmarks of Speech, Language, and Hearing Ability During the Preschool Period

Age (Months)	Receptive Language	Expressive Language	Related Hearing Ability
42	Up to 4200 words; knows words such as *what, where, how, funny, we, surprise, secret;* knows number concepts to 2; knows how to answer some questions accurately, such as: Do you have a dog? Which is the girl? What toys do you have?	Up to 1200 words in mostly complete sentences averaging 4 to 5 words per sentence; uses all 50 phonemes; 7% of sentences are compound or complex; averages 203 words per hour; rate of speech is accelerating; relates experiences and tells about activities in sequential order; uses words such as *what, where, how, see, little, funny, they, we, he, she, several;* can recite a nursery rhyme; asks permission; 95% of speech is intelligible	
48	Up to 5600 words; carries out 3-item commands consistently; knows why people have houses, books, umbrella, key; knows nearly all colors; knows words such as *somebody, anybody, even, almost, now, something, like, bigger, too,* full name, one or two songs, number concepts to 4; understands most preschool stories; can complete opposite analogies such as brother is a boy, sister is a girl, and in daytime it is light and at night it is dark	Up to 1500 words in sentences averaging 5 to 6 words per sentence; averages 400 words per hour; counts up to 3, repeats 4 digits, names 3 objects, repeats 9-word sentences from memory; names the primary colors, some coins; relates fanciful tales; enjoys rhyming nonsense words and using exaggerations; demands reasons why and how; questioning is at a peak, up to 500 questions a day; passes judgment on own activity; can recite a poem from memory or sing a song; uses words such as *even, almost, something, like, but;* typical expressions might include "I'm so tired," "You almost hit me," "Now I'll make something else"	Begins to make fine discriminations among similar speech sounds, such as the difference between *f* and *th* or *f* and *s;* has matured enough to be tested with an audiometer; at this age, formal hearing testing can usually be done; not only has hearing developed to its optimal level, but listening has also become considerably refined
54	Up to 6500 words; knows what materials a house, window, chair, and dress are made of and what people do with eyes and ears; understands differences in texture and composition, such as hard, soft, rough, smooth; begins to name or point to penny, nickel, dime; understands *if, because, why, when*	Up to 1800 words in sentences averaging 5 to 6 words; now averages only 230 words per hour—is satisfied with less verbalization; does little commanding or demanding; likes surprises; approximately 1 in 10 sentences are compound or complex, and only 8% of sentences are incomplete; can define 10 common words and counts up to 20; common expressions are "I don't know," "I said," "tiny," "funny," "because"; asks questions for information and learns to manipulate and control people and situations with language	
60	Up to 9600 words; knows number concepts to 5; knows and names colors; defines words in terms of use, such as a bike is to ride; defines wind, ball, hat, stove; understands qualifiers such as *if, because, when;* knows purpose of horse, fork, and legs; begins to understand *left* and *right*	Up to 2200 words in sentences averaging 6 words; can define ball, hat, stove, policeman, wind, horse, fork; can count five objects and repeat four or five digits; definitions are in terms of use; can single out a word and ask its meaning; makes serious inquiries—"What is this for?" "How does this work?" "Who made those?" "What does it mean?"; language is now essentially complete in structure and form; uses all types of sentences, clauses, and parts of speech; reads by way of pictures, and prints simple words	

Modified from Hockenberry, M. J., & Wilson, D. (Eds). (2015). *Wong's nursing care of infants and children* (10th ed.). St. Louis: Mosby.

During the early childhood years, rhythm develops as an important dimension in speech capacity. Between 3 and 5 years of age, children practice speaking by mimicking adult language patterns. Practice expands neuromotor capacities, and verbal interaction develops vocabulary and sense of grammatical structure. Hesitations, repetitions, and frequent revisions in speech reflect attempts to expand language capacity. Adults may label such preparation as stuttering, but these inaccuracies actually represent normal speech maturation. Stuttering originates during this developmental period, associated with response and reaction from adults and other children to the normal preschool broken speech pattern (Langevin et al., 2009). Reactions of impatience while waiting for the child to express thoughts and negative social interactions decrease the child's opportunities to use language. Insisting children use correct speech before capacity for fluent speech develops may hinder normal speech development. As many as 60% of expressive language delays resolve during the preschool years (Conti-Ramsden & Durkin, 2012). As nurses help parents provide anticipatory guidance for language development, they should maintain vigilance to identify those children who are not outgrowing their language difficulties. These children encounter lifelong obstacles with learning and socialization. Suggestions for nurses to assist parents and to facilitate preschoolers' language development are listed in Box 19-5.

Box 19-5

Nursing Suggestions to Encourage Language Development in Preschoolers

- Read to the child. Encourage the child to be an active listener. Pause during the story to ask questions, such as “What do you think will happen next?” and “Why do you think the boy said that?” and “What would you do now?” Praise the child's storytelling and

creativity with stories.

- Always respond to the child's questions. Occasionally a response must be delayed; for example, when the parent is driving in heavy traffic and the child asks a question that requires a complex answer, the parent might say "That's a very good question; let's talk about that as soon as we get home." The parent should remind the child of the question later and respond if the child still expresses interest.

- Never tease or criticize a child about speaking style. If the child speaks so fast as to be fumbling over words, then the parent might say "I can't listen that fast. Slow down a little for me." This is much more encouraging than is the statement "You talk too fast. No one can understand you."

- Play language-focused games, such as naming the colors of houses or kinds of flowers as parent and child walk to the store.

Memory

Memory plays an important role in language development and learning in general (Archibald et al., 2011). Archibald and colleagues (2011) examined 12 preschool students and demonstrated an association between memory and verbal ability. At the preschool level, children label pictures, group objects, and mimic others as ways to aid memory, performing these tasks with less precision than the older child. Younger children benefit from suggestions about how to group items using characteristics to remember. Preschoolers remember pictures better by saying names of pictures rather than simply hearing the name of a picture when it is first shown. Preschoolers do not spontaneously use rehearsal or other **mnemonic techniques** for remembering, but they do use and benefit from rehearsal when it is suggested. The nurse tests memory by asking the child to repeat an arbitrary sequence of numbers. By approximately age 5 years, children are able to repeat four consecutively named numbers easily.

Testing of Developmental Level

Parents of preschool children determine their child's readiness for school programs. The child's skill level, the child's and the family's psychosocial status, and the characteristics of the school program under consideration contribute to readiness determination. Early identification of developmental and emotional disorders is critical to the well-being of children and is an integral function and an appropriate responsibility of all pediatric health care professionals.

To obtain a more specific measure of developmental age, the nurse uses one of several screening tools designed for use with the preschool child. These validated instruments help to identify children at risk of developmental delay or disorder. Screening instruments are not diagnostic tools. In the primary care setting, screening for developmental age can be performed through the third edition of the **Ages & Stages Questionnaire (ASQ-3),** a 30-item parent-report tool for children aged 4 to 60 months. The questionnaire takes caregivers 10 to 15 minutes to complete and takes approximately 2 to 3 minutes to score. ASQ-3 addresses five developmental areas: communication, gross motor, fine motor, problem-solving, and personal-social skills (Schonhaut et al., 2013). The **Battelle Developmental Inventory** is administered by a professional, trained in administering the test, and is designed to screen children from birth to 95 months old for personal-social, adaptive, motor, communication, and cognitive developmental problems. The Battelle Developmental Inventory is commonly used by early intervention programs and also in the primary care setting. The **Parents' Evaluation of Developmental Status** is another parent-completed questionnaire used commonly in the primary medical home setting and preschool setting. It is validated on children aged 0 to 8 years, takes 2 to 10 minutes to complete, and screens children for developmental and behavioral problems.

When a screening tool result is positive/concerning, the nurse should take additional steps to meet the needs of the parent and child. An early return visit should be made to provide additional developmental surveillance as well as anticipatory guidance for the

family. Most importantly, the child should be referred for developmental and/or medical evaluations. Early developmental intervention/early childhood services should also be initiated if necessary.

Children who are ready for school demonstrate competencies in areas other than measurable skill performance. Complex home environments with stable caring adults or safe, predictable physical environments with regular, stimulating activities, peers, and materials contribute to readiness. Social norms define expectations; therefore home values that align with school values are more likely to result in children characterized as ready for school. Conversely, when school expectations differ from those at home, children are less likely to be considered ready for school (Conti-Ramsden & Durkin, 2012).

Autism Spectrum Disorders

Autism statistics from the US Centers for Disease Control and Prevention (CDC; http://www.cdc.gov/) identify approximately 1 in 68 American children as being on the autism spectrum. Autism is 4.5 times more common among boys than girls. Autism has been diagnosed in an estimated 1 in 42 boys and 1 in 189 girls in the United States. Autism spectrum disorder (ASD) is the umbrella diagnosis for all subtypes (autistic disorder, childhood disintegrative disorder, pervasive developmental disorder—not otherwise specified, and Asperger syndrome). For the US population, the prevalence rate for this continuum of conditions increased from 6.7 per 1000 children in 2000 to 9.0 per 1000 children in 2006, and then to 14.6 per 1000 children in 2012 (CDC, 2016a). This corresponds to about 1 in 150 children in 2000, 1 in 110 children in 2006, and 1 in 68 children in 2012 (CDC, 2016a).

These conditions are considered genetically determined disorders and are only rarely associated with nongenetic risk factors, such as maternal valproic acid use during pregnancy, congenital rubella, and cerebral palsy (Freitag et al., 2010). Although the genetic foundation is well recognized, no single gene or gene family is linked to the disorders (LeBlanc & Fagiolini, 2011; Mefford et al., 2012).

Chromosome microarray analysis is a promising area for assessment of ASD and currently provides diagnosis 15% to 20% of the time (Mefford et al., 2012).

Multiple studies have linked ASDs with atypical birth weight (high or low), low Apgar scores, hemolytic disease, hyperbilirubinemia (jaundice), respiratory distress, advanced parental age, length of gestation, and environmental factors (viruses), all of which may be subtle and complicated by the genetic influence (May-Benson et al., 2009). In their study of 467 children with ASD, May-Benson and colleagues (2009) provided support for the idea that there is no unique combination of characteristics, but rather a composite of risk factors that provide suspicion for the disorders.

More recently, there has been a question on whether an association between assisted reproductive technology (ART) conception and autism exists. Fountain and colleagues (2015) found in a population-based sample in California that the incidence of autism was twice as high for ART births as for non-ART births. However, they also explain that the association between ART and autism can be primarily explained by adverse prenatal and perinatal outcomes and multiple births. Research is also being performed to look at potential differences in ART procedures and parental infertility diagnoses as they might factor into the incidence of autism in ART-conceived infants. For example, there is a higher incidence of autism during the first 5 years of life when intracytoplasmic sperm injection was used compared with in vitro fertilization and a lower incidence when parents had unexplained infertility (among singletons) or tubal factor infertility (among multiples) compared with other types of infertility (Kissin et al., 2015).

Careful observation is vital during this time of language and communication development to assess children for ASDs because most cases of ASD are diagnosed in children (LeBlanc & Fagiolini, 2011). Most children have symptoms in the first year of life (Shumway et al., 2011); however, a formal diagnosis of autism is typically not made until a child is 2 years old. This assessment includes the family history, clinical history, and physical assessment with a focused

neurological examination. Various screening tools exist for the nurse to use to identify children at risk of autism. The Modified Checklist for Autism in Toddlers is a widely used, 23-item, parent-completed screening tool for children aged 16 to 48 months (Chlebowski et al., 2013). For older children, the Childhood Asperger Syndrome Test and the Social Communication Questionnaire are well-developed and validated screening tools.

Manifestations differ considerably (Freitag et al., 2010; May-Benson et al., 2009). Assessment of cognitive and behavioral symptoms is the cornerstone of diagnosis, and early detection may help families address advancing behavioral aberrations sooner (LeBlanc & Fagiolini, 2011). The families of these children manage multiple behavioral and physical challenges early in the child's life; therefore health providers need to remain apprised of current trends in pediatric development connected to the disorders (May-Benson et al., 2009). Providers should consider the prenatal events mentioned earlier in this section along with childhood stressors (e.g., chronic ear infections, sleeping/eating problems, absent/brief crawling phase, language delays, atypical responses to sensory stimulation, lack of separation anxiety, and failure to attain motor skill developmental milestones) as warning signs that warrant further assessment (LeBlanc & Fagiolini, 2011; May-Benson et al., 2009).

In 2016 a population-based ASD surveillance study was published that looked at the characteristics and prevalence of ASD in 4-year-old children (Christensen et al., 2016). The study authors concluded that when compared with diagnosis in 8-year-old children, ASDs were diagnosed in the 4-year-olds approximately 5 months earlier (27 months compared with 32 months respectively) demonstrating improved methods of early identification. They also found that 4-year-old children with ASD were more likely to have intellectual disability than 8-year-old children in the same communities. Lastly, they concluded that among 4-year-old children, girls and white children were more likely to receive their first comprehensive, developmental evaluation by age 3 years compared with boys and black children, demonstrating that although there have been improvements in early

diagnosis, at-risk populations still exist for later diagnosis/identification.

It is critical that autism and developmental delay be detected early in an effort to minimize delay and reduce educational costs. Neural circuits, which create the foundation for learning, behavior, and health, have increased plasticity within the first 3 years and become increasingly difficult to change over time. Diagnosis in the preschool child or earlier is imperative. The brain in strengthened by positive early experiences, stable relationships, appropriate nutrition, and supportive environments. High-quality early intervention can change the child's developmental trajectory and improve outcomes for families, children, and communities (Center on the Developing Child at Harvard University, 2010).

Self-Perception–Self-Concept Pattern

During the preschool years, basic self-concept emerges from the child's personal struggle for autonomy. As children develop beyond the toddler years, they refine their sense of self through both task-oriented and socially oriented experiences. By reinforcing skills and successfully accomplishing tasks, preschoolers build self-esteem, enhancing overall health. Social acceptance helps children feel successful in their role as a child, sibling, and friend. Preschoolers investigate roles through rich imagination. Pretending to be the parent or baby allows preschoolers to imagine experiences and feelings of others (i.e., empathy) and safely experiment with new ideas (Price & Gwinn, 2008).

Preschool children learn about their roles in their child care environments and learn that being dependable within their world is important. When children perceive their value in improving the world in which they live, they experience good feelings about themselves and, ultimately, demonstrate improved mental and physical health. Many simple ways to improve the environment are available, and when children learn ways to contribute to environmental health, they often reinforce these behaviors in their parents (Box 19-6: Quality and Safety Scenario).

Box 19-6

Quality and Safety Scenario

Health Promotion With Preschoolers: Environmental Accountability

Rationale for Teaching Preschoolers About Environmental Protection

- Environmental education at an early age will produce environmental practitioners of the future.
- Preschoolers can learn basic concepts of environmental accountability and gain a sense of empowerment when they perceive that they make a difference to the future world.
- Health care providers, in consultation with child care providers, can promote environmental education that is based on their knowledge of child growth and development and concerns about overall health.

Basic Ways for Preschoolers to Help the Environment and Promote Overall Societal Health

- Use water wisely.
- Use electricity only when necessary.
- Recycle.
- Avoid using balloons.
- Plant trees, protect plants, and grow a garden.
- Create a compost pile.

- Care for birds.
- Clean up the neighborhood.
- Decrease the amount of trash; say “no” to Styrofoam and plastic garbage bags, and use paper cups and reusable cloth bags for groceries.
- Recycle old toys by giving them to others.
- Buy and use only Earth-friendly school supplies.
- Walk rather than ride in the car.
- Use live Christmas trees and replant them.

Erikson's Theory

Preschoolers develop a sense of **initiative** through their vigorous motor activity and active imagination (Figure 19-2). Erikson views this growth as the most central developmental task in the emerging self-concept of the preschool years. By praising preschoolers' efforts and providing opportunities for new experiences, parents promote development of initiative. Rather than requiring a particular behavior, parents should provide avenues for experimentation. Preschoolers then feel mastery, thus encouraging repetition. With mastery, preschoolers become more confident about trying new actions.

FIGURE 19-2 Two preschoolers using their imagination in being movie stars.

Roles-Relationships Pattern

Family members continue to play a vital role in the preschooler's life, but peers become increasingly significant as development progresses. Preschoolers receive ideas and information from peers. They may subsequently question rules or expectations at home, comparing them with their friends' situations. Discussion about family values and behaviors that are acceptable in one place but not another helps them understand differences.

Preschoolers understand sex expectations regarding jobs, activities, and competencies of people in their lives. Ideas about sex differences in work roles or activities are based on models in the home, at child

care or preschool centers, and on television. Parents and caregivers should be aware of the powerful influence that the environment has on role perceptions (Bower et al., 2008; Brown et al., 2009; Kochanska et al., 2010). When inaccurate portrayals of male and female roles are depicted, parents and caregivers should discuss more accurate ones with children. Preschoolers experiment through play, including adopting family roles. These roles differ depending on the family structure and function. For example, the role-play for a child of gay or lesbian parents may differ from that of a child of heterosexual parents. As the mother or father in a play situation, the preschooler sets limits, punishes, praises, and makes outlandish demands on the invented child. Play represents an important strategy for preschoolers to use for stress reduction and experimentation with new roles. By playing different roles, children safely experience the effects of their behavior and understand others' roles more clearly. Parents also better understand the effects of their own actions when they observe the behaviors of their child. Nurses help parents use their observations to improve interactions with their child.

Compared with toddlers, preschoolers relate to older children in the family on a more equal basis. Although their cognitive, motor, and language skills are less refined, preschoolers participate in some activities with their older siblings. Younger children may admire and imitate an older sibling. This behavior flatters the older child initially, but with continued persistence may develop into a source of frustration for the sibling. The older sibling, in a more powerful position, may resort to violence (Phillips et al., 2009).

Social interaction during the preschool period prepares the child for school. Through experience within the family, with peers, and with other adults, the child acquires readiness to interact in group situations, follow directions, take turns, recognize others' rights, channel energy toward an assigned activity, and demonstrate increasing independence. School readiness can be assessed by use of several relevant tests, as discussed in this chapter. The nurse who sees the child repeatedly in an office, clinic, or group care or preschool setting assesses progress as the child develops social competencies.

Comparing the preschooler's current, more mature behavior with previous behavior provides insight into that child's readiness for school. This method of evaluation, however, prevents comparison with other children of the same age. For example, school personnel may view a child who reflects a quiet temperament and is introverted or subdued as overly attached to the mother in comparison with other children the same age. However, if the child's earlier social behavior is known, the behavior may be interpreted as a progression toward independence.

Evidence of social competency can be obtained by discussion and evaluation of the child's family drawings. Children can be given the opportunity to draw pictures while they are waiting for outpatient visits, and the drawings can be used to begin the assessment process. The nurse observes the drawing and responds to any comments or questions volunteered by the child. When asked for advice or assistance, the nurse encourages the child to proceed with drawing. Positive encouragement for the child's efforts may be used, particularly with reluctant children. After the drawing is finished, the nurse discusses the sketch with the child to identify the people and describe individual characteristics. The nurse writes the names of each family member on the picture and documents the perceptions the child describes. Open-ended questions such as “What do you like best about your brother?” or “When do you get angry with your sister?” can be posed to encourage the child to describe the family interaction patterns. When an adult family member is present, the nurse explains the purpose of the drawing and interview and requests that the adult withhold comments or questions until the activity is completed. Any areas of concern or questions should be discussed, assuring the parent that confidentiality will be maintained. The child's perceptions can be verified with the adult at the conclusion of the interview, or further information can be sought to clarify them.

The **Vineland Social Maturity Scale** provides an objective, standardized estimate of social functioning and social maturity (Scattone et al., 2011). This tool profiles the child's self-help skills, self-direction, locomotion, communication, and social relations. The

scoring system seems to be culturally and socioeconomically neutral. The investigator collects data by observing the child's behavior and interviewing the mother or primary caregiver. Designed to measure progression toward independence, this instrument uses direct observation of the child's behavior whenever possible, with the interview data being used only if needed to complete the assessment (Scattone et al., 2011).

These kinds of tools elicit cues indicative of family stress and strain. **Parental divorce** commonly creates disruption in family relationships. Discussion of the results of the assessment offers the opportunity to discuss family situations that otherwise might have remained unmentioned. Children's responses to changes in family circumstances depend on their developmental stages and their relationships before the change. Divorce represents a final decision, usually culminating from a period of conflict, stress, and changing relationships. Although preschoolers definitely sense stress in the home, they cannot articulate their feelings or determine their origin. Children react to changes in various ways, including regression, confusion, or irritability. Asking the same questions repeatedly—such as "Is Daddy coming home for supper tonight?" or "Why doesn't Daddy stay here anymore?"—can be a child's way of expressing difficulty in coping with or comprehending the situation.

Parents in the midst of marital problems or divorce frequently lack the psychological energy or patience to deal with questions and altered behavior. Nonetheless, their children desperately need closeness, patience, and consistent responses from their parents. Nurses act as advocates for children by helping parents explore ways to address regression and irritability. As parents develop skills to explain situations, they realize children are deeply affected during times of family disruption, regardless of their behavior (Kaakinen et al., 2010). Parents need to connect emotionally with their children to demonstrate that love will continue for the child despite dissolution of the marriage. Books appropriate to the preschooler's cognitive and emotional level can help parents address children's feelings and needs during divorce.

Child Abuse

The social processes within families and communities that create child abuse are multifaceted and complex. Research focuses on the complexity of the abuse cycle and the challenges involved in resolution. In some communities, hitting children as a form of discipline remains socially acceptable. Parents and caregivers who experience workplace stress, financial worries, and other frustrations may project their anger and abuse toward their children physically, emotionally, or sexually. Effective primary and secondary prevention interventions involve promoting awareness of violence as a social problem, opposing violence to women, and offering community or school programs to teach nonviolent conflict resolution skills to people of all ages. Prevention of child neglect and abuse is the focus of many health-promotion programs. Recognition of signs of child abuse is important, and health care are mandated to report suspected abuse (Moreno, 2014). Although it is important for families to begin to teach children about how to respond to strangers, child abuse in general and sexual abuse in particular occur more often within a family than with a stranger as the perpetrator. Most children suffer the abuse from someone who is familiar to them. The American Psychological Association provides helpful information about abuse for families at http://www.apa.org/pi/families/resources/child-sexual-abuse.aspx.

Sexuality-Reproductive Pattern

Preschoolers recognize there are two sexes and identify with their own sex. Appropriate and positive representations of both sexes on television and in role models, such as working mothers, allow preschoolers to interpret gender roles broadly and define their own roles more realistically (Hockenberry & Wilson, 2015). Body image, a part of gender identity, also includes perception of sex organs. Preschoolers develop curiosity at this age, including inquisitiveness about bodies and sexual functions of others. Questions should be answered simply and factually. Teasing preschoolers about this interest or implying that sexual information is unacceptable or

naughty promotes negativity. Positive feelings about all aspects of the self (including gender role) create positive self-esteem. Many children's books address self-esteem in young children and provide interesting and informative approaches to nurturing overall health promotion in this age group.

Coping–Stress Tolerance Pattern

Play Approaches

Assessing self-concept in preschool children who struggle to articulate their feelings presents a challenge for the nurse. Play can elicit behaviors that indicate sense of self and self-esteem, future success or failure, sense of acceptance, and competence. **Doll or puppet play** provides valuable insight into a child's sense of self. Dolls or puppets, including those representing a young child of the same sex, race, and cultural background as the preschooler, should be available (Hockenberry & Wilson, 2015). If the child spontaneously begins to engage the dolls or puppets in imaginary activity, no further guidance should be given. With a reluctant child, the nurse begins to pretend, using examples for the child, such as going to the store, moving the dolls through the related activities, and then involving the child. Frequently preschoolers continue the scenario to tell their personal stories.

A related technique is **mutual storytelling.** The nurse begins a story for the child to finish. The nurse might begin with a standard line, such as "Once upon a time there lived a [girl, boy, cow, monkey, etc.] who … ." The nurse then pauses for the child to continue. If the child hesitates, the nurse resumes the story for another sentence or two and asks what the figure in the story is doing. As the child supplies details, the nurse offers encouragement to continue, asking questions such as "And then what happened?" or "How did the child feel?"

The child's inner nature can be explored along several dimensions. The emotional theme of the story is noted and should be congruent with the child's tone and expression. For example, a child who centers on a theme of aggression and destruction but describes the character's

anger in a monotone is demonstrating incongruence between content and expression. The child's emotionless response suggests difficulty with expressing feelings. At the conclusion of the story, possible meanings can be revealed by the nurse asking whether the child feels similar to any of the characters or would like to be any of the characters.

Although these dimensions may be explored for meaning, interpretation of a child's behavior in these play situations remains highly speculative. Determining possible themes or estimating the child's self-esteem requires several encounters. Additionally, the nurse's personality and approach influence the child's spontaneity and ability to tell a story. Observed behavior and responses without associated interpretation should be recorded for future reference. Interpretations of the behavior and responses are avoided until validated by a specialist.

Coping Mechanisms

Preschoolers use coping mechanisms similar to those of the toddler (separation anxiety, regression, denial, repression, and projection). Protest behavior in the form of temper tantrums normally disappears as a stress response in the older preschooler. Temper tantrums that persist through the fifth year indicate a lack of matured coping responses. The child uses tantrums and continues to gain the desired result.

Preschoolers lack the cognitive awareness, social abilities, and motives for communication of adults and older children. They display temperaments and tantrums that appear oppositional to older individuals. Through positive interactions with parents and caregivers, preschoolers frequently learn how to organize their bodies, abilities, and environment to move successfully to the next stage of development (Brown et al., 2009; Luby et al., 2009). A positive relationship between the child's temperament and the demands of the environment (also known as goodness of fit) can be attained by social interaction, which, in turn, prevents the development of problem behaviors later (Box 19-7: The Challenge of Temperament and

Preschoolers).

Box 19-7

The Challenge of Temperament and Preschoolers

Temperament describes the way in which an individual behaves or responds to new situations and to life occurrences and has consistently been associated with psychopathology and family function since the early work of Terry Brazelton with maternal attachment in 1978 (Healey et al., 2011; Joosen et al., 2012). Most children can be defined as *easy, difficult,* or *hard to warm up to* on the basis of how they react to their surroundings and to people. Temperament and parental stress are linked; however, multiple other factors influence interactions between the parent and the child, including the child's own temperament (Healey et al., 2011; Prior et al., 2011). For many adults, the challenge in parenting is to learn how to work with a child's temperament, which can differ from the parents' or other children's temperaments, in efforts to attain family happiness. Coping skills and stress management for families, particularly those with children defined as difficult, may improve family function (Healey et al., 2011).

From Healey, D. M., Flory, J. D., Miller, C. J., & Halperin, J. M. (2011). Maternal positive parenting style is associated with better functioning in hyperactive/inattentive preschool children. *Infant & Child Development*, *20*(2), 148–161; Joosen, K. J., Mesman, J., Bakermans-Kranenburg, M. J., & van Lizendoorn, M. H. (2012). Maternal sensitivity to infants in various settings predicts harsh discipline in toddlerhood. *Attachment & Human Development*, *14*(2), 101–117; Prior, M., Bavin, E., Cini, E., Eadie, P., & Reilly, S. (2011). Relationships between language impairment, temperament, behavioural adjustment and maternal factors in a community sample of preschool children. *International Journal of Language & Communication Disorders*, *46*(4), 489–494.

Preschoolers possess a considerable range of experiences and memories; therefore they respond more maturely to stress than do toddlers. Positive coping resources are determined by some of the following variables:

- Availability of emotional comfort and the child's inner resilience
- Ability to work on task
- Availability of play materials and toys
- Opportunity to engage in activities (Kalpidou et al., 2004)

Preschoolers use many of the coping mechanisms developed during their toddler years, but they generally show greater ability to verbalize frustration, have fewer temper tantrums, and display more patience in experimentation to resolve difficulty than the typical toddler. Preschoolers refine their problem-solving skills. Through fantasy play, they investigate solutions or responses to stressful events and find inner control for challenging situations.

Occasionally projection and fantasy lead parents to consider their child dishonest. When faced with the question "Did you break this dish?" the preschooler might respond, "No, Teddy did it." The child might even relate a detailed story of the toy bear mishap. Preschoolers tend to project blame. Active fantasies help tell the story. Parents should not accuse the preschooler of lying, but rather the adult should help the child decide whether the story is pretend or real. The concepts of pretend and real help encourage children to discuss nightmares, television shows, stories, and their own active imaginations (Garrison et al., 2011).

Compared with toddlers, preschoolers better perceive their ability to control and manage situations. Strict adherence to rituals or game rules controls situations. As discussed, preschoolers have longer and more rigid bedtime rituals than those of toddlers. Preschoolers also dislike losing games and may structure the rules to ensure they win. Older children and adults may be able to accept these structures, but these controlling behaviors frustrate other preschoolers because they also need to win. Gentle, consistent direction by parents and caregivers about how to play games fairly and how to move toward positive group outcomes helps preschoolers develop a sense of morality, which is important for later life success and happiness. See the case study and care plan at the end of this chapter for an example of ineffective coping in a preschool child.

Values-Beliefs Pattern

Preschoolers, like toddlers, lack fully developed consciences; however, at age 4 to 5 years these children do demonstrate some internal controls on their actions. Immaturity limits the consistency and effectiveness of these internal controls. With the child's concrete perspective, the internal controls may be rigid; therefore a preschooler may feel overwhelming guilt when behavior and internal controls conflict. Cognitive developmental level determines, for the most part, preschoolers' maturity and their feelings about their behavioral fluctuations. Cognitive development continues with dramatic transformation during these years, explaining the differences not only among children but also for different times in the same child. Modeling and **induction explanation,** moving from specific to general, influence moral behaviors appreciably. Modeling stems from many sources, not all of which leave positive impressions. Parents affect the availability of models by screening television shows, carefully selecting child care situations, and monitoring play sessions. Responsible parents verify the suitability of the models. More detailed inductive explanations, based on the child's cognitive level, are generally comprehended by the preschool population.

Preschoolers control their behavior to retain parental love and approval. From their perspective, parental disapproval represents a decrease in the child's importance from the parent's viewpoint. The child therefore suffers a decline in self-esteem, which motivates a change in behavior. Guilt results from perceived reduction of self-esteem, a critical step in the development of conscience. Moral actions are demonstrated in simple activities, such as taking turns and sharing. These actions stem from the assumption that other people have rights and desires that are as important as the rights and desires of preschoolers.

Preschoolers frequently express their values by stating who or what they like or what they want to be when they become adults. These values change frequently, even within a few minutes. Preschoolers occasionally use statements of value as punishment for playmates or family members and display insensitivity to the effect of their remarks

on others. Preschoolers ask endless questions. When they ask these questions about moral actions or feelings, they may simply be asking "How does this work?" and not questioning the underlying parental value. The same intent exists when the child asks about the spiritual values that the parent may be teaching. Parents may enroll their child in Sunday school or other faith-oriented classes or activities. The preschool child generally enjoys the social aspects of these activities and receives some important modeling of values from the involved adults and from working with peers as they struggle to develop morality (Kochanska et al., 2010).

Life beginnings and death concepts fascinate preschoolers. Because of their limited emotional experiences with death, some ask about dead insects and the process of death with great interest, occasionally with insensitivity. Others become upset with the idea of dying, assuming that when someone becomes angry and wishes them dead, they will cease to exist. Many children worry about who will care for them if their caregivers die, whether pain comes with death, what causes death, and what happens after someone dies. Children who actually lose a loved one to death can experience sleep disturbances and other behavioral changes as part of the grieving process. Parents, on the basis of their own religious and cultural values, should respond to children in a supportive and open manner to provide an accurate interpretation of death. In some cases, counseling may be needed if the parents are unable to cope with their duties or if the child has significant behavioral problems as a result of the family disruption. Assessment using the preschoolers' drawings in such situations provides an accepted method to explore their perceptions about family relationships, death, and the afterlife (Selwyn et al., 2009).

Environmental Processes

Physical Agents

For many children, physiological, psychosocial, and environmental factors create health problems that interfere with physical, social, and educational activities of normal development (Hockenberry & Wilson, 2015). Major disruptions limit fulfillment of the child's potential in adulthood. The environmental processes that affect toddlers also affect preschoolers. Occurrence rates and outcomes of health problems differ in this age group, likely because of developmental differences (US Department of Health and Human Services, 2011). Preschoolers have more refined problem-solving skills, are more coordinated, and have more experience with a variety of situations than do toddlers. Although preschoolers recognize and avoid some environmental hazards, they remain impulsive and immature. Population-based programs ensure that screening occurs at the most developmentally appropriate time (Box 19-8: Research for Evidence-Based Practice).

Box 19-8

Research for Evidence-Based Practice

Effectiveness of Parents' Language Interventions for Preschool Children

Roberts and Kaiser (2011) conducted a systematic meta-analysis of 18 studies with participants aged 18 to 60 months that met the following criteria: used a comparison group, used a parental intervention, and included a child communication component with at least one language outcome measure. Almost half of the studies evaluated used the Hanen Program for parents and focused stimulation. Effect sizes were determined for each study, as well as seven language outcome variables. Intellectual disabilities and parent report versus direct observation measures were also compared. This meta-analysis

indicated that parent-implemented language interventions have significant positive influence on both receptive and expressive language skills in preschool children regardless of whether they have intellectual impairment. The findings from this analysis provide evidence to support the use of parent-implemented interventions for preschool children with language impairments.

From Roberts, M. Y., & Kaiser, A. P. (2011). The effectiveness of parent-implemented language interventions. A meta-analysis. *American Journal of Speech-Language Pathology, 20*(3), 180–199.

Because many preschoolers attend child care programs, many have been trained to use 911 and can access help in emergencies when this phone code exists. At this age a child needs to know his or her name, address, and how to say "no" to strangers.

Injuries

Accidents and injuries are often predictable and preventable (CDC, 2007; Ingram et al., 2011). As preschoolers become more independent, causes of injury change; they may chase a ball into a busy street or suffer from sports-related injuries. Preschoolers continue to need supervision to prevent injury related to their developmental age. Nurses guide families to provide a safe environment for preschoolers with opportunities to explore without negative consequences (Box 19-9).

Box 19-9

Injury Prevention for Preschoolers

A safe and developmental-stimulating environment allows children of all ages to explore without negative consequences. When teaching parents how to modify their homes for preschoolers, the nurse should consider the following requirements for child safety.

Safe Sleep Environment

Provide beds with guardrails (as needed), soft corners, and

appropriate bedding to prevent suffocation.

Well-Ventilated but Optimal Temperature Environment for Play

Provide safe play areas by using electrical outlet covers, handrails in stairwells, toy boxes with lids that lock securely, nonslip floor materials, well-anchored furniture, and appropriate soft ground coverings and padding for outdoor play equipment.

Burn Prevention

Use only cool mist humidifier for management of upper respiratory tract infections; dress child only in flame-retardant clothing, particularly at bedtime.

Appropriate Installation and Use of Emergency Home Equipment

Discuss the importance of properly operating smoke detectors and fire extinguishers, and practice a plan for escape from the home in case of emergency.

Connection to Emergency Services

Post 911 on all phones; teach the child how to use 911 and how to report the child's name and address over the phone; parents should be trained in cardiopulmonary resuscitation and the use of abdominal thrusts.

Prevention of Aspiration

Monitor use of balloons and eating habits of preschoolers.

Safe Daily Home Environment

Close doors of the dishwasher, oven, washer, and dryer; mark all glass doors with decals to delineate doors; use gates at the top and bottom of stairs for the younger child; set water heater temperature at a maximum of 120°F to avoid burns; store all poisonous substances

out of the reach of children; discourage running in the house; avoid using throw rugs on bare floors.

Prevention, Recognition, and Management of Poison Ingestion or Exposure

Know how to use syrup of ipecac, and have the nearest poison control center phone number within easy access; learn how to evaluate burns or blisters around the mouth, odor of poisons, empty containers around the child, stomach distress, or changes in normal activity level that might indicate poison ingestion.

Water Safety

Monitor bathtub and pool activity; teach preschooler swimming skills (usually by age 4 years); ensure that all pools are fenced.

Bicycle Safety

Ensure that the child is riding a developmentally appropriate bicycle with a federally approved safety helmet and is schooled in the rules of riding in the street and interacting with strangers.

Lead Concerns

Avoid exposure to items with a high lead content in the home (paint, wrapping paper, earthenware, colored newspaper); ensure that children are monitored when lead exposure is a concern.

Environmental Contaminants Hazardous to the Child's Health

Avoid exposure to tobacco smoke, nitrous oxide from wood-burning stoves, asbestos, pesticides, radiation, and factory-produced irritants.

From Hockenberry, M. J., & Wilson, D. (Eds). (2015). *Wong's nursing care of infants and children* (10th ed.) St. Louis: Mosby.

Of all injuries, two-thirds occur in children and adolescents. The rate of death from injuries is decreasing in the United States. On the

other hand, death rates continue to be higher than in countries with long-term comprehensive preventive approaches that focus on widespread community change (e.g., Great Britain and Scandinavian countries) (Orton et al., 2012). Although preschoolers have fewer accidents than toddlers, accidental injury continues to be a predominant cause of morbidity in this age group (Orton et al., 2012). Preschoolers are most likely to sustain injuries related to falls, poisonings, and thermal injuries than any other accidental injuries; however, as the child's age increases toward school age, these injuries begin to decline in number (CDC, 2017; Ingram et al., 2011; Orton et al., 2012).

Motor vehicle accidents consistently remain the top-ranked reason for death attributable to injury in the preschool age group (CDC, 2017). Consequently, the *Healthy People* initiative has promoted the use of car seat restraint systems (*Healthy People 2020:* IVP-16.3). An analysis of data from the National Survey of the Use of Booster Seats revealed that unfortunately few children younger than 13 years use the recommended child passenger restraints (Macy & Freed, 2012). The overall critical misuse for child restraints is approximately 73% (Decina & Lococo, 2005). According to the Fatality Analysis Reporting System (a database maintained by the National Highway Transportation Safety Administration), from 2001 to 2010 there were 7625 motor vehicle crash fatalities of children aged 0 to 9 years, of which only half were wearing any child restraint and 20% were sitting in the front seat (Lee et al., 2015). To promote correct car seat use, Weaver and colleagues (2013) recommend conducting meaningful formative research, developing and evaluating injury prevention message strategies, evaluating existing programs and recommendations, conducting transdisciplinary work, and supporting partnerships between manufacturers, retailers, and injury prevention specialists.

As children outgrow a rear-facing car seat at approximately age 2 years, they should move to a forward-facing car seat with a five-point harness. Children should remain in a forward-facing car seat with a harness for as long as possible, up to the highest weight and height

allowed by the car seat manufacturer. School-aged children should transition to a booster seat when the weight and/or height are above the forward-facing limit. Children may transition out of a belt-positioning booster seat typically when they have reached 4 feet 9 inches in height and are between 8 and 12 years of age. Federal investigations concluded that children younger than 13 years should ride in the back seat of a motor vehicle, particularly because of potential injury or death from a passenger seat air bag that could inflate in a severe car accident. In 2013 changes were made by car manufacturers regarding the use of LATCH (*L*ower *A*nchors and *T*ethers for *Ch*ildren) for older children using child restraints. This is important in the preschooler because per the new guidelines, in general, if the combined weight of the car seat and child is more than 65 pounds, LATCH should not be used. Instead of LATCH, the seat belt should be used. Each car seat and car manufacturer has slightly differing regulations, so parents are encouraged to have a certified car seat technician install their child's seat to ensure proper and safe installation. It is important to note that each state has differing laws regarding child safety restraints. However, these laws are often minimum requirements, not updated often, and not always reflective of best practice.

Nurses actively participate in health-promotion programs in communities and emergency departments that help families use car restraints correctly. Unfortunately, in one study, despite comprehensive nursing education and training programs during the postpartum period, car safety seat misuse was frequent (Rogers et al., 2013). When families have to consider financial constraints to comply with the requirements to restrain their children, nurses are often the first-line of information. Nurses provide information about resources available locally through agencies such as hospitals, physicians' offices, insurance companies, United Way, local Safe Kids coalitions (2015), the fire department, and other community organizations.

Household furniture and fixtures also remain a hazard for preschoolers, as do structural features such as stairs and windows. A meta-analysis found that home safety interventions were effective in

significantly increasing the proportion of families with fitted stair gates (Kendrick et al., 2013). Nursery and toy injuries decrease during the preschool years. Sports and recreational injuries increase markedly. This elevated incidence likely reflects a change in many preschoolers being involved in group sports, riding bicycles, and using playground equipment (CDC, 2017). Preschoolers need a broad range of play areas and experiences. Conscientious parents supply age-appropriate limits and supervision (Ingram et al., 2011; Price & Gwinn, 2008). Preschoolers lack the skill or judgment to ride bicycles in the street. They need instruction about safe use of playground equipment. Adult supervision of most preschooler activities, group sports in particular, is required to prevent injury.

Preschoolers begin to safely handle basic tools, kitchen equipment, and cleaning supplies. Children at this age take pride in participating in household projects with a supervising parent. They spend much of their time in the home and in the preschool or child care center. The facilities pose the same potentially harmful environmental conditions as the home, as well as some additional threats to safety (CDC, 2007).

In response to concern about firearm safety in homes with small children, most states have passed child access prevention (CAP) legislation to encourage safe storage of firearms. For young children, CAP results in a decline in the rate of deaths attributable to firearms. The risk of death increases in the mere presence of the firearm. Preschool children are physically capable of pulling a trigger before they are able to cognitively depict the cause and effect of their actions. Even if there is gun safety training, most curious children will handle firearms given the opportunity, which may give families a false sense of security (Children's Defense Fund, 2012).

To appreciate the magnitude of the problem, in 2008 the number of preschoolers killed by firearms (88) was twice that of the number of law enforcement officers killed by firearms (41) (Children's Defense Fund, 2012). A more recent estimate reports 110 unintentional firearm deaths in the United Sates of children aged 0 to 14 years annually from 2005 to 2012 (Hemenway & Solnick, 2015). Most deaths from firearms are preventable when adults take responsibility for

minimizing access to and storage of firearms (Faulkenberry & Schaechter, 2015). A recent review of the effectiveness of interventions to promote safe firearm storage found that safe storage device provision, with or without counseling, significantly improved firearm storage practices (Rowhani-Rahbar et al., 2016).

Burns

Scalds and direct flame burns are major hazards for preschoolers. For many young children, thermal injury results in an emergency department visit or hospital admission (Ingram et al., 2011). Thermal injury (unintentional fire/burn) ranks among the top ten causes of death from injuries in US children from birth to 14 years of age (CDC, 2017). The number of deaths of preschool children in house fires is nearly double that of children of other ages. Children of this age experiment with matches and fire, and they may be unable to escape from a fire once it starts. The measures discussed in Chapter 18 to reduce scald burns in the home apply to this age group as well. Preschoolers should be taught about the dangers of matches, open flames, and hot objects. Parents and caregivers should model appropriate use of active and potentially dangerous burning devices. In a study of five emergency departments, the majority (58%) of thermal injuries were scalds from beverages (49.6%), domestic water (37.6%), and food (12.7%), most frequently caused by pull-down (48%) and spill (32%) mechanisms (Kemp et al., 2014). A meta-analysis found that home safety interventions were effective in significantly increasing the proportion of families with safe hot tap water temperatures, functional smoke alarms, and a fire escape plan (Kendrick et al., 2013).

Drowning

Children older than 3 years are at lower risk of drowning in the bathtub, but at greater risk of drowning in a swimming pool, than the toddler. Drowning ranks among the top six causes of death from injuries in US children up to 14 years of age (CDC, 2017). Preschool

children aged 1 to 4 years are at highest risk of drowning, with two near-drowning episodes for every fatality. Most children are close to safety when drowning occurs. With this in mind, it is important to supervise young children when they are near a body of water, to install fencing to isolate a residential pool from the house, for young children to use personal floatation devices while bathing or playing near a natural body of water, and to teach children how to swim and that swimming alone is unsafe. Preschoolers should receive instruction in water safety and swimming, and should always be supervised by a trained adult or older person. The American Academy of Pediatrics suggests that all children aged 4 years or older should receive swimming lessons (Engel, 2015). Because a good outcome depends on early resuscitation, it is reasonable to encourage parents and pool owners to learn cardiopulmonary resuscitation.

Preschoolers have the cognitive ability to learn water survival. They should always wear a personal flotation device or PFD (i.e., life jacket) when they are on boats, even when they know how to swim, and they must be supervised when near water, even shallow water. The American Academy of Pediatrics recommends the following strategies to prevent drownings: adult supervisor, pool fencing, pool alarms, lifeguards, cardiopulmonary resuscitation training, swimming instructions and water-survival training, and PFDs (Weiss, 2010). Safety campaigns provide one effective measure to prevent unnecessary injury and death (Children's Defense Fund, 2012; Ingram et al., 2011; Orton et al., 2012; US Department of Health and Human Services, 2014). Unfortunately, data from the National Inpatient Sample and Nationwide Emergency Department Sample indicate that despite safety campaigns, the estimated national incidence of nonfatal drowning from 2006 to 2011 was constant at approximately 10 nonfatal drownings annually per 100,000 population (Felton et al., 2015).

Mechanical Forces

Bicycle accidents become a greater source of injury during the preschool years. Many bicycle accidents involve automobiles, and

most of these accidents result from the child's errors. Parents should set reasonable and age-appropriate limits on bicycle use. An epidemiological study of nonfatal bicycle injuries seen by emergency departments (Chen et al., 2013) reported that 5.6% of patients were aged 0 to 4 years (110 injuries per 10,000) and 20.5% were aged 5 to 9 years (389 injuries per 10,000). In children aged 0 to 4 years and children aged 5 to 9 years, 17% and 39% of injuries involved a motor vehicle collision, respectively. For both age groups, in order of incidence, the three most common injured body parts were the face, head, and hands. The two most common locations of the injury were in the street (55.5%) and in the home (28.4%). Most injuries occurred during the summer months (in order of incidence, July, August, June). The transition from tricycle to bicycle provides an excellent time for a child to begin using a helmet. Federally approved bicycle helmets are effective in reducing head trauma, a major cause of death among young children. A study implemented an educational bicycle safety program for kindergarten-aged children and found that they were able to improve their knowledge of appropriate helmet-wearing technique (Cusimano et al., 2013).

Preschoolers, as passengers or pedestrians, are at great risk of an automobile-related accident. At this age, pedestrian injury is more likely to occur than is passenger injury. Preschoolers should be taught proper street-crossing techniques and, generally, should be supervised when crossing streets. Schwebel and colleagues (2012) discuss risk factors for child pedestrian injuries, which include developmental factors (cognitive and perceptual), distraction, temperament and personality, social influences (parents and peers), environmental risks, attention-deficient/hyperactivity disorder, and sleep and fatigue. The prevention strategies reviewed include parental instruction, school-based instruction (including crossing guards), street-side training, technology-based training, and community-based training.

Biological Agents

Preschoolers seem healthier than toddlers, with fewer illnesses of the

respiratory and gastrointestinal tracts. They have developed antibodies to many common organisms through exposure. Children usually become ill more often when they enter their first group situation, where they may be exposed to new organisms. This concerns parents and should be discussed by the nurse before the child begins attending a group setting. Increasingly, child care settings provide instruction to children about appropriate handwashing techniques to decrease disease transmission and provide relevant health-promotion teaching (Rosen et al., 2011).

Immunization recommendations are reviewed annually and updated with professional educational tools and parent-friendly resources. These resources for professionals and families can be found in a variety of formats, in both Spanish and English, at http://www.cdc.gov/vaccines/schedules/index.html. The American Academy of Pediatrics also publishes the most current recommendations annually, with a particular focus on the immunization needs of children. The 2012 recommendations can be found at http://www.healthychildren.org/english/tips-tools/pages/default.aspx#immunization-schedules. The child with a full course of immunizations as an infant receives repeated doses of diphtheria, tetanus, and acellular pertussis; measles, mumps, and rubella; and varicella vaccines between the fourth year and the sixth year (CDC, 2012). Many states require that all children in a school setting be fully immunized. Parents who choose not to immunize their children usually make this choice for religious reasons, but some parents worry about the risk of the immunization itself (Gilmour et al., 2011). Although vaccines provide an extremely safe way to combat communicable disease, issues about safety do arise. Individual health providers should develop their own strategies to impart evidence-based information, and participate in professional and public educational campaigns to disseminate the information widely (Gilmour et al., 2011). Because autism is often diagnosed around the same time a child is vaccinated, some parents have connected the onset of their child's autism with the vaccine. The American Academy of Pediatrics (2013) position statement refutes this association and

cites numerous studies that report no link between various vaccinations and autism (for more information see https://www.aap.org/en-us/Documents/immunization_vaccine_studies.pdf).

The risk of consequences of the disease itself far outweighs any vaccine risk, but without first-hand experience with vaccine-preventable diseases such as measles, *Haemophilus influenzae* type b, or polio, families today may minimize their severity (Diekema, 2012). Nurses must remain informed about recommended vaccines, their schedule, and their risks and benefits to provide accurate evidence-based information to families.

Nurses who remain informed about the reasons for avoidance of immunization will be better able to increase parents' understanding of the possible consequences of omitting a dose. Incomplete immunization may also occur as a result of parental forgetfulness or procrastination. Mandatory immunization for school entry provides an effective incentive for these parents. Although immunization rates are increasing, disparities exist in certain regions of the United States (Diekema, 2012). Advances on the horizon include more combination vaccines to decrease the cost of administration. Noninjectable vaccines that could be inhaled or eaten would greatly enhance pediatric immunization programs with ease of administration and simplified storage.

Continued efforts to vaccinate all children are needed, especially children living in poverty, particularly in large cities, where they are traditionally undervaccinated (Diekema, 2012; Gilmour et al., 2011). Nurses use immunization registry programs to consolidate records, to remind parents, to evaluate the person's scheduled program, and to analyze issues for a particular population. Registry programs avoid duplication and are of particular value for the preschool age group that may not be involved in day care or preschool with mandated immunization. The CDC publishes recommendations for individuals who have omitted doses for some reason. These alternative schedules are updated regularly along with the routine schedules and are available at the CDC website

(http://www.cdc.gov/vaccines/recs/schedules/child-schedule.htm). When immunizations have been omitted or delayed, the immunization schedule continues from the dose of the last vaccine. Parents should be fully informed about the potential side effects of immunizations. In most office and clinic settings, parents sign state-developed informed consent documents that describe potential side effects.

Chemical Agents

Preschoolers face exposure to environmental pollutants. The young child's skin area relative to body mass is twice that of an adult's, which increases the risk of toxicity. Environmental exposure has been implicated in the increased prevalence of learning disabilities because of the unique vulnerability of a child's brain to chemicals (Landrigan & Goldman, 2011; Trasande & Liu, 2011; Tucker, 2012). Disparities exist among populations with regard to their risk. Ethnicity, socioeconomic status, and geographical location all have an impact on the risk of exposure (Landrigan & Goldman, 2011).

In particular, lead poisoning and elevated blood lead levels continue to be an ongoing concern in children younger than 5 years. Health care professionals should perform targeted screening for lead poisoning in children who are Medicaid enrolled or Medicaid eligible, foreign born, or identified as high risk by the CDC location-specific recommendations or by a personal risk questionnaire (Box 19-10). A carefully collected finger-stick sample is an acceptable method for measuring blood lead levels. The CDC recommends that the threshold for follow-up and intervention for lead poisoning be a blood lead level of 10 mcg/dL or higher (Warniment et al., 2010).

Box 19-10

Lead Poisoning Screening Criteria

Screen children who meet any of the following criteria:

- All Medicaid-enrolled or Medicaid-eligible children at 1 and 2 years

of age

- All children who are identified as being at high risk on the basis of results of a personal risk questionnaire (if one of the following questions is answered "Yes" or "Don't know"):

- Does your child live in or regularly visit a house that was built before 1950 (this could apply to a home day care center or the home of a babysitter or relative)?

- Does your child live in or regularly visit a house built before 1978 with recent or ongoing renovations or remodeling (i.e., within the past 6 months)?

- Does your child have a sibling or playmate who has or has had lead poisoning?

- All refugees, recent immigrants, and international adoptees on arrival in the United States; repeat screening 3 to 6 months later for children 6 months to 6 years of age

- All children who are identified to be at increased risk by the CDC's state or local screening recommendations (i.e., high-risk zip codes)

In the absence of recommendations from the CDC, screen all children at 1 and 2 years of age, and screen children 36 to 72 months of age who have not been previously screened.

Modified from American Academy of Pediatrics Committee on Environmental Health. (2005). Lead exposure in children: Prevention, detection, and management. *Pediatrics, 116*(4), 1036–1046.

Lead is found in products used in folk remedies for many reasons. In the preschool group, lead may be found in products used to treat upset stomach *(empacho),* constipation, diarrhea, and vomiting. In Hispanic traditional medicine, these products, known as *greta, azarcon, alarcón, coral, luiga, maría luisa,* or *rueda,* may contain extremely high lead contents. Lead has also been found in traditional remedies from cultures other than the Hispanic group. For example, *ghasard,* an Indian traditional tonic, and *ba-baw-san,* a Chinese herbal remedy for colic, have also been found to contain lead. Sources of lead other than those found in traditional medicine include pottery, cosmetics, and food additives.

Chemical agents of concern for toddlers, such as pesticides, lead, and passive smoke, continue to merit consideration in the preschool population. Preschoolers, however, become more independent and understand the concepts of safe and poisonous.

More than 90% of US poisonings occur in the home (McGregor et al., 2009). Even though manufacturers enclose many children's medications in childproof packaging, the product may be administered incorrectly by the caregiver, or the child may experiment with another family member's colorful pills. For example, the medication used to treat attention-deficit/hyperactivity disorder, methylphenidate, poisons many children.

Many household products, drugs, carbon monoxide, pesticides, lead, mercury, polychlorinated biphenyls, ethers, and poisonous plants pose hazards to preschoolers. Secondary smoke and lead exposure represent negative chemical influences on the growing child.

Preschoolers should receive verbal explanations about poisonous or dangerous substances, but parents cannot rely on preschoolers to remember instructions. A poison control program from the University of Pittsburgh introduced a character called Mr. Yuk in 1971, and this symbol has continued to be used to increase awareness and access to poison control centers (http://www.chp.edu/CHP/mryuk). The ability to identify warning symbols such as Mr. Yuk helps preschoolers remain safe. Preschools and child care facilities often incorporate topics about environmental pollutants and dangerous substances into

their curricula to promote the health of preschoolers. Information about poison control is widely available on-line (http://www.aapcc.org/dnn/default.aspx). The toll-free National Capital Poison Center number is 1-800-222-1212. From that number the caller is directed to the nearest poison control center.

Parents should teach children about the four forms of poison, which are *solids* (air fresheners, pills, vitamins, aspirin, lipstick), *liquids* (cleaning products, fuel, alcohol), *sprays* (furniture polish, oven cleaner, room deodorizer), and *invisibles* (carbon monoxide, space heater fumes). Communication with parents about environmental dangers remains a major role of the child care provider.

Cancer

Cancer mortality in preschool children has declined in the past 20 years; however, disparities attributed to race, ethnicity, poverty, and lack of health insurance exist (Bhatia, 2011). Approximately one-fifth of childhood cancers occur in preschool children (CDC, 2016b). Most cancer deaths annually in children from newborns to 4 years of age are a result primarily of leukemia and brain/central nervous system, endocrine (primarily neuroblastomas), and soft tissue malignancies (National Cancer Institute, n.d.). Even though mortality has decreased, the incidence of brain and other central nervous system tumors has increased (Landrigan & Goldman, 2011). **Acute lymphocytic leukemia,** the most common childhood cancer, accounts for approximately one-third of the cases of cancer in preschool children (CDC, 2016b). Although less common than other solid tumors, **retinoblastoma** merits attention because of the possible loss of vision. Remarkable advances in long-term survival of children with cancer have occurred. Early detection remains the key to successful treatment; therefore early, aggressive efforts have been invested in detection programs. Some of the increases in the rates of diagnosis may be attributed to improved imaging techniques and early detection.

Leukemia

Leukemia (acute lymphocytic and acute myeloid) accounts for approximately 27% of the deaths in children (CDC, 2016b). The incidence of acute lymphocytic leukemia (ALL) rises from age 2 years, peaks at age 5 years, and diminishes through later childhood and adolescence. The dominant signs and symptoms of ALL appear suddenly, but often the child demonstrates a prodromal period of weakness, malaise, anorexia, fever, and tachycardia. Bone pain, petechiae, and hemorrhages after minor procedures such as dental extractions are encountered frequently. When an unexplained infection does not respond to management, suspicion should arise. Early detection and treatment of ALL has resulted in a marked increase in 5-year survival rates. Survival depends on the age at diagnosis, with the best survival rates occurring when diagnosis occurs during the preschool years (Hockenberry & Wilson, 2015).

With suspected leukemia, the nurse institutes secondary prevention strategies with an assessment that includes the following parameters:

- Examination of the cervical and peripheral lymph nodes
- Palpation and percussion of the liver and spleen
- Inspection of the skin for systemic signs of leukemia, such as pallor, purpura, petechiae, and **chloroma,** which is a localized tumor mass that has a greenish appearance and may be found in the skin, orbits, or other tissues in granulocytic forms of leukemia
- Inspection of the mouth for enlarged tonsils; hyperplasia of the gums; and red, friable gingivae
- Palpation of the sternum, bones, and joints for tenderness and pain

The rate of leukemia is higher in children with Down syndrome; therefore school nurses and public health nurses should monitor these children for early signs of the disease.

Wilms' Tumor

Most cases of **Wilms' tumor** occur in children younger than 5 years. A strong correlation exists between Wilms' tumor and several congenital

malformations. Genetic links may contribute to its occurrence in children with bilateral tumors and those who have family members with the disorder. When Wilms' tumor, aniridia (a congenital malformation of the iris of the eye), genitourinary malformations, and mental retardation occur together, the genetic association strengthens. However, survivors of Wilms' tumor that is unilateral at diagnosis possess a low risk of producing a child who will develop the disease. Information about the risk factors for Wilms' tumor is not definitive. The 5-year survival rates for children with this disease are excellent (Hockenberry & Wilson, 2015).

Retinoblastoma

Even as the most common intraocular tumor in younger children, retinoblastoma affects only 300 children younger than 20 years each year in the United States. Most of these children are younger than 5 years. Genetic mutations contribute to the incidence of retinoblastoma, usually causing the bilateral form of the disease. Even though the tumor is uncommon, the scientific work surrounding its diagnosis and management has resulted in many of the methods used for treatment of other cancers. Survival rates are excellent (Hockenberry & Wilson, 2015).

The history usually reveals a slow symptom progression. To determine risk factors, the following questions should be asked:

- Do tumors of the eye run in your family?
- If tumors of the eye run in your family, which relatives were affected and how were they treated?
- Have you noticed that your child has eye problems (crossed or lazy eyes or difficulty seeing)?
- Have you noticed any changes in your child's eyes?

Screening eye examinations for high-risk children include the following:

- Visual acuity
- Red reflex, which appears whitish with retinoblastoma (cat's eye

reflex)

- Ophthalmoscopic findings
- Lid lag, which is found with exophthalmos
- Strabismus, by doing the cover-uncover test

The cat's eye reflex and strabismus are the most common signs of retinoblastoma. Any suspicious findings indicate referral for further evaluation.

Neuroblastoma

Neuroblastoma, a cancer of the sympathetic nervous system, begins in the abdomen, primarily in the adrenal gland, approximately 70% of the time. The remaining 30% of cases originate in cervical, thoracic, or pelvic areas. Parodi and colleagues (2014) reported a connection between maternal characteristics and perinatal factors in patients with neuroblastoma. More than 90% of diagnoses occur by age 5 years. Unfortunately, many of the children have metastases when the cancer is identified. Frequently, symptoms of secondary distribution bring the child to the health professional. The survival rate for children in whom neuroblastoma is diagnosed during the preschool years is increasing, but in other age groups it has remained static. There is little convincing evidence of specific risk factors. Prenatal exposure to pesticides and hormones and use of certain medications suggest an increased risk (Landrigan & Goldman, 2011).

Cancer in a child can be frightening to parents, particularly if there is a strong family history of cancers of any kind. Early detection continues to be associated with increased survival rates. Secondary prevention programs should include the warning signs of cancer in children. Routine procedures, such as a bath, provide opportunities for parents to examine the child for physical symptoms of disease that are outlined in Box 19-11.

Box 19-11

Warning Signs That May Indicate Childhood

Cancer

Cancer remains a leading cause of death in children younger than 15 years, second only to injuries.

General

- Continued unexplained weight loss
- Persistent poor appetite
- Tires easily or lack of energy
- Tires constantly
- Noticeably pale

Leukemia or Lymphomas: "Liquid Tumors" (Cancer of the Blood, Blood-Making System, Lymph Nodes)

- Persistent fever (more than 2 weeks)
- Bruising without injury and purple or red patches appearing on the skin
- Swollen glands (lymph nodes) unrelated to infection
- Persistent bone pain or limping
- Paleness of the lips, skin, nails, or lining of the eyes

Brain Tumor

- Headaches, frequently with early morning vomiting
- Reflection in the pupil of the eye (eye tumor)
- Unexplained, persistent changes in behavior

Kidney Tumors

- Lump in the abdomen or abdominal enlargement
- Blood in the urine
- Bulging of the eyes
- Unexplained, persistent cough or chest pain
- A firm mass in the muscles

Make Bath Time Examination Time

- These complaints or physical findings should be interpreted only as warnings of possible serious disease. When these warnings are present, you should consult your physician at once.
- Do not forget that your children must be examined by a physician every year. The earlier cancer is detected, the better the chances are for a cure. With current treatment methods of surgery, radiation therapy, and chemotherapy (administration of anticancer drugs), the survival rate of children with certain forms of cancer has increased dramatically.

From Be Child Cancer Aware. (n.d.). Child cancer symptoms. Cancer Association of Greater New Orleans, New Orleans, LA. http://www.bechildcanceraware.org/child-cancer-info/childcancersymptoms.

Asthma

The incidence of **asthma,** a chronic inflammatory disorder of the airways, is rising more rapidly in preschool children than in any other group (US Department of Health and Human Services, 2011). The inflammation in this disorder contributes to a hyperresponsive airway, limited airflow, and respiratory symptoms that include breathlessness, wheezing, cough, and chest tightness. The causes

include genetic predisposition, allergens such as animal dander or dust mites, and nonspecific precipitants such as infections, exercise, weather, or stress. The rates for boys exceed those for girls, and the rates in the black and Hispanic populations exceed those in the non-Hispanic white population. Poverty contributes significantly to asthmatic illness, disability, and death (Azad et al., 2012; Tucker, 2012). Multiple factors contribute to exacerbation of asthma symptoms. High levels of exposure to tobacco smoke, pollutants, and allergens contribute. In addition to the generally known allergens of house mite dust and pet and rodent dander, cockroach particles have been implicated. Access to quality medical care, financial resources, and social support to manage the disease on a long-term basis exist in significantly different proportions from one population to another in the United States (US Department of Health and Human Services, 2011).

Determinants of Health

Social Factors and Environment

Some preschoolers become involved with groups outside their families, such as group child care settings, church groups, or family involvement in other activities, by age 3 years. Other children of the same age experience little outside contact. A preschool setting introduces the child to a wider social arena. Parents learn to release their child to encourage independent activity in a safe, supervised setting. Preschoolers test their independence, interactive skills, and self-discipline as they learn to function in a group. Preschool provides a transition to kindergarten and first grade, where group interaction skills are expected. Parents often select a preschool on the basis of geographical closeness to their home or a friend's recommendation, using the most practical approach (Box 19-12). With many child care facilities and options now available, parents frequently visit and evaluate a number of settings to determine the most appropriate for their needs (Bower et al., 2008).

Box 19-12

Evaluating a Child Care Setting

Child care that meets the needs and expectations of parents will most likely ensure a happy preschooler as well. The questions that parents should consider in evaluating and choosing a child care setting include the following:

- Will my needs and those of my child be best met with a caregiver in a family home, commercial center, or preschool, or by having a person come to my home to care for my child?
- What kinds of backup plans will I need or will be available if the provider becomes ill?

- What are my standards for nutrition, safety, sanitation, and health, and can these standards be met at the chosen child care facility?
- How important is it to my child to be with other children? How many children would be ideal for my child's socialization needs?
- What personality attributes and educational preparation do I desire in my child's caregivers? What attributes do I dislike, and how will I deal with these attributes to maximize the care given to my child? How important is caregiver stability to me? Can I comfortably communicate with the staff to collaborate with my child's learning?
- What educational philosophy do I want in the setting? What involvement do I wish to have in the educational mission of the facility?
- Do the hours of the facility meet my personal and professional needs? Is close access to my job or home important to me?
- How are the children grouped, and what is the caregiver-to-child ratio?
- Does the cost of the service meet my financial needs? Can I pay part-time fees during vacation or when my child is ill for a lengthy period?
- Is accreditation of the facility mandatory for me to use it?
- What is my internal response or my general feelings about the setting when I visit it before my child's enrollment? Are the caregivers interacting with and responsive to the children? Are the children happy and interactive? Are the children's individual needs addressed appropriately? Is the environment supportive of my child's care? Is discipline appropriate?

Culture and Ethnicity

Family cultural heritage continues to shape preschoolers. Health-promotion assessment should adapt to cultural differences (Box 19-13: Diversity Awareness). For example, a child who has never seen snow may not be able to know that it is cold. Unlike toddlers, preschoolers frequently ask why the family follows certain practices. These young children notice differences from one family to another. Their playmates may celebrate different holidays or practice family rituals different from their own. As preschoolers experience more activities outside their home, differences become more apparent. Discussion about the strength of cultural differences provides an excellent learning opportunity (Andrews & Boyle, 2015).

Box 19-13

Diversity Awareness

Preschool

Three groups of 36 Chinese children (each with a mean age of 61 months) were studied to identify cognitive abilities that might distinguish children at risk of dyslexia: teacher- or parent-reported (and health care professional–confirmed) language delay; family history of dyslexia; and not at risk.

The cognitive skills studied included syllable awareness, tone detection, rapid automated naming, visual skill, and morphological awareness. Compared with the control group, the language-delayed group of children scored significantly lower on all measures. Children in the familial risk group performed significantly worse only on tone detection, morphological awareness, and word recognition.

Testing these skills may be important assessment tools for diagnosing the risks of reading problems and may be associated with broader cognitive impairment as found previously in various Indo-European languages.

From McBride-Chang, C., Lam, E., Doo, S., Wong, S. W., & Chow, Y. Y. (2008). Word recognition and cognitive profiles of Chinese pre-school children at risk for dyslexia through

language delay or familial history of dyslexia. *Journal of Child Psychology and Psychiatry, 49*(2), 211–218.

Preschoolers also notice ethnic differences in appearance and pronounce skin colors, eyes, and hairstyles as "pretty" or "ugly." The socialization process forms presumptions similar to those of their family or playmates. Parents and caregivers who teach and role model positive behaviors allow children to see differences in others as being positive rather than negative. Mass media influences on physical attractiveness also contribute and become more significant to the adolescent.

Certain cultures apply more pressure for children to assume responsibility for younger siblings or household tasks. Confusion develops in preschoolers when the family's culture differs from that of most playmates. Disciplinary approaches differ from culture to culture. Uncertainty also results when parents integrate their cultural background into the community standards but the grandparents adhere to traditional cultural practices, rituals, and childrearing ideas.

Levels of Policy Making and Health

Many safety-focused legislative bills have affected preschoolers (see Chapter 18). School issues, as discussed in Chapter 20, also affect this age group. With current concern about health care costs, financial programs that focus on children may lose when competing with the whole of health care. If overall funding for vulnerable populations such as the homeless and the poor decreases, child health care in general in the United States suffers. In the United States, one in every four children younger than 6 years lives in poverty. Poverty is associated with homelessness, which places the child at greater risk of death and less participation in health-promotion and disease-prevention programs (Kerker et al., 2011). In addition, homeless children in the population-based study in New York City by Kerker and colleagues (2011) were less likely to have blood lead levels tested than the comparison populations in outlying metropolitan areas. These children were also more likely than those living outside the city

to have high lead levels (>10 mcg/dL). Homeless children had lower blood lead testing rates and a higher proportion of lead levels higher than 10 mcg/dL than did both comparison populations.

Economics

Poverty influences preschoolers as it does any child. Unlike toddlers, preschoolers become more aware of family economic status. A preschooler may know that the family lacks money for toys but recognizes less the comprehensive limits to resources that influence the family lifestyle. In some cases, the family's financial history prevents attendance at preschool or influences exposure to expanded learning activities. Preschoolers realize money acquires food, toys, and clothes, but they do not yet have a concept of economic values. The child might trade an expensive item for a trinket that looks more interesting. A child who uses the earnings to buy something realizes that more must be earned to buy more things. The child thus begins to learn the concepts of earning and spending.

Health Services/Delivery System

Access to health care resources for preschoolers is the same as that for toddlers. When preschoolers enter a school setting, admission may require that a health care worker screen them physically and developmentally. For indigent children, **Early and Periodic Screening, Diagnosis, and Treatment** (EPSDT), a Medicaid program, may fund the visit. Screening for individuals younger than 21 years who meet the economic criteria for Medicaid occurs in private offices, local health departments, and community clinics. Medicaid provides one screening examination per year, which includes the following elements:

- Medical history
- Assessment of physical growth, nutritional status, and mental development
- Inspection of ears, eyes, nose, mouth, teeth, and throat

- Vision screening
- Auditory screening
- Screening for cardiac abnormalities
- Screening for anemia
- Screening for the sickle cell trait
- Urine sampling
- Blood pressure reading
- Assessment and updating of immunizations
- Tuberculosis screening, when indicated
- Referral to a dentist for diagnosis and treatment for children aged 3 years or older

Referral for a complete physical examination addresses any health or developmental concerns identified during this screening. Eligible children receive EPSDT as a comprehensive service administered by Medicaid. Enactment of the Affordable Care Act in 2012 ensures health coverage for all children and free immunizations, affecting preschool children's health and health promotion (http://www.healthcare.gov/law/index.html).

Nursing Application

Preschoolers show much interest in the tools and procedures of a health screening examination (Price & Gwinn, 2008) (Box 19-14). These inquisitive children may play with the stethoscope, otoscope, and other diagnostic instruments. The nurse explains the tests in age-appropriate terminology and expects the child to cooperate for most of the visit. Preschoolers may show self-control during injections but definitely need a parent close by to offer support and encouragement. The nurse includes the preschooler in the history by directing questions about dietary intake and health practices, such as tooth brushing, favorite activities, and friends. At this age, children begin taking some interest in health, developing the cognitive maturity to learn many health-promotion skills that they will use for the rest of their lives.

Box 19-14

Health-Promotion Screening for Preschool Children

Annually

- Health history
- Height and weight
- Blood pressure
- Vision screening (age 3–4 years)
- Developmental and behavioral assessment
- Physical examination

Periodically

- Immunizations based on recommended schedule
- Ensure currency
- Diphtheria, tetanus, acellular pertussis
- Oral poliovirus
- Pneumococcal
- Measles, mumps, rubella
- *Haemophilus influenzae* type b
- Hepatitis B
- Varicella
- Hematocrit or hemoglobin level at least once after age 9 months
- Urinalysis at 5 years' old

Screenings for High-Risk Children

- Lead
- Tuberculosis
- Cholesterol

Anticipatory Guidance

- Injury prevention
- Child safety car seat (age less than 5 years) or seat belt

- Lap and shoulder belt (age 5 years or older)
- Use helmet and avoid traffic when bicycling
- Smoke detectors, flame-retardant sleepwear
- Hot water temperature less than 125°F
- Window and stair guards, pool fence
- Safe storage of drugs, toxic substances, firearms, matches
- Close availability of syrup of ipecac, poison control phone number
- Parents and caretakers trained in cardiopulmonary resuscitation
- Violence prevention
- Nutrition and exercise
- Limit saturated fats; maintain caloric balance; and emphasize grain, fruit, vegetable intake
- Regular fun physical activity
- Tobacco
- Effects of passive smoking
- Antitobacco messages
- Dental health
- Floss, brush with fluoridated toothpaste at least daily
- Regular visits to dentist

Case Study

Preschool Child: Ricky

Ricky, age 4 years, arrives in the clinic with his mother. Ricky lives with his mother and father, who both work full-time, and his infant sister. Their extended family lives in a different state more than 100 miles away. Both parents are of average height and in good health. Ricky's mother mentions that Ricky often expresses frustration, particularly in regard to food. Conflict over food occurs every day. Mealtime is a battle to get him to eat, unless his mother feeds him. Ricky's baby sister seems to tolerate all baby foods but requires her mother to spoon-feed. Ricky's mother is quite frustrated and concerned that he will become malnourished.

Reflective Questions

- What additional assessment information would you collect?
- What questions would you ask, and how would you further explore this issue with the mother?
- In what ways does the distance of the extended family influence this family's approach to health promotion?
- What factors would you consider to determine whether malnourishment is a factor in this family?

Care Plan

Ineffective Coping in Preschool Child: Ricky

***NURSING DIAGNOSIS: Ineffective coping related to parental feedback for regressive behaviors and lack of consistent limits and fulfillment of appropriate responsibilities**

Defining Characteristics

- Parent verbalization of need for help
- Changes in the usual behavior patterns of the child

Related Factors

- Inconsistent methods of parental discipline
- Inadequate impulse control
- Lack of social skills

Expected Outcomes

- The child will separate from his parents without incident (tantrum, crying).
- The child will join a community or church peer group activity.
- The child will perform one household task (picking up his toys) before bedtime every evening.
- The child will demonstrate independent self-care behaviors (feed himself).
- The parents will have clear, consistent, and age-appropriate expectations for behavior.
- The parents will explain the rationale for limiting a socially unacceptable or unsafe behavior as soon as it is displayed.

Interventions

- Discuss with the parents the process of growth and development and the child's need to learn how to compromise, take turns, and channel energy appropriately.

- Use a prescreening developmental questionnaire to validate general assessment data.
- Encourage the parents to leave the child in someone else's care while they go shopping or to see a movie.
- Encourage the mother to formulate a bedtime ritual with the child that does not include her sitting in his room until he falls asleep.
- Discuss with the parents and the child what “jobs” he can do at home and the expectation that they be performed daily.
- Suggest laying out the child's clothes so that he can dress himself. Set a time to be dressed, such as before or after a certain television program.
- Explore with the parents the availability of playgroups or community activities for the child.
- Encourage the parents to take the child to the neighborhood playground so that he can meet and play with other children.
- Have the child help around the house alongside his parents. Specify “work” and “play” times.
- Encourage the parents to praise the child for age-appropriate behaviors, being careful not to bribe him to perform.
- Discuss the principles of discipline consistency, immediacy, realistic expectations, and clear explanations.
- Recognize the parents' frustration and encourage them to try different approaches, such as limited choices, diversion, and incentives (“when you finish your meat, we'll play a game”).
- Suggest that the parents keep a diary of how long an approach was tried and how consistently the child responded.

- Discuss the decrease in appetite and reliance of food fads that typify the child's age. Review the principles of nutrition, timing of snacks, and ways of making food attractive to children.
- Refer the parents and the child to a nutritionist for nutrition counseling.

Evaluation

- Parents make appropriate verbal, nonverbal, and eye contact.
- Parents demonstrate correct caregiver techniques.
- Parents verbalize intent to maintain relationships.
- Parents attend routine well-child care appointments.
- Parents provide developmentally appropriate play activities.
- Parents describe healthy ways to express frustration.

---

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Schedules for preventive health care during the preschool years include visits at 4 and 5 years of age. Each visit includes an ongoing history; growth, physical, and developmental assessment; and discussion of age-appropriate developmental concerns.

In addition to the office or clinic contact, the nurse may consult with a preschool nurse or a nurse for a primary school and preschool. Early exposure to and reinforcement of health care information as part of preschool education lays a foundation for later healthy lifestyle habits, which influence overall societal health. Health as a curricular subject during the school-age years continues this focus. The school nurse's role in health promotion and prevention of illness is discussed in Chapter 20.

School-Age Child

Leslie Kennard Scott

OBJECTIVES

After completing this chapter, the reader will be able to:

- Identify expected physical and developmental changes occurring in the school-age child.
- Explore stages of cognitive development of the school-age child, particularly its relation to academic skills and performance.
- Appraise relevant health-promotion needs and common health risk factors found in the school-age child.
- Analyze cultural, societal, peer influence, and stress on development in the school-age child.
- Describe common developmental problems that occur in the school-age child including ways to assist parents in the management of these common problems.
- Determine strategies for family (parents) to improve child's self-concept, socialization abilities, and stress reduction in the school-age child.

Think About It

School-Age Bullying

Liam is 9 years old and has recently started demonstrating withdrawn behavior. His mother reports "he used to enjoy school." Recently, he has mentioned wanting to stay home from school and has become apathetic regarding participating in school-related activities. Two weeks ago, his mother reports she began driving him to school. "He hasn't wanted to walk to school with his friends lately. I don't understand what is going on; he tells me 'it's nothing.'" He was performing well in school until this most recent grading period. His teacher has voiced concern that Liam seems "distracted" and is not participating in group work conducted in class. Liam's father has voiced frustration that he seems to be "losing" things too. "Earlier this week he lost his backpack. Last week it was a jacket."

- Is Liam's behavior typical for a 9-year-old male child?

- How might a 9-year-old female child's behavior differ from Liam's in this situation?
- As a health care professional, how might you guide this family in finding ways to address Liam's behavior?
- How might you assist/counsel Liam on developing skills associated with resilience?
- Are there any further underlying issues that may be contributing to Liam's behavior?

"The school-age years" is a span of time between a child's entrance to kindergarten and the beginning of adolescence, a range from 6 to 10 years of age. During this period observable differences in growth, development, and cognitive ability are prominent. Consider how different the child entering kindergarten is from the preadolescent, particularly the differences in size as well as mental ability. Children grow (physically) much more slowly during this period as compared with growth during infancy and adolescence. Fine and gross motor skills are being perfected, and mental abilities grow tremendously as the child learns to read, write, and compute mathematics, in addition to other topics of interest (Table 20-1). Relationships outside the family, including **peer groups**, are also developing during this phase of growth and development.

TABLE 20-1

Growth and Development
Motor Development of the School-Age Child

Age (yr)	Gross Motor	Fine Motor
5	Dresses independently Runs well and jumps	Prints letters Ties shoes, buttons Draws triangle, square
6–8	Balances on one foot for 10 sec Can perform tandem gait Pedals a bicycle Is skilled in physical activities, running, skipping	Spreads with knife Holds pencil with fingertip Draws a person with three to six parts

		Cuts and pastes Aligns letters horizontally Knows right from left
8–10	Has good body balance Enjoys vigorous activities Has increased coordination	Spaces words and letters with writing Draws a diamond Has good eye-hand coordination Bathes self Sews and builds models
10–12	Balances on one foot for 15 sec Catches a fly ball May experience clumsiness from prepubertal growth spurt Possesses all basic motor skills similar to adult	Writes well Has skills similar to those of an adult

From Ball, J. W., Bindler, R. C., & Cowan, K. J. (2013). *Child health nursing: Partnering with children & families.* Upper Saddle River, NJ: Prentice Hall.

Most children are relatively healthy during this period. Health-promotion and health-maintenance strategies are important. During this period of development, children learn to accept personal responsibility and participate in the management of self-care tasks in the areas of personal hygiene, nutrition, physical activity, sleep, and safety. Nurses fill a significant role in the facilitation of parental roles and child roles in meeting growth, developmental, and self-care aspects of the school-age child (Centers for Disease Control and Prevention [CDC], 2015c; Goldfarb et al., 2011).

Biology and Genetics

A child's growth and development is influenced by genetic inheritance, nutrition, and the physical-sociocultural environments in which the child lives. The school-age child has an overall slimmer appearance as compared with the preschool child. Their legs are longer as compared with the rest of the body, allowing greater strength, balance, coordination, and fluidity of motion in running, jumping, climbing, throwing, and riding a bicycle (Goldfarb et al., 2011).

Most body systems reach adult level of function during the school-age years. Before 6 years of age, children use the diaphragm as the primary breathing muscle. After 6 years of age, thoracic muscles develop, and the respiratory rate slows to 14 to 24 breaths per minute (Moses, 2015). The school-age child's head circumference continues to grow. However, after age 5 years, head growth slows until **puberty**, at which time the head and brain reach adult circumference measurements (53–54 cm; 21 inches) (Goldfarb et al., 2011). The heart slowly grows in size, and the heart rate slows to an average rate of 60 to 160 beats per minute, approaching that of an adult. Mean blood pressure is lower in this age group than in adults and ranges from 95 to 105 mmHg systolic and from 57 to 71 mmHg diastolic (Moses, 2015). The gastrointestinal system is maturing with increased stomach capacity, resulting in less need for snacks and decreased calorie needs as compared with the preschooler. Bladder capacity increases. The immune system is better able to produce an antibody-antigen response (Durani, 2015). By puberty the endocrine system (with the exception of reproductive function) approaches adult capacity and function.

Elevated Blood Pressure

The long-term effects of elevated blood pressure, **hypertension**, in adults are well known and documented. The realization that adult

hypertension often begins in childhood has encouraged efforts to screen young children for elevated blood pressure. The American Academy of Pediatrics (AAP) and the US Preventive Services Task Force recommend that children have their blood pressure measured annually, beginning at 3 years of age (Moyer, 2013). This recommendation has transpired as a result of concerns of higher blood pressures in children in the past 2 decades, demonstrating risk of cardiovascular disease (Riley & Bluhm, 2012; Rodriguez-Cruz, 2015). Approximately 5 in every 100 children have higher than normal blood pressure (AAP, 2015b). Blood pressure among school-age children may differ greatly depending on the height and weight of the child.

Black American children and Mexican American children should be followed up closely because of earlier onset and end-stage organ damage in those with hypertension as compared with white children (AAP, 2015b; American Heart Association [AHA], 2014b; Riley & Bluhm, 2012; Moyer, 2013). A family history of hypertension or identification of an elevated blood pressure in a child mandates close monitoring and assessment of cardiovascular risk factors at well-child checkups during the school-age years (AAP, 2015b; Moyer, 2013). Differentiation between primary and secondary hypertension should be determined in any school-age child with elevated blood pressure (Moyer, 2013).

Physical Growth

Although many children have "spurts" of growth alternating with periods of minimal growth, height and weight growth velocities assume a slower and steadier pace as compared with earlier years of growth. The school-age child gains approximately 5 cm (2 inches) in height per year and 2 to 3 kg (4.4–6.6 pounds) in weight per year until puberty, at which time growth rates increase. (Lourenco et al., 2012). Black American children tend to be slightly larger and Asian American children tend to be somewhat smaller than their Caucasian counterparts, as plotted on growth charts that are believed to be standardized for various ethnic groups (World Health Organization, 2015a). Before the onset of puberty there is little difference in size

between boys and girls. However, toward the latter part of this developmental stage, girls tend to grow more rapidly in height and weight (Harding, 2015). A preadolescent increase in height and weight tends to occur at approximately 10 years of age in girls and 12 years of age in boys. However, maturation rates differ, resulting in a wide range of sizes in both boys and girls, particularly among those aged 10 to 12 years (Harding, 2015; Lourenco et al., 2012).

Black American and Mexican American children mature earlier than Caucasian children (Bordini & Rosenfield, 2011). Black American children are often taller and heavier than their Caucasian counterparts. They also tend to have longer and denser bones, slimmer hips, more muscle, and less fat on their limbs than on their central body as compared with Caucasian children (Medina-Gomez, et al., 2016). Girls tend to mature, enter puberty, and stop growing earlier than boys. From birth, girls tend to have more fat than boys, and after puberty girls have a greater percentage of body weight derived from fat. Adiposity has a direct correlation to puberty onset in girls, yet conversely relates to a delayed pubertal onset in boys (Bordini & Rosenfield, 2011).

School-age children tend to be concerned about their rate of growth, weight, time of menarche, and final height. These children need to understand that the timing and extent of their physical changes usually reflect their genetic inheritance. When one is assessing a child's height and weight, and before referring to **standardized growth charts**, the height of the child's family must be taken into consideration (CDC, 2010). For more information, see http://www.cdc.gov/growthcharts/. For example, the child whose height is in the third percentile may have parents who are shorter than average. Shorter height can be expected because of the family's genetic composition. Likewise, although the average age of **menarche** is at approximately 12.5 years in Caucasian girls and 12.0 years in black American girls, most girls experience their menarche at approximately the same age their mothers did (Bordini & Rosenfield, 2011). With sufficient body fat to stimulate hormones needed for menses, girls can have their first menstrual period between age 11 years and age 15

years and still be considered normal. As a result of better nutrition and differences in lifestyle, girls appear to experience menarche earlier than did girls of 30 years ago (Harding, 2015). Although the school-age child experiences numerous physical changes before adolescence, changes in three physical areas are of particular interest: oral development, lymphoid tissue, and motor skills development.

Oral Development

Teeth enable a person to speak, chew, and smile. They also help give the face shape and form. The school-age child appears to be constantly losing or gaining a tooth. Deciduous, or baby, teeth are usually lost in the same order in which they initially erupted. School-age children begin shedding their first teeth when they are approximately 6 to 7 years of age, and the process is complete with the loss of the second molars at 11 to 13 years of age. The first permanent teeth, the 6-year molars, erupt at 6 to 7 years of age and continue to erupt until the third molars (wisdom teeth) appear at approximately 17 to 22 years of age. The child aged between 6 and 13 years loses and gains approximately four teeth per year. A 13-year-old child should have 28 teeth, having lost 20 deciduous teeth (Peristein, 2013). When deciduous teeth erupt, only the crown is lost; the root has been reabsorbed in the developing permanent tooth. As the child's mouth becomes filled with the larger, permanent teeth, the shape of the jaw and the facial appearance normally change. Girls tend to experience earlier permanent **tooth eruption** than do boys (Peristein, 2013).

Dental problems, primarily **dental caries** (cavities), periodontal disease, and **malocclusion**, are among the most common health problems in school-age children today. It remains the most common chronic disease of children 5 to 17 years of age, four times more prevalent than asthma (CDC, 2014a). Present in up to 42% of children 2 to 11 years of age, untreated caries occur more frequently in poor and ethnically diverse children and in those who lack insurance or access to preventive dental care. School dental programs are necessary to educate school-age children on proper care and maintenance of their teeth. School-based oral health education programs and sealant

programs are in line with the ***Healthy People 2020* initiatives** and interventions for reducing dental caries among children (American Academy of Pediatric Dentistry, 2011; US Department of Health and Human Services [USDHHS], 2012a). In the past decade of *Healthy People* initiatives it has been determined that community-based and school-based sealant programs can reduce new cases of tooth decay by up to 60% for 2 to 5 years after a single application in high-risk children (CDC, 2014a). These programs demonstrate an area in which child oral health can be affected to improve the overall health of children in the United States.

The rapid change in the number and type of teeth and the uneven growth in the child's jaw may cause malocclusion, an unacceptable relationship of the teeth in one jaw to those in the other. Dentists evaluate children with overbites, gaps between teeth, and other alignment problems that may influence speech and eating (American Dental Association, 2014). Some children will grow out of these problems, but others may need **orthodontic care** and appliances (braces) to correct problems or improve their appearance. Peer reaction to braces is addressed as part of the teaching about body changes; this teaching may decrease problems with the child's self-concept or body image as a result of looking different. School dental programs include education about conscientious tooth care for the child who wears braces, because these frequently make brushing and flossing more difficult, especially for the school-age child who lacks manual dexterity.

Lymph Tissue

Lymph tissue grows rapidly throughout childhood, reaching maximal size before puberty, after which it begins to decrease in size, most likely as a result of changes in the concentrations of sex hormones. The amount of lymphoid tissue of a child up to 10 years of age often exceeds that of an adult (Kanwar, 2015). This is most often reflected in the size of the tonsils. As a result, tonsils that appear pathologically enlarged to a parent can be normal for the child's age. Additional lymphoid tissue during the school-age period generally helps this

group to have a stronger immune response than do younger and older children. This is a result of the immune system being activated by environmental antigens and exposure to common organisms (Kanwar, 2015).

Motor Skills Development

Neurological, skeletal, and muscular changes combine to increase the child's overall motor abilities. With maturation of the nervous system by age 7 or 8 years, the brain's two hemispheres articulate to allow the child more control over and coordination with motor tasks.

The child grows taller because of lengthening of the long bones that continues into adolescence. **Ossification**, replacement of cartilage with bone, occurs throughout childhood but is not complete until adulthood (National Institute of Arthritis and Musculoskeletal and Skin Disease, 2015). Therefore special attention must be paid to well-fitting shoes, appropriately sized chairs and desks, and backpack loads to avoid strain on an evolving musculoskeletal system (AAP, 2015a). Children at this age also need protective sports equipment and conditioning exercises before sports to prevent sports fractures (National Institute of Arthritis and Musculoskeletal and Skin Disease, 2015). However, the child builds new bony tissue during the entire period of childhood, which generally allows rapid healing of fractures. Overweight children typically have greater bone density as compared with their normal-weight peers. Although they have greater bone density, this does not translate into reduced risk of fractures and joint pain. Overweight children are more likely to experience bone fractures and have more joint and muscle pain than their normal weight counterparts (National Institute of Arthritis and Musculoskeletal and Skin Disease, 2015). The reason for this finding is not clearly understood at this time.

Muscle mass also increases with muscle strength. During the school-age years, physically active boys are slightly stronger than girls, but this difference is not significant until adolescence. With these changes the child has the potential to perform more complex fine motor and gross motor functions but must practice to perfect these

skills. Children willingly exercise their newfound skills and feel pride when others see their improved skill level when bike riding, tying shoes, and engaging in team sports, for example.

Gordon's Functional Health Patterns

The school nurse can be an integral and influential person for the school-age child. The school nurse provides the infrastructure for the health of the student. Gordan's functional health patterns can be used to comprehensively assess the school-age child.

Health Perception–Health Management Pattern

The school-age child understands an abstract definition of health and sometimes the factors causing illness, but this understanding differs from that of an adult. Most school-age children perceive symptoms and show an ability to participate in health-promoting behaviors. Health-promoting behaviors taught at school and home must meet the school-age child's cognitive level (concrete operation) and moral level (external rules and forces) to be effective. Teaching strategies using cognitive, psychomotor, and affective senses can help children learn responsibility for their own health (Shroff, 2015). This knowledge provides an excellent foundation for health-promotion behaviors during the school years.

School-age children's understanding of illness is directly correlated with their cognitive development and follows a direct sequence of developmental stages. It is important for nurses to integrate the child's developmental views on illness because this has direct implications for plans related to health education. When specifically asked about their ideas on causes of illness, school-age children usually state the germ theory, the punishment theory, or the external forces theory. Although many younger school-age children know that germs play a role in illness, they have limited understanding of how germs work (Brogan, 2015). They may believe that a misdeed or misbehavior caused their illnesses.

Various cultural influences may also contribute to a child's understanding of illness. Hinduism ascribes to the theory of karma (law of cause and effect). People create their own destiny by thoughts,

words, or deeds (Queensland Health, 2014). Illness, accident, or injury results from the karma one creates, and is often seen as a means of purification. Belief in the "evil eye," another cultural influence, occurs in many cultures and manifests itself in slightly different ways depending on where it arises. Most cultures believe that the victims are primarily babies or young children because they are so often praised and commented on by strangers. The evil eye is thought to be based on jealousy, and can have significant implications for the health of the victim (Queensland Health, 2014; Radford, 2013). This belief is strongest in Middle Eastern countries, Asia, Latin America, and Europe. Attempts to ward off the curse have led to the use of a number of **talismans** within the various cultures. It is important to be aware of such cultural and developmental beliefs of the school-age child when one is defining strategies for teaching health promotion.

School-age children face challenges in meeting health-promotion goals as defined by *Healthy People 2020* (USDHHS, 2012b). The *Healthy People 2020* initiatives present selected objectives related to this age group (Box 20-1: *Healthy People 2020*). However, people in the school-age child's life can facilitate societal attainment of these goals (Inman et al., 2011). Parents, caregivers, school nurses, and teachers teach health-promotion concepts, and they spend time monitoring and reinforcing preventive health practices, such as personal hygiene, dental care, and good nutrition. Role-playing, reading an age-appropriate books, and modeling of health-promotion behaviors (e.g., washing hands) may also help children make the link between behavior and improved health. Unfortunately, by imitating some caregivers, children can become passive health care consumers, asking few questions, doing as they are told, and perpetuating poor choices. These responses may also be caused by children's developmental and cultural obligation to obey authority figures. Parents, caregivers, school nurses, and teachers need to make commitments to demonstrate and teach healthy behaviors at home and in school; this helps children develop health values as part of their educational process toward reaching a healthy adulthood.

Box 20-1

Healthy People 2020 Health Objectives Related to School-Age Children

Selected National Health-Promotion and Disease-Prevention Objectives for School-Age

Oral Health

- Reduce proportion of children who experience dental caries in their primary or permanent teeth to 49% for all children in 2020. (Baseline is 54% of children aged 6–9 years in 1999–2004; current proportion, 2011–12, is 57.7%.)
- Reduce proportion of children 6 to 9 years of age with untreated dental decay in primary or permanent teeth to 25.9% by 2020. (Baseline is 28.8% of children aged 6–9 years for 1999–2004; current proportion, 2011–12, is 26.5%.)
- Increase proportion of children 6 to 9 years of age who have received dental sealants on one or more permanent teeth to 28.1% by 2020. (Baseline is 25.5% of children aged 6–9 years for 1999–2004; current proportion, 2011–12, is 37.6%.)
- Increase the percentage of school-based health clinics with an oral health component including dental sealants to 26.6% by 2020. (Baseline is 24.1% of schools offered sealants for 2007–08.)
- Increase the percentage of school-based health clinics with a topical fluoride treatment (including fluoride rinse/varnish) program to 32.1% by 2020. (Baseline is 29.2% of schools offered a fluoride program for 2007–08.)

Respiratory Illness

- Reduce hospitalizations for asthma among children to 8.6 hospitalizations per 10,000 children younger than 18 years by 2020. (Baseline is 14.9 hospitalizations per 10,000 children in 2007–08.)

- Reduce emergency department visits for asthma among children to 49.1 per 10,000 children by 2020. (Baseline is 56.4 per 10,000 children for 2007–08.)

- Reduce percentage of 5- to 17-year-old children who missed school because of an asthma attack in the previous year to 48.7% by 2020. (Baseline is 58.7% of children 5–17 years of age who had an asthma attack in the previous 12 months missed school in 2008; current proportion, 2011–12, is 59.1%).

Injury Prevention

- Increase percentage of children 8 to 12 years of age who use safety belts to 86% by 2020. (Baseline is 78% of children 8–12 years used safety belt in 2008; current proportion, 2011–12, is 79%.)

- Increase percentage of 6- to 17-year-old children using appropriate protective eye gear to 18.2% by 2020. (Baseline is 16.5% of children wore protective eye gear in 2008.)

- Reduce percentage of children exposed to any form of violence, crime, or abuse to 54.5% by 2020. (Baseline is 60.6% exposed to crime/abuse in 2008; current proportion, 2011–12, is 56.6%.)

Physical Activity

- Increase proportion of US public/private elementary schools that require daily physical education for all students to 4.2%. (Baseline of 3.8% schools required physical education in 2006.)

- Increase number of states that require regularly scheduled recess for all students to 17 states by 2020. (Baseline of seven states requiring

regularly scheduled recess in 2006.)

- Increase proportion of children from 2 years to twelfth grade who view television or videos or play video games for no more than 2 hours per day to 86.8% by 2020. (Baseline of 78.9% children 6–14 years of age viewed television or videos or played video games for more than 2 hours per day in 2007.)

- Increase proportion of children 5 to 15 years of age who walk to school (up to 1 mile) or bike to school (up to 2 miles). (New objective, no data.)

Nutrition

- Reduce the proportion of children and adolescents aged 6 to 11 years who are overweight or obese (defined as at or above sex-specific and age-specific 95th percentile) to 15.7%. (Baseline is 17.4% for 2005 to 2008; current proportion, 2009–12, is 17.9%.)

- Prevent inappropriate weight gain in children 6 to 11 years of age. (New indicator, no data.)

- Eliminate very low food security among children (target 0.2%) by 2020. (Baseline is 1.3% of households with children had very low food security in 2008; current proportion, 2013, is 0.9%.)

From US Department of Health and Human Services. (2015). *Leading health indicators.* https://www.healthypeople.gov.

Counseling the child and the child's family on a broad definition of health, one that includes personal and environmental health and safety, requires an awareness of the school-age child's normal perceptions of health (Inman et al., 2011). The school nurse, in consultation with teachers, is in a prime position to use such information to present content in a manner beneficial to the school-age child's level of understanding. Topics may include some of the following content areas: cultural difference of causes and management

of illnesses, causes of personal and environmental health problems, and critical issues affecting the school-age child's general health (e.g., backpack safety) (AAP, 2015a). All these issues may be integrated into general academic studies to establish a foundation for teaching prevention as well as help the school-age child develop advocacy skills to become an assertive health care consumer.

Nutritional-Metabolic Pattern

School-age children, like all people, need a well-balanced diet. An average of 1200 to 1600 calories per day is recommended to meet growth requirements (based on sedentary behavior) (AHA, 2015a). Usually these calories are consumed in three daily meals and one or two snacks. School-age children often eat foods low in iron, calcium, and vitamin C, and foods that have a higher fat and sodium content than foods their parents ate when they were this age. There is a disjuncture between current dietary practices and recommended dietary intake of children. These behaviors place children at risk of poor nutritional habits, obesity, iron-deficiency anemia, and chronic illnesses such as diabetes and hypertension (Klish, 2015). The school nurse can be an integral component and assume a leadership role in the education of school-age children on the health and cognitive benefits of consuming nutritional sound foods.

Factors Influencing Food Intake

Access to food, the influence of mass media, and contemporary busy lifestyles play a role in poor food choices. At the final review of the *Healthy People 2010* initiatives, up to 98% of American households were food secure throughout the year, surpassing the initiative target rate of 94% (USDHHS, 2012c). Federal food assistance programs are in existence to assist in the achievement of these initiative targets.

A multitude of television and billboard messages pressure children to eat certain foods, many of which contain large amounts of salt, sugar, and calories. These messages constitute the bulk of food commercials seen by children. Unfortunately, children are now being

exposed to more fast-food commercials than they were in 2003 (Powell et al., 2011). The majority of non–program content time is devoted to food-related advertisements. Frequent and lengthy watching of television and exposure to food-related advertisements have been linked to childhood obesity (Andreyeva et al., 2011; Zimmerman & Bell, 2010). In 2005 American children watched an average of 3 hours 19 minutes of television daily (Powell et al., 2011). In 2010, 50% of meals were eaten away from home, and one in five breakfasts were consumed from McDonald's (AHA, 2015b). These behaviors contribute to more "fast food" consumption and food of poor nutritional quality. On a typical day, 33% of children consume fast food (Demory-Luce & Motil, 2015). Healthy food often costs more and may be less accessible than unhealthy food (Yukhananov, 2011). Some cultures value food that has high salt and fat content.

Cultural factors, as well as food access, influence poor nutrition among the homeless and children in child care centers and may contribute to the high level of obesity, especially among Hispanic, black American, and Native American children (CDC, 2015d). These groups often lack access to safe and nutritious food. Thus successful interventions for school-age overweight and nutrition must focus on economic, social, and cultural factors that influence access to and use of food. School nurses are in a position to impact intervention strategies because of their familiarity with community needs, local cultural norms, and available resources.

Although some school-age children willingly try new foods, many continue to dislike vegetables, fruits, casseroles, spicy foods, and iron-rich foods and prefer a small range of foods. Some children may eat only raw vegetables and fruits and go through a phase of eating only one food at lunch, such as a peanut butter sandwich. These practices seldom hurt the child nutritionally.

Children frequently make their own after-school snacks and need supervision regarding the content. Daily consumption of foods high in vitamins A and C, fruits, and vegetables should be encouraged. With parental, caregiver, or teacher help and positive reinforcement, school-age children can learn to calculate nutrition needs, plan family

meals, and eat better for their overall health. These activities also assist school-age children in developing wise decision-making practices, feelings of empowerment about health, and healthy food habits for the rest of their lives.

American families have such busy lives that they eat few meals together. A positive environment for nutrition and socialization during a shared mealtime is important. Parents encourage positive food habits for each family member, and pressure to eat certain foods is avoided to prevent power struggles between the parent or caregiver and the child. A child's nutritional pattern usually reflects family patterns (Robson et al., 2016). For example, parents who skip breakfast tend to have trouble convincing their children to eat breakfast. Educating children as a group to eat healthy foods can be successful because of the powerful influence of a peer group (people of the same age, experience, and usually sex). The child whose friend is eating a candy bar usually prefers the same rather than an apple for a snack.

Nutrition Education

Nutrition education incorporated into the general curriculum of school-age children throughout their educational experience is important. Despite evidence that the school can serve as an environment for nutritional health-promotion education, not all schools require nutrition education from kindergarten through 12th grade (Cardoso da Silveria et al., 2013). School nurses and teachers, as part of core concepts usually taught in school, teach students about choices related to weight control and health and help them understand the role of the media and culture in nutritional choices (National Association of School Nurses [NASN], 2013). Teachers and school personnel also serve as role models for optimal eating and exercise habits for children in their charge. Lunch and breakfast programs exist in most schools and meet guidelines established by the US Department of Agriculture (USDA) (2013). Many of these programs continue in after-school programs and during the summer when school is out of session to support needs for quality food intake in 31 million US children (NASN, 2013; USDA, 2013).

The AAP and the AHA have established dietary guidelines for children and adolescents. The daily nutritional needs of a child who is 9 to 14 years old include the following (AHA, 2015a) (Figure 20-1):

FIGURE 20-1 Children 9 to 13 years old should eat two or more portions of vegetables and fruit totaling three to four cups daily.

- Milk group: 3 cups (24 oz total) of fat-free milk
- Meat group: 5 oz of lean meat or beans, or equivalent combinations of these foods
- Vegetable group: 2 to 2.5 cups of vegetables daily
- Fruit group: 1.5 cups of fruit
- Grains group: 4 to 6 oz daily, of which half should be whole-grain items (AHA, 2015a)

Overweight and Obesity

Overweight and **obesity** are major nutritional problems that have reached alarming proportions among adults and children in the United States. The Expert Committee on the Assessment, Prevention, and Treatment of Child & Adolescent Overweight and Obesity lists the following definitions for use in children and adolescents (CDC, 2015d):

- Individuals 2 to 18 years of age with a body mass index (BMI) greater than the 95th percentile for age and sex or a BMI exceeding 30 kg/m^2 (whichever is smaller) should be considered obese.
- Individuals with a BMI greater than the 85th percentile, but less than the 95th percentile, should be considered overweight.

The problem of overweight and obesity in children and adolescents has increased significantly in the last 50 years. Childhood obesity is now the number one concern for parents, surpassing drug abuse and smoking. One in three children are now considered overweight or obese (AHA, 2015c). Unfortunately, this demonstrates movement away from the *Healthy People 2010* initiative target of 15% (Klish, 2015). Evidence suggests that adult obesity begins in infancy or childhood and results from both genetic and environmental factors. For example, a child whose overweight parents constantly use food as a reward faces a greater risk of obesity than does a child of thin parents who do not reward the child with food. Excessive food intake and lack of physical activity also lead to obesity, and once overweight these children tend to exercise even less. Overweight occurs more in black American and Hispanic children than in Caucasian children (35%, 37.9%, and 30% respectively) (AHA, 2015c). These higher overweight and obesity rates may reflect less physical activity of black American and Hispanic children attributable to unhealthy living conditions and an inability to purchase higher-cost healthy food choices (Klish, 2015).

Overweight increases the risk of hypertension, diabetes, **sleep apnea**, orthopedic problems, and heart disease. Experts believe that overweight and sedentary behaviors are the primary risk factors for the development of insulin resistance, hyperlipidemia, hypertension, type 2 diabetes, and heart disease (AHA, 2015c; Nielson, 2011). There is also evidence that postprandial hyperinsulinemia may result in excessive weight gain (Klish, 2015). In addition, hormones released during the pubertal years make the situation worse in that these hormones cause the body to use insulin less effectively, leading to insulin resistance and thus increasing the risk of development of type 2 diabetes.

Current evidence suggests that overweight is associated with obstructive sleep apnea. Whether each disease state increases the expression of the other is unclear (CDC, 2015d). The potential association between short sleep duration and childhood overweight has been described in the literature (Bonuck et al., 2015; Box 20-2: Research for Evidence-Based Practice). Longer sleep durations are associated with higher degrees of activity, which may assist with weight loss. Recent findings support the proactive approach of ensuring adequate sleep in the prevention of overweight in children.

Box 20-2

Research for Evidence-Based Practice

Sleep Duration Relation to Overweight in Children

The purpose of this study was to better describe the association between short sleep duration or sleep problems with childhood overweight. Emerging research has introduced the association between sleep and the regulation of many physiological functions, including energy balance, appetite, and weight maintenance. The researchers sought to determine if the association of short sleep duration and overweight in children existed while controlling the data for measures such as quality of the home environment, parenting, and child behavior problems.

A longitudinal study of 785 children and their parents who were enrolled in the National Institute of Child Health and Human Development Study of Early Childcare and Youth Development was conducted. Data were collected regarding BMI, sex, socioeconomic status, and race in third and sixth grade students. Questionnaires regarding sleep and home environment were completed by the participant's mother at the same time intervals.

The findings revealed an association between short sleep duration in the sixth grade and overweight in the sixth grade. Shorter sleep duration in the third grade was independently associated with overweight in the sixth grade regardless of the child's weight in the

third grade. For every additional hour of sleep in the sixth grade, the child was 20% less likely to be overweight in the sixth grade. For every additional hour of sleep in the third grade, the child was 40% less likely to be overweight in the sixth grade. Sleep problems were not associated with overweight in children.

Adequate sleep duration in childhood may offer a protective effect on weight maintenance and overweight risk in children. One preventive approach to overweight in children may simply be to ensure adequate sleep in childhood.

From Lumeng, J., Somashekar, D., Appugliese, D., Kaciroti, N., Corwyn, R., & Bradley, R. (2007). Shorter sleep duration is associated with increased risk for being overweight at ages 9 to 12 years. *Pediatrics, 120*(5), 1020–1029.

The overweight and obese child faces ridicule by peers and discrimination later in life. These responses reinforce an already low **self-esteem** and poor body image and cause a cycle of personal isolation that influences a child's success, current and future (Griffiths et al., 2010, Klish, 2015). Helping the overweight and obese child change lifestyle patterns requires intensive intervention, including the support of parents. Even with these interventions, few overweight children achieve or maintain significant weight loss because of the complexity of factors (environmental, cultural, economic, and psychological) involved. In addition, there are reports that failure to maintain weight loss may be associated with impulsivity behaviors (Van den Berg et al., 2011). Some success has been achieved by programs that include implementation of reasonable caloric restriction; eating a variety of low-fat and low-cholesterol foods; and use of diet support groups, physical exercise, peer counseling groups, and habit changes (AHA, 2015b,c). However, intervention sometimes fails because some school-age children do not show concern about being overweight. Nursing suggestions for parents who are interested in preventing obesity in their school-age children are given in Box 20-3.

Box 20-3

Nursing Interventions to Prevent Overweight/Obesity During the School-Age Years

- Incorporate discussion of healthy food intake and daily activity into daily school life.
- Encourage parents to be a role model for their child—be active; plan physically active family outings.
- Make activity fun!
- Limit the amount of time spent watching television, playing video games, and using the computer/Internet.
- Discourage eating while watching television.
- Encourage parent(s) to consider cultural influences on dietary intake. Evaluate snacking habits and food choices. Balance healthy foods with ethnic food choices.
- Encourage the family to assess "fast food" consumption and explore/develop eating habits that support a healthier diet as defined by the food-guide pyramid.
- Encourage child to participate in food/meal selection and preparation.
- Support lunch choices that meet overall healthy nutrition intake.

Elimination Pattern

Most children have full bowel and bladder control by 5 years of age. Control involves the ability to undress and dress, to wipe and flush, and to clean hands. The child's elimination patterns are similar to the adult's, with urination occurring six to eight times a day and bowel movements averaging one or two times a day. For some school-age children, however, elimination continues to be a problem.

Enuresis

Involuntary urination at an age when control should be present is called **enuresis** (Kaneshiro, 2016; National Health Service, 2015). Children with primary enuresis have never achieved bladder control, and those with secondary enuresis have periods of dryness and recurrent enuresis. Involuntary nocturnal urination (bedwetting) that occurs at least once a month is defined as nocturnal enuresis, and wetting during the day has been termed diurnal enuresis. Enuresis should be considered not a disease but a variation of normal development. Enuresis affects 7% of boys and 3% of girls at 5 years of age (Goldberg, 2014).

Nocturnal enuresis causes disruption for both the child and the family. The child may frequently experience teasing from classmates and siblings. It can have profound effects on life socially, emotionally, and behaviorally. Although many forms of enuresis do not pose any significant health risk, there are social stressors. A night away from home appears impossible because of fear of wetting. Parents may be angry about the frequent bed changes and laundering and may try punishments, thinking that the child should be able to control the problem. Parental stress places additional pressure on the child, who may already have low self-esteem and lack self-confidence as a result of a perceived inability to control the problem (Pillinger, 2015).

Often because they lack information, frustrated families seek help. Many therapies exist yet require a high degree of motivation from the

child and parents. Their views must be taken into consideration when one is considering various treatment options. In addition to providing information, the nurse provides active support to facilitate coping. If a child does not have a urinary tract infection, various forms of management may be considered. These include wet alarm systems, bladder training and retention control, waking schedules, drug therapy, and hormone therapy. Each method has advantages, disadvantages, and cost considerations, but all require consistency and time from the child and parents, as well as positive reinforcement by the parents, to reach a successful outcome (Pillinger, 2015).

Diurnal enuresis is often called daytime dribbling. This term describes a urinary pattern most often seen in school-age girls. These children demonstrate "holding on" behaviors, including not voiding first thing in the morning, voiding only two or three times a day, and voiding exceptionally quickly (National Institute of Diabetes and Digestive and Kidney Diseases, 2012). It is not clear why children delay urination or empty their bladders only partially, thus promoting overflow incontinence. Evaluation of these children begins with a urine culture to rule out urinary tract infection. If no infection exists or symptoms persist after treatment, then the intervention is focused on increasing fluid intake to prevent "holding" and establishing a voiding routine of every 2 hours, with a conscious effort to empty the bladder completely. The nurse can be instrumental in helping the child and parents understand the problem and its management.

Encopresis

Another elimination problem that may occur in children is **encopresis**, defined as the persistent voluntary or involuntary passing of stool into the child's underpants after age 4 years. In most cases the problem has no discernible physiological cause and is not related to laxative use. There may be a history of inconsistent toilet training or early life stress in affected children. Encopresis is a common complication of chronic constipation. More than 90% of children with encopresis have a history of recent constipation and/or painful bowel movements (Barron, 2015). Once children become constipated or have hard and

painful stools, they begin to hold their bowel movements to prevent further pain. This creates a cycle that leads to fecal impaction and rectal distention. Stool then begins to leak around the impaction and leaks through the child's rectum, often without the child's knowledge. In most cases, soiling occurs during the day when the child is awake and active. Soiling at night is uncommon.

Encopresis is often associated with recurrent abdominal pain and, for many, enuresis as well. Often these children have emotional difficulties that began before or resulted from encopresis. They experience poor peer relationships and self-esteem, perhaps attributable to their offensive odor. Awareness of this childhood problem is necessary to appropriately identify the affected child, refer the child for treatment, and support the child and the family during a bowel management program and counseling.

Activity-Exercise Pattern

Physical activity in children is an important aspect of health and an integral component of health promotion. Childhood is considered to be a critical time in which regular physical activity behaviors are acquired and fostered (Figure 20-2). Generally, the school-age child is naturally active, although many do not meet current activity recommendations (CDC, 2015b; Craggs et al., 2011). Boys are typically more active than girls (Figure 20-3). In addition, those who perceive their neighborhood as unsafe or do not have at least one parent who exercises are less likely to exercise themselves. Physical activity and participation in sport activities tends to decrease with age, particularly among girls.

FIGURE 20-2 Peer play is important during the school-age years.

FIGURE 20-3 Boys are typically more active than girls.

As previously discussed, impressive changes in motor skills occur between the age of 6 years and the age of 12 years, allowing the child to engage in many activities that develop strength, balance, and coordination (see Table 20-1). Exercise typically occurs through group activities and organized sports such as Little League baseball and

soccer, through individual activities such as gymnastics and ballet, and through unorganized play such as bike riding, sledding, rollerblading, and imaginary play. Play provides important learning and health promotion, and for this reason should be encouraged consistently during the school-age years. For many children, involvement in physical activities is fun and connects them to their peers, family members, and other important people in their lives (Milteer et al., 2012).

Play activities also promote social, personal, and cognitive development. School-age children frequently prefer interacting with peers rather than with the family. This desire for peer interaction, usually with one of the same sex, extends beyond school and carries over to play and outside activities. A child's skill in motor tasks wins the respect of other children and provides a feeling of self-accomplishment (CDC, 2015e). Organized sports such as baseball teach team cooperation, competition, and other social skills. Concerns exist that young children have experienced too much physical and psychological pressure to perform in sports. This has generated a renewed commitment by many parents to focus more on the fun of sports than on the winning of games (Craggs et al., 2011). Organized activities such as Scouts and 4-H clubs teach children about group functioning, processes involved in performing a task, and the power of social relationships to create change. These lessons can prepare them for the discipline needed for a job later in life. Overall, children who perform well in these activities feel good about themselves, their competence, and enhance a sense of industry. Parents and teachers who compliment children when they perform well enhance self-esteem as well.

As part of play, school-age children incorporate new cognitive skills, including the ability to count and sort objects. Children of this age express pleasure in their collections of stamps, rocks, or other objects. Understanding the concepts of fair and consistent rules found in games requires cognitive skills of memory, logical reasoning, and the desire to work with others. Many children like to read, which provides ideas about life and cultures that differ from their own,

thereby enhancing their acceptance of human diversity. The nurse helps parents promote healthy play activities for children by encouraging the following (CDC, 2015e):

- Family activities that focus on physical activity and togetherness between parents or caregivers and children
- Use of a library card to encourage reading on a variety of topics and to teach responsibilities involved with borrowing
- Monitoring of daily television and computer use that detracts from physical activity and more active mental activities
- Encouragement of both group and solitary activities to support the child's overall development

Sleep-Rest Pattern

Sleep Patterns

Most school-age children have no difficulties with sleep. Generally, their sleep requirements and patterns are more similar to those of an adult than those of a younger child. Individual needs vary on the basis of activity, age, and state of health, but most school-age children sleep between 10 and 12 hours a night without naps during the day (American Academy of Sleep Medicine, 2014; Gupta, 2014). Unlike younger children, school-age children experience few difficulties with going to bed. Most children and parents can agree on a bedtime with some flexibility on nonschool nights and adhere to that agreement. When problems arise regarding bedtime, children may be testing parents who have not been clear and firm about their expectations for their children going to bed or have not been willing to discuss the arrangement with their children (Boyse, 2010). Although most Americans accept the idea that school-age children should sleep in their own beds, some black American, Hispanic, Chinese, and Japanese families may encourage the family or siblings to sleep together (Martin, 2013; Queensland Health, 2014). In the school-age child, bed-sharing does not have any impact on sleep patterns, nor does it show any long-term effects toward health, positive or negative

(Boyse, 2010).

Sleep Disturbances

The most common sleep problems that occur during the preschool and early school-age years are night terrors (see Chapter 19), **sleepwalking**, **sleep talking**, and enuresis. As a group, these disturbances have been called **disorders of arousal** (Boyse, 2010) and share the following characteristics:

- They occur immediately before a rapid eye movement state of sleep.
- Most occur 1 to 2 hours after going to sleep.
- There is a family history of sleep problems; boys experience more sleep problems than girls.
- Problems reflect normal central nervous system immaturity of the child.
- Problems may be influenced by fatigue and stress within the child.
- Problems do not involve the respiratory system.

Approximately one in six children (15%) aged between 5 and 12 years has sleepwalked at least once, but far fewer children walk in their sleep persistently. Sleepwalking is most likely due to the brain's inability to regulate sleep-wake cycles because of immaturity of the central nervous system. It occurs more often in boys and often occurs with enuresis (Gupta, 2014). Shortly after going to sleep, the child may suddenly sit up in bed, make repetitive finger and hand movements, or walk, usually for a short time. In most cases, however, the child stays in bed. The child may mumble when talking to a parent or other person (sleep talking). The words tend to be simple but unclear to the listener. Often the child falls back to sleep quickly after talking or walking (Boyse, 2010; Robinson, 2014).

Parents who are concerned about sleepwalking or sleep talking need to know that most children outgrow these episodes with central nervous system maturation. However, parents should protect their child from injury by placing gates at the top of stairs and removing sharp objects from the child's path. Most parents find that the easiest

solution is to direct the sleepwalker back to bed, where the child returns to a normal sleep. Occasionally, parents can intervene effectively by implementing relaxation techniques for their child before bedtime, avoiding stressful and fatiguing situations, and providing consistency with sleep preparation patterns (American Academy of Sleep Medicine, 2014; Boyse, 2010). If a child has many episodes of sleepwalking or sleep talking, or if parents express particular concern, he or she may need further evaluation and treatment by health care professionals.

Cognitive-Perceptual Pattern

The school-age child spends extensive time in settings that require mastery of new ideas and concepts. The child's basic **intelligence**, heredity, and environment encourage or discourage learning. Mastery of ideas and learning requires intact senses, such as vision, hearing, language, and memory capabilities that allow cognitive development and acquisition of skills needed for later life success (Goswami, 2015). Unfortunately, many children in society lack these capabilities and will have learning problems if these are not identified early through parental awareness, school observations, or routine health care assessments. For further information about school-age tests or procedural preparations, see http://www.nlm.nih.gov/medlineplus/ency/article/002058.htm (Kaneshiro, 2014).

Piaget's Theory

Piaget (2001) refers to the age span of 7 to 11 years as the period of **concrete operation**, a stage when children learn by manipulating concrete objects and lack the ability to perform thinking operations that require abstraction. During this time the child moves from egocentric interactions to more cooperative interactions and increased understanding of many concepts gained through environmental connections (Atherton, 2013). Children increasingly change their reasoning from intuitive to logical or rational operations (rule-

governed actions) and engage in serial ordering, addition, subtraction, and other basic mathematical skills. The operations of this period are termed concrete because the child's mental operations or actions still depend on the ability to perceive specific examples of what has happened. Older school-age children use both concrete and recently acquired abstract operations, which add flexibility and control to their thinking and meet developmental needs of adolescence. Unlike the egocentric preschooler, a school-age child begins to take the other person's point of view into account. This trait does not emerge suddenly. The new skill appears occasionally and then more frequently as the child's mental capacity and experience grow.

During the school-age period, the child understands a number of expanding concepts regarding objects, including the concept of **conservation** of substance (Atherton, 2013). When asked if a difference exists in the amount of liquid poured into two glasses of different shapes, the preschool, preoperational child focuses on the different shapes and says “yes.” The concrete operational school-age child realizes that no change has occurred in the amount of the liquid despite the change in shape. Conservation of numbers, weight, volume, and quantity, required to understand basic mathematics, sequentially develops as the school-age child gains chronological age and experience.

The concept of time also develops during this period. Children begin to learn to tell time and understand the passage of time. By age 8 years, most children understand the difference between past and present, and history becomes meaningful. The concept of human aging becomes increasingly understandable, and the child can comprehend the difference between an 18-year-old person and an 80-year-old person.

Two major operations of the school-age period are **classifying and ordering**. The child classifies or groups objects by their common elements and understands the relationship between groups or classes. For example, when given 12 wooden beads, some brown and some white, the child understands that the beads may be grouped by their color and by their material. Conversely, the preschool child focuses

only on one property of the beads, such as color. The newfound ability to classify objects shows in the school-age child's interest in collections, such as stamps or coins (Atherton, 2013). Children in school frequently "order" their world; they line up in school according to height, they repeat numbers and letters in their classic order, and they receive numbers in school to reflect an alphabetized surname. These two operations (classifying and ordering) must exist to learn to read, understand the concepts of numbers, and learn subjects based on relations, such as history (the relation of events in time) and geography (the relation of places in space).

Vision

The child's sensory abilities continue to develop during the school-age years. Visual capacity should reach optimal function by the sixth or seventh year (Heiting, 2015). Peripheral vision and the ability to discriminate fine color distinctions should be fully developed as well. Although many 4-year-olds have 20/20 vision, a school-age child should have a **visual acuity** of at least 20/30 in each eye, as measured by the **Snellen chart**, an assessment tool for children who can read some letters (Segre, 2015).

Physiological changes occur in the eye during the school-age years. Eyes in the preschool years are normally **hyperopic (farsighted)**, a condition in which the visual image of an object falls behind the retina. However, unlike older individuals, preschool children do not need glasses because their eyes normally accommodate by adjusting their lenses. For most children, vision becomes normal as the shape of the eye changes and lengthens with maturation. However, many school-age children need visual correction to prevent academic difficulties and headaches and dizziness when reading or doing close work. The peak incidence of hyperopia diagnosis in school-age children is at approximately 6 years of age (Castagno et al., 2014).

Twenty-five percent of school-age children have visual problems. Unfortunately, only approximately one-third of all states in the United States require children have an eye examination or vision screening before entering school (American Optometric Association, 2015).

Vision screening programs for schoolchildren are intended to help identify those children who have or may potentially have a vision problem that may affect physiological or perceptual processes of vision or that could interfere with school performance. Vision screenings are not diagnostic nor do they lead to treatment, but rather only indicate a potential need for further care. The school nurse is in an optimal position to ensure eye screenings are performed, and the nurse encourages parents of children with deficits to seek further optometric care to correct these defects so that these children can learn more effectively.

Two visual problems are common in the age group of the school-age child. Many school-age children inherit **myopia (nearsightedness)**, a condition in which the visual image of an object falls in front of the retina, causing the child to have difficulty seeing distant objects. The other condition, **astigmatism**, causes blurred vision because the image is focused poorly on the retina because of changes in the surface of the cornea or lens. Eyeglasses correct the defects, but the problem must be identified before it can be solved. For example, a child with myopia may not realize that his visual images are impaired. Children with corrective lenses often express delight and surprise when they first see the fully focused and rich detail of the world after experiencing less refined visual acuity for some time.

Hearing

The child's hearing ability (**auditory acuity**) is nearly complete by 7 years of age, although some maturation continues into adolescence. Hearing deficits occur less frequently than visual deficits, but hearing loss affects more than 1 million children from birth to age 21 years in the United States (American Academy of Otolaryngology, 2015a). This deficit compromises learning in school and important socialization with peers. **Chronic serous otitis media**, or long-term fluid in the middle ear, remains a common cause of hearing deficit in both the preschool years and the early school-age years (American Academy of Otolaryngology, 2015b). Fortunately, the reduction in the rates of otitis media in children met the *Healthy People 2010* initiative targets

(National Institute on Deafness and Other Communication Disorders, 2013). The success of meeting the targets of this initiative has been attributed to the introduction of heptavalent pneumococcal conjugate vaccine in 2000 (National Institute on Deafness and Other Communication Disorders, 2013). New concerns about the potential for long-term hearing loss in children who listen to loud music have been raised.

All school-age children, especially those with a history of recurrent ear infections or fluid behind the eardrum, should have periodic hearing evaluations (National Institute on Deafness and Other Communication Disorders, 2012). These are often performed as part of a health-promotion program in school and as required by many states. Various treatments exist for acute otitis media, including antibiotics and the recent discovery that xylitol gum may be of some preventive benefit (Azarpazhooh et al., 2011). Work continues on a vaccination for prevention of otitis media infections. **Tympanograms**, used to measure the sensitivity of the tympanic membrane to vibrations induced by pressure and sound waves, help detect and monitor this problem as part of well-child and ill-child care (American Academy of Audiology, 2011). By providing education on hearing protection for school-age children, the school nurse plays an important role in the maintenance of this important sense for the future.

Sensory Perception

Children learn simultaneously through many senses, and most teaching approaches incorporate this concept. For example, young school-age children see a letter, hear its sound, and feel its shape. With this approach, children learn in a number of ways to interpret an event (Willingham et al., 2015). For example, some children learn best by listening (**auditory learners**), others by doing (**kinesthetic learners**), and others by engaging all sensory modalities (auditory, kinesthetic, and **visual learners**). Because no two children have exactly the same sensory acuity, sensitivity, or discrimination, all children build slightly different perceptions and conceptions of the world around them and do not follow the same timetable to grasp

concepts. Therefore teaching approaches must be individualized to meet the learning needs of most children.

Of all the senses, visual perception has been studied the most, primarily because of its role in helping children learn to read. Studies have examined children's abilities to discriminate parts of a picture (to see a figure within a picture). Children usually progress from the preschool stage, during which they perceive visual stimuli more as a whole, to the school-age stage, during which they perceive more details, and finally to the point at which they perceive and integrate both. This process helps children recognize letters, the first step needed for reading. Children may first be able to differentiate between obviously different letters, such as “h” and “o,” but may have difficulty with letters similar in appearance, such as “b” and “d,” until they can distinguish details more effectively.

Language

Language develops rapidly during the school years. Most school-age children enter this period with an ability to understand and speak a language, but with only a basic knowledge of reading and writing. By the end of the school-age period, most children have acquired at least a functional ability in both areas. Language development mandates that a child have visual perception for reading, auditory acuity and perception for understanding spoken language, and fine motor skills for both articulation and handwriting.

The full capacity to imitate sounds develops during the childhood years. Between 6 and 7 years of age, the child shows the ability to produce proper articulation for most vowel and consonant sounds. However, some have difficulty expressing sounds for “s,” “l,” “z,” “sh,” “ch,” and “r”. By 7 years of age the child should be able to articulate all sounds for speaking, and by age 12 years has a vocabulary of approximately 4000 words. Understanding of the syntax (grammar) and semantics (meaning) of language continues to develop. The child uses more complex sentences and understands multiple meanings for the same word and metaphors. The child should be able to recognize and correct spelling and grammatical

errors by 8 or 9 years of age. The capacity to learn foreign languages is at an optimal level at this stage and provides the rationale for foreign language instruction during the school-age years. Foreign language instruction also provides children with information about other cultures and an opportunity to understand people who are different from themselves.

Much of the child's time in school focuses on learning to read and write. Learning to read is a complex process, beginning with letter and sound recognition (AAP, 2015c). Letters combine to form words that the child must learn to decode. Words combine to form sentences, and so on. Most children need help from teachers, peers, parents, or older children to learn to read effectively. Some researchers believe that children learn best by sounding out the individual letters of a word (**phonics**), whereas others think that learning the word as a whole unit is better. Both processes have value, and likely a combination of both is most effective (AAP, 2014). Considering the wide range of processes that support development of reading skills (conceptual, perceptual, verbal, and motor), it is not surprising that most children experience some difficulty in learning to read (AAP, 2014).

Handwriting requires eye-hand coordination, motor control, and perceptual abilities (Harron, 2014). Primarily a motor skill, handwriting does not reflect mental capacity. Many bright children and adults have poor handwriting, and vice versa. Boys tend to have more problems with legible handwriting than do girls. Writing style does not approach adult-level maturity until the end of late childhood, but the handwriting should reflect the child's handedness. No reversal of letter outlines should occur by age 7 or 8 years, and the relative size of letters should be uniform. By age 8 or 9 years, letter strokes should be firm, even, and flow with ease. The individual who has difficulty with handwriting may use a typewriter, computer, or graphics to produce a satisfactory written product. Tutoring by a handwriting specialist can help children with **dyslexia**, a term defining the tendency to reverse the normal appearance of letters and numbers in writing.

Memory

Memory abilities, both short term and long term, improve for school-age children. Strategies such as organizing, classifying, and labeling information help them retain information. Rehearsal, repeating an item to be learned, is also a helpful memorization strategy. At age 5 years, children use rehearsal when someone suggests or models it; at age 10 years, they rehearse spontaneously. Memory abilities improve with practice and through various strategies, such as placing the words that need to be remembered in a song or by rhyming words (Raghubar et al., 2010).

Intelligence

Intelligence tests assess a person's mental abilities and compare them with the abilities of other people through the use of numerical scores. Although the term intelligence is used as if there is agreement on what it means, in reality there is much debate as to how this term should be and has been defined. For example, debate has surrounded whether intelligence should be considered an inherent cognitive capacity, an achieved level of performance, or a qualitative construct that cannot be measured. Psychologists have debated whether intelligence is learned or inherited, culturally specific or universal, or one or several abilities (Kendler et al., 2015). Although these debates are ongoing, evidence is increasing that traditional intelligence tests measure specific forms of cognitive ability that are predictive of school functioning but do not measure the many forms of intelligence that are beyond these more specific skills, such as music, art, and interpersonal and intrapersonal abilities.

The concept of intelligence usually conveys an ability to think and process information learned earlier in life. Scores on an intelligence test should measure the child's basic abilities as compared with those of others of the same age and experience level and, ideally, should predict performance in school or society. However, this is not always the case. Intelligence test scores tend to differ because each test, or each form of the same test, measures slightly different samples of

abilities and reflects the test author's philosophy on intelligence. It is important to note that some intelligence tests may be culturally insensitive (123test, 2012). For example, the protectionism of the Asian culture may cause lower test scores on self-help skills and socialization among Asian children, who demonstrate in other ways that they are good students. Furthermore, words on the test may not be part of an ethnic group's usual vocabulary, causing children to miss these items on an intelligence test.

Children also take achievement tests that measure the amount of information learned in a specific area and offer insight into a child's overall intelligence. Although intelligence and achievement tests should measure different issues (basic ability versus learned achievement), their results correlate well. Some researchers believe this correlation exists because both tests actually measure the same thing (achievement, notability).

Reports from intelligence and achievement testing differ. Intelligence tests usually provide a number that represents **intelligence quotient (IQ)**. An IQ of 90 to 110 is considered average (BMJ Best Practice, 2015). Achievement tests compare the child's performance with that of other children and report scores as percentiles. For example, a score in the 20th percentile of a test means the child scored better than only 20% of other children of the same age in that skill. Current beliefs accept that people inherit some of their intelligence but that environmental factors also influence opportunities for learning and overall intelligence. Most likely the greatest environmental influence is socioeconomic, reflected in the correlation in scores: children from low-income families tend to score lower on intelligence tests than do children from middle-income or high-income families. The reason for this probably relates to many subfactors, such as nutrition, language, parental reinforcement and encouragement, and sociocultural environmental stimuli. Social programs such as the federal Special Supplemental Nutrition Program for Women, Infants, and Children and preschool stimulation programs such as Head Start have attempted to address these subfactors to improve the potential of young children from diverse

populations. Many people have suggested less focus on IQ tests, primarily because they label children early in life and influence, often negatively, their self-perception and their performance.

Learning Disabilities

Educators estimate that 10% of children 6 to 17 years of age have a **learning disability** (Child Development, 2015). Many terms and definitions have been used to describe the impairments of children who have normal or above-normal intelligence and usually do not have visual, hearing, or motor handicaps or emotional problems yet have difficulties in school learning (Disabled World, 2015). Some children have minor, almost unnoticeable difficulties, whereas other children are so impaired that they appear to be mentally retarded until their impairment has been diagnosed and they have been helped. An individual child may have more than one developmental disorder. Some children will develop behavior and self-esteem problems as a response to their inability to function satisfactorily (BMJ Best Practice, 2015).

One well-known condition that causes difficulty in the child's adjustment to the school setting is **attention-deficit/hyperactivity disorder** (ADHD), a disorder that reflects developmentally inappropriate degrees of inattention, impulsiveness, and hyperactivity (AAP, 2011a). ADHD is the most common neurobehavioral disorder of childhood and among the most prevalent chronic health conditions affecting school-age children. Frequently these children have high energy, intuitiveness, and creativity, personal characteristics that help them succeed in some facets of their lives. Despite diagnostic criteria for ADHD developed by the American Psychiatric Association (2013), the problem has been difficult to assess, primarily because the child manifests symptoms in varying degrees in different settings and with different people (Box 20-4). Some symptoms associated with ADHD have been identified as changes to the *DRD4* gene (Dadds et al., 2016). Treatment of children with ADHD has been controversial but includes behavior management, family counseling, classroom management, nutrition therapy, and medication (Devore & Schutze, 2015b). These

interventions may also be successful in management of ADHD-affected adults. However, with the use of **genomics**, new treatments and therapies may be developed to better match the needs of the individual with ADHD (Dadds et al., 2016; Box 20-5: Genomics).

Box 20-4

Diagnostic Criteria for Attention-Deficit/Hyperactivity Disorder

Consider a criterion is met only if the behavior occurs more frequently than that noted in most people of the same mental age as the child.

- A disturbance of at least 6 months exists during which at least six of the criteria for either inattentive behavior or hyperactivity-impulsivity behavior are met (for specific criteria, see American Psychiatric Association, 2013).
- Some inattentive or hyperactive-impulsive symptoms that caused impairment existed before age 7 years.
- Some impairment for the symptoms exists in two or more settings (at school or at home).
- Clear evidence of clinically significant impairment exists in social or academic functioning.
- The symptoms do not occur only with a pervasive developmental disorder, schizophrenia, or other psychotic disorder and do not support another mental disorder (mood disorder, anxiety disorder, dissociative disorder, and personality disorder).

Genomics

Medicine in Children

Clinical genome sequencing and exome sequencing technologies are becoming promising tools for determining genetic causality of numerous diseases in children, including cystic fibrosis, asthma, autism spectrum disorders, and childhood cancers. Genomic medicine is looking to find genetic mutations that drive various disease states so as to yield new targets against which novel therapies may be developed (Downing et al., 2012). The next generation of medical treatments and therapies are being designed to better improve outcomes for many childhood conditions. Nurses are well positioned to incorporate genetic and genomic information across all aspects of health care. This translation of clinical, medical research technologies into practice is not without challenges (Thiffault & Lantos, 2016). However, nurses have an opportunity to close the gap between research and therapeutic developments.

From Downing, J. R., Wilson, R. K., Zhang, J., Mardis, E. R., Pui, C. H., Ding, L., et al. (2012). Pediatric Cancer Genome Project. *National Genetics, 44*(6), 619–622; Thiffault, I., and Lantos, J. (2016). The challenge of analyzing the results of next-generation sequencing in children. *Pediatrics, 137*(Supp1), 83–87.

The nurse's role with the child who has a learning disability is varied. The nurse may participate in detection of the problem and consultation during evaluations, collaborate with the school administration on implementation of a treatment plan and referral to resources, assist as a liaison between school and home environments, and be a source of instruction for both the child and the family to improve overall development and the family's adaptation to meet the needs of this unique child.

There are two laws protecting children with disabilities, including those with ADHD: the **Individuals with Disabilities Education Act (IDEA)** of 1997 and **Section 504 of the Rehabilitation Act of 1973,**

Amendment Act of 2008 (Wrightslaw, 2015). The IDEA is a special education law, whereas Section 504 is a civil rights statute. Both guarantee qualified students a free and appropriate public education and instruction in the least restrictive environment. This means that students are to be instructed among those who are not disabled and to the maximal extent appropriate for the student's needs.

The nurse plays a vital role in promoting the school-age child's overall cognitive and perceptual health, helping to prevent problems in these areas. The nurse must talk to parents and school administration personnel about any child who has language articulation problems beyond 6 or 7 years, because this child should be evaluated by a professional. The nurse helps parents understand their child's level of cognitive and sensory abilities so that learning expectations are realistic. Through educational materials sent to the child's home or provided during school meetings, the nurse may address the **socialization** needs and development of school-age children. The nurse also needs to help parents understand common tests used for child intelligence and achievement screening (Atherton, 2013). In addition, the nurse helps evaluate a child believed to have a learning disability when the child may actually have a health problem, general immaturity, or an environmental deficit (poverty or divorce; Krause-Parello & Samms, 2010).

Self-Perception–Self-Concept Pattern

Through each of the developmental processes of physiological growth, cognitive development, and social development, children progressively engage in an important process of **self-discovery**. Through these processes, children actively build and create their own personalities, develop relationships with others, and expose themselves to a wide range of experiences that influence their behavior, attitudes, and values.

Erikson's Theory

The stage of personality development described by Erikson for the

school-age child is **industry versus inferiority**. The major task to be accomplished is full mastery of whatever the child is doing (sense of industry). The child focuses on success in personal and social tasks and avoidance of a sense of inferiority. Inferiority occurs with repeated failures at attempted tasks and with little encouragement or trust from people important to the child. With mastery of the tools of the culture in relation to those of the peer group, a sense of worth and understanding of the self develops (Erikson, 1993, 1994).

Self-Concept

Self-concept develops over time and through a variety of experiences and relationships. For example, by being responsible for a pet's care and by showing love to this animal, the older school-age child nurtures a positive self-concept. The way in which others, especially peers, view the child influences the sense of self (Ferrer & Fugate, 2014; Sturaro et al., 2011). Increasing cognitive abilities facilitate better understanding of the identifying factors of others (race, ethnicity, disability, or gender) and how those others compare with the child. Self-concept includes self-esteem, sense of control, and body concept.

Self-esteem.

Self-esteem has been defined as the extent to which an individual believes oneself to be capable, significant, successful, and worthy (AAP, 2015d). The younger school-age child has a limited self-concept, but one that develops with successful completion of the tasks of this period (Erikson's sense of industry). Although engaged in more activities outside the home, the child still depends on the family, as defined by one's culture, to develop high self-esteem. In school, teachers or group leaders frequently reward those who have succeeded in a task with badges, stars, or privileges (tangible objects that validate success).

The peer group's influence on the school-age child's self-esteem is unquestionable. Acceptance by a peer group contributes to feelings of self-worth and a sense of belonging to a desired group. Competition or collaboration with peers in school, clubs, and activities also

influences feelings of adequacy and feelings of success (Women's & Children's Health Network, 2013). Parents must be encouraged to expose their school-age children to interesting activities of their choice, involving peers, to nurture their self-esteem and sense of uniqueness.

Concern has been voiced about school-age girls suffering a decline in self-esteem that affects their school achievements. Some research indicates that boys receive more praise in school than do girls, and girls receive criticism on the content of their work, whereas boys receive more criticism on the appearance of their work (Garey, 2015). Girls experience greater competition now than in earlier times, and they face pressures about personal appearance, particularly if they are white. Various authors report that girls need strong adults to support their ways of thinking and behaving in a world often built on "male values." Girls tend to have high self-esteem if they perceive parental harmony that supports perceptions of balance within themselves and promotes their emotional health (Garey, 2015).

In encouraging development of self-esteem in all school-age children, the nurse remembers that a child needs to experience success with tasks, and completely structured activities may not provide this opportunity for some children. A child who succeeds in some things and receives acceptance by peers gains a sense of competence and worth, is self-confident, and has high self-esteem, which are important qualities for life survival.

Sense of control.

As the school-age child matures and makes choices, a sense of control develops about the self and the environment. Children with an internal locus of control believe they are responsible for their behavior and accomplishments and tend to have higher levels of achievement than do children who believe in an external locus of control. The latter think that fewer reasons exist for them to try hard at a task, because others or fate determines life results. Hispanic and black American cultures may more often support an external locus of control based on a strong belief that God determines one's outcome (Tynan, 2015).

Older children and girls tend to have a more internalized locus of control than do younger children and boys.

Body concept.

The school-age child's concept of the body and its functioning also changes from the preschool period and adds to overall self-concept. By age 8 to 11 years, children know that parts of the body constitute a related whole. The 11-year-old child can name twice the number and functions of internal body structures that a 6-year-old child can and frequently understands the functions of the cardiovascular, musculoskeletal, and nervous systems. For example, the 7-year-old child knows that the heart is important and that it beats, whereas the 13-year-old child knows that the heart pumps blood. Changes or differences in the body may frighten the school-age child until the child understands normal developmental processes, such as losing deciduous teeth. Physical differences, such as freckles, can provoke ridicule and isolation. Children in this age group frequently feel threatened by others with deformities. Children with chronic illness worry that their peer relationships will be negatively influenced if others know about their illness. Children who learn about body differences, by meeting people with chronic health problems as well as by reading and discussion of anxiety about differences, increase their knowledge of the body and ways to maintain health. They also gain an understanding of the value of each person, despite their differences.

Roles-Relationships Pattern

The family environment provides a sense of security that allows the school-age child to cope with uncertainties in the external environment. Although many live in single, divorced, mixed-race, or same-sex parenting households, the family structure generally encourages a child's cognitive growth through exposure to a variety of experiences that bolster the desire to achieve and develop positive self-esteem.

Parents, caregivers, and children interact in a variety of ways to

show love and companionship for each other. Caregivers, such as grandparents or extended family members, protect the dependent child and teach the learning child. The caregiver-child relationship is not equal, primarily because caregivers and parents serve as authority figures that establish the rules needed for the functioning of the family and safe growth of the child. During the school-age years, the child's increasing maturity, independence, and responsibility begin to reduce the amount of parental authority and structure needed. In some cultures, parents set higher standards for child independence than parents of other diverse populations (Women & Children's Health Network, 2013). With increasing independence, the child prioritizes school and peer group relationships to develop socialization skills and understand group social mores (Sturaro et al., 2011). These connections will help prepare the child for future relationships.

School-age children also begin to broaden their interests outside the home, often encouraged by parents. Unfortunately, some older children may become involved in gangs, behavior that causes much stress for both children and their parents. The child's changing world frequently alters family schedules and patterns, supporting studies that have found that parents express the least amount of parental satisfaction when their oldest child is between 6 and 13 years of age. The relationships between siblings differ, depending on birth order, culture, sex, and age differences and perceived power of siblings. Siblings interact with one another in a number of roles, such as playmates, teacher-learner, protector-dependent, and adversaries, based on feelings of jealousy and rivalry that often occur in families. School-age children cope with these feelings better than do preschool children because they have outlets outside the family, including school and friends. Parents can minimize conflicts by recognizing each child's needs and level of maturity and by providing guidance and support.

As children mature, they assume more responsibilities within the family and the community. School-age children learn responsibility for allowance, household chores, self-care, and pets and acquire a sense of empowerment as an integral part of the family. This is the

period during which families often give allowances or children earn money through chores or small jobs, such as paper routes. The amount of an allowance may relate to cultural values. In one study, Asian children earned higher allowances than did other children from diverse population groups for completing fewer chores and for meeting higher standards of academic performance (Goldstein & Brooks, 2012). School-age children learn valuable life lessons by earning and spending their allowances.

Children learn socially accepted behaviors when their parents engage in **limit setting** (defining expected behavior and consequences when limits are not honored). Violent behavior must be discouraged, and nonviolent methods to reach resolutions for personal problems should be encouraged (Box 20-6). Parents who express their feelings, explain why things happen, and listen to their children while setting limits encourage the development of self-control and positive self-esteem. Some families with school-age children find it helpful to have periodic family meetings during which everyone discusses family issues, rules, and responsibilities. Behavior contracts between the parent and the child provide direction and may also encourage improved behavior by delineating favorable consequences when the terms of the contract are followed.

Box 20-6

The School-Age Child: Points for Effective Discipline

Effective discipline is essential to family harmony and individual child growth and reflects cultural beliefs. The goal of discipline is to encourage and reinforce positive child behaviors, eliminate inappropriate child behaviors, improve parent-child communication, and meet parental needs. Effective discipline requires these essential components: a positive, supportive, loving relationship between the parent and the child; use of positive reinforcement strategies to increase desired behavior; and removal of reinforcements or application of punishment to reduce/eliminate undesired behaviors.

Specifics of discipline strategies include the following:

- Ignoring the misbehavior and acknowledging the appropriate behavior
- Using distraction or substitution to avoid a problem situation
- Offering choices to prevent inappropriate behavior such as whining or emotional outbursts
- Using humor to decrease the intensity of a situation
- Modeling the appropriate behavior
- Setting age-relevant limits
- Giving specific and clear commands for behavior appropriate to the child's age
- Talking calmly, being a good listener, and encouraging negotiation, perhaps in a family meeting, to promote problem resolution
- Limiting a child's environment (distractions such as music and television)
- Setting clear and consistent consequences for misbehavior (withholding privileges, using contracts)
- Providing one-to-one time, focusing on positive attention
- Taking time for oneself to replenish one's energies as a parent and as an individual

From American Academy of Pediatrics. (2015). *Disciplining your child.* http://www.healthychildren.org/English/family-life/family-dynamics/communication-discipline/pages/Disciplining-Your-Child.aspx.

Children frequently model their behavior after that of people they

love or admire (parents, friends, and other adults). Positive reinforcement (rewards for good behavior) is an effective form of limit setting (i.e., **discipline**), used often by upper-class parents. **Punishment**, a negative reinforcement as reflected in shaming a child in front of the child's community or family (seen with some Asian cultures), may stop an undesired behavior but often only until the child repeats the action and is not caught. Lower-socioeconomic-class parents tend to use more punishment directed toward misbehavior or failure to adhere to parental values and requirements.

Child Abuse

Child abuse (physical, sexual, or emotional exploitation of children) and neglect (lack of adequate food, shelter, or emotional support) continue to be significant societal problems. According to the USDHHS (2011) and the AAP (2011b), more than 3 million cases of abuse or neglect in children are reported annually in the United States. Abused children have an increased likelihood of becoming violent adults and of abusing their own children. The factors that increase the risk of abuse include family poverty, culture, limited maternal education, needy child syndrome, presence of a stepfather, single-parent status, parental drug addiction, and teenage parenthood (AAP, 2011b). However, child abuse also occurs in families that do not have these risk factors. Cultural factors must be considered in detecting abuse. For example, coin rubbing of the chest (used in the Asian ethnic group for treatment of respiratory tract infections) leaves abrasions that may be perceived as abuse by a nurse assessing an ill child. National governmental agencies and professional organizations require that health care providers report suspected abuse and participate in preventing, assessing, and treating victims. State nurse practice acts require nurses to report suspected cases of abuse. Ultimately, nurses help interrupt the vicious cycle of abuse by becoming involved in community coalitions and innovative evidence-based programs that prevent and intervene in child and family abuse.

Unfortunately, relationships between children and adults are not always positive. **Sexual abuse**, use of a child for sexual exploitative

purposes, has become a more common but often hidden problem for a variety of reasons (AAP, 2011b; USDHHS, 2011): the child may be too frightened to talk about the situation, families and society do not want to admit its existence, Internet traffic has supported pornography and pedophilia, and fewer agencies exist to respond to these cases. Many victims know their abusers (many are parents), and people in positions of authority (e.g., teachers, coaches, or clergy members) may be abusers. The child may comply for a variety of reasons, such as a need to be good or a need to keep the family together. Emotions are complex and change as the child grows, but they often lead to adult anxiety, depression, and physical symptoms and illnesses. Males less often report sexual abuse but are more likely than girls to suffer negative emotional effects from incest, a form of sexual abuse.

As in any type of suspected abuse, nurses assist these children by recognizing those at risk and those experiencing abuse and referring them to relevant resources. All people who work with young children must acknowledge the warning signs of abuse (Box 20-7). When sexual abuse is suspected, an in-depth interview and examination must be conducted by a specially trained, multidisciplinary team that is sensitive to the needs of the child and can validate the abuse. Most authorities believe that children who describe sexual abuse are telling the truth because the details are usually specific and trauma is evident. Therefore a child's story should be believed unless it is disproved.

Box 20-7

Warning Signs of Child Abuse

- Physical evidence of abuse or neglect, including previous injuries
- Conflicting stories about the "accident" or injury from the parents or others
- Injury or complaint inconsistent with the child's history or developmental level (e.g., the child received a concussion and

broken arm from falling off a bed)

- Signs and symptoms consistent with signs of abuse and inconsistent with history, vague recall of event (e.g., chief complaint is a cold when there is evidence of first-degree and second-degree burns)
- Inappropriate response of caregiver, such as an exaggerated or absent emotional response, refusal to give consent for additional tests or agree to necessary treatment, excessive delay in seeking treatment, or absence of the parents
- Inappropriate response of child, such as little or no response to pain, fear of being touched, excessive or lack of separation anxiety, or indiscriminate friendliness to strangers
- Child's report of physical or sexual abuse
- Previous reports of abuse in the family
- Repeated visits to emergency facilities with injuries

Sexuality-Reproductive Pattern

The preschool child learns about sex differences and begins to model the general societal behaviors expected of a female or male child. The child enters the school-age years with a strong identification with the parent of the same sex. The child continues to learn the concepts and behavior of the gender role and incorporate these into the self-concept. This challenge is significant for all children, but more so for homosexual children. Societal stereotypes related to gender roles continue to influence the school-age child's ideas of male and female roles. Fortunately, most children receive early teaching about gender roles that emphasizes that sex does not determine one's choices, personality, or behavior. As a result of this teaching, children

increasingly choose occupations based on their skills and interests, rather than on what appears appropriate because of their sex.

The school-age child's increasing awareness of the body, its functioning, and a need for sexual identity combine to foster a desire for knowledge about the biological aspects of sexual function. Late in the school-age period, when the physical changes of puberty have begun, concern and curiosity about sexual issues frequently develop. A child may become extremely attached to another of the same sex, and they may explore one another's sexual organs. This is common exploratory behavior and does not reflect true homosexuality, even though parents and children may express concerns about it. With the advent of physical changes of puberty, the school-age child desires more privacy in a bedroom shared with no one. As noted earlier, the physical changes of puberty appear gradually over several years.

Children frequently share questions about sexual matters with their peer group. Parents are often uncomfortable or unsure of what sexual information to give to their children and when to give it. Many health care agencies sponsor short programs to educate parents and older school-age children, in a supportive environment, about body and mental changes during preadolescence and puberty. An increasing number of age-appropriate books that focus on emotional and body changes can be used at home and in school to increase children's understanding. Particularly because menstrual cycles start earlier now than they did 50 years ago, education about body changes and puberty appears appropriate as part of later school-age education.

The nurse plays an important role in sex education in health care and education settings. This professional should be receptive to answering questions in this area and at each health care visit. The nurse employed in the school is in an ideal position to teach group, sex education programs using literature and games. Children at this age appear to respond most favorably with sex-segregated classes because of their general discomfort with sexual topics and unique needs and questions. Some schools appropriately incorporate these classes into school curricula as part of a health-promotion curriculum. Other schools have special programs focused only on sex education

based on parental desires or school board policies. Most school-age children have the cognitive skills to respond to programs on responsible sexuality, including discussions on abstinence and condom use, pregnancy, sexually transmitted diseases, and the human immunodeficiency virus (Krause-Parello & Samms, 2010). The nurse also wants to include program content specific to disabled children, who face unique body changes and concerns and need to understand ways others can express affection to them without causing accusations of abuse.

Coping–Stress Tolerance Pattern

The school-age child must learn to cope with stress as part of the developmental process. Through a health-promotion program, children can learn to identify symptoms of stress (pounding heart, stomach "butterflies," and sweaty hands) and ways to cope with these perceived stresses (e.g., deep breathing and walking) before they cause illness. The child actually faces many stressful experiences in life, including competition, homework deadlines, failure at home or school, and decisions whether to cheat, steal, or even join an unpopular peer group. The young school-age child may never have shared his or her life with other children the same age, and cultural values learned earlier in life may not be reflected in school or in peer relationships. Threats to the child's security (e.g., **bullying**) cause feelings of helplessness and anxiety that may affect the ability to function successfully (Reuschel, 2011). Grief over the death of a loved one, parental divorce, loss of a favorite activity because of misbehavior, or expulsion from a favorite peer group may cause negative behavior. Parents need to provide appropriate discipline in responding to this behavior but should also listen and analyze factors related to the problem so as to increase the child's feelings of control and decrease stress for the family.

Children use a variety of **coping strategies**, healthy behaviors intended to buffer perceived stressful events. However, in a very stressful situation or many stressful situations, a child may be unable to move beyond the coping behaviors. In conversations with teachers

and parents, the nurse may offer a variety of strategies for coping with a school-age child's problems, enabling the child to cope and learn from others (Table 20-2). These strategies may involve role-playing or referral to literature on the problem topic to interrupt the child's negative behavior cycle and improve family health (see Table 20-2). The nurse may also refer a child to relevant religious and spiritual leaders, on the basis of school-age children's belief that prayer will help them cope with an otherwise uncontrollable situation.

TABLE 20-2

The School-Age Child's Coping Strategies and Nursing Interventions to Promote Coping

Coping Strategies	Nursing Interventions
Use of defense mechanisms (regression, denial, repression, projection, displacement, sublimation) Cognitive mastery (problem-solving, communication)	Accept child's use of defense mechanisms as temporary, healthy coping responses; provide child with options for moving to more age-appropriate ways of responding to stressors Ask children what they know of the situation and how they might handle it; encourage questions; use diagrams and models to help explain; encourage child to verbalize feelings and use past successful strategies that might help deal with present stressors; try personalized approaches, such as books, puppets, and manipulation of equipment, to increase feelings of control when faced with a stressful situation; encourage praying and other communications to a chosen deity as appropriate
Controlling, holding behaviors	Encourage child to participate and to make decisions; accept child's need to direct as appropriate; set consistent age-appropriate limits; respond to signals for help; let child be responsible for self-care
Use of repetition	Use books, games, and other communication media to work through feelings; emphasize "ok" for child to continue to ask questions and to receive answers that assist in coping
Use of humor	Be a good listener and participate in riddles and jokes used by child; be a good sport with school-age children's desire to play jokes on each other; share stories and cartoons with child
Motor activity, aggression, protest behavior	Encourage physical activity to deal with stress; accept appropriate behavior; establish limits on behavior for group safety
Withdrawal (resurgence of separation anxiety)	When child is separated from the family, child may have separation anxiety; encourage close emotional contacts between child and significant others (friends, family, church members); allow favorite objects from home to be brought to the hospital or a new environment for child

Parental Divorce

More than half of all marriages end in divorce, leaving many school-age children to face stress related to their parents' separation. Often children experience a feeling of loss, although they may hope that their parents will reunite at some point. Box 20-8 discusses the effects of divorce on a school-age child. Children's responses vary with their level of development (Kim, 2011). Factors such as economic security; availability of both of their parents, other family, church, and school supports; and quality of interactions with their parents can influence the child's ability to cope with divorce. Unfortunately, many parents become so immersed in their own feelings that they fail to support their children (Pickhardt, 2011). Conflicts over custody, child support, and visitation rights add to the child's difficulty in coping. Sometimes the school system becomes the child's advocate to encourage the parents to provide a supportive environment during divorce proceedings. Despite this intervention, some children do not cope well with the divorce and have emotional consequences that result in juvenile behavior problems or require long-term counseling (see the case study and care plan at the end of this chapter).

Box 20-8

Effects of Divorce on the School-Age Child

School-age children tend to view life in black and white and are likely to blame one parent for the breakup. Boys, especially, mourn the loss of their fathers and frequently express anger at their mothers. Both boys and girls have great difficulty accepting their parents' new dates. Crying, daydreaming, and problems with friends and school are common divorce-related behaviors in children of this age.

Here are some suggestions that might help the school-age child cope with divorce of parents:

- *Discourage reconciliation fantasies.*

Have parents avoid dinners, outings, or holiday celebrations with the ex-spouse. This only fuels the

child's fantasies. Instead, emphasize the finality of divorce.

- *Make sure the child has the phone number of the absent parent.*

Both parents should encourage easy access and frequent conversations with the noncustodial parent.

- *Do not allow the child to manipulate the parents into buying more possessions.*

School-age children are likely to feel deprived. Although they may intensify requests for playthings or other possessions, do not try to retain child's affection through material objects. Even children of divorce need to be told "No!"

- *Talk to the child's teachers or school counselors about the divorce.*

School personnel may better understand possible learning or behavioral problems and will likely offer extra support.

From Pickhardt, C. (2011). *Impact of divorce on young children and adolescents.* http://www.psychologytoday.com/blog/surviving-your-childs-adolescence/201112/the-impact-divorce-young-children-and-adolescents.

Somatization and Depression

Children, like adults, use defense mechanisms to cope, with various degrees of success. Two strategies used by the school-age child to

respond to uncontrollable situations are **somatization** and **depression**.

Some children respond to a stressful situation by transferring their feelings to a physical problem (somatization). In this phenomenon, school-age children, unable to discuss their concerns, complain of stomachaches or headaches, symptoms reflective of functional or psychogenic pain. These children may also develop discrete, repetitive movement habits called tics. In many cases the child with these problems must be evaluated to determine whether an underlying physiological cause exists. The child and the family will then need assistance in understanding the child's concerns to define successful ways to cope with the behavior.

Depression occurs in up to 2% of school-age children (AAP, 2015e), and more often in boys than in girls during the school-age period. Depression reflects a disturbance of mood, when a child displays sadness, guilt, or worthlessness, and other unusual behaviors that disengage the child from peers and the family. In defining depression in children, most authors emphasize that they are referring to a more long-term syndrome in which the child's normal development and functioning become impaired, not a periodic sadness that all children occasionally experience. The factors that place a child at risk of depression include homelessness, death of a parent or significant other, divorce, long-term hospitalization, chronic illness, learning problems, and emotional turmoil at home. Parents and teachers look for symptoms of depression, including anorexia, sleeplessness, lethargy, changed affect, aggressive behavior, frequent crying, and withdrawal from previously enjoyed activities.

Although it has been concluded that there is insufficient evidence to routinely screen all school-age children for depression, the nurse can serve an important role in identifying any child who appears to be depressed and in notifying parents about the need for further assessment. Depending on the child and the situation, differing amounts of counseling and individual child guidance may be required. Nurses in schools and outpatient settings are often the ideal helpers because they have the skills and time needed to help a child cope with a helpless feeling and its cause.

Values-Beliefs Pattern

Children make decisions related to moral and ethical issues every day. Should they tell the teacher which classmate broke the rule? Should they share their candy with a younger sibling? For these situations, the child makes a decision on the basis of the level of **moral development**. Moral development involves choosing the most appropriate behavior on the basis of one's values and feelings related to the situation. Environmental factors and culture strongly influence a child's moral development, as do the type of family discipline, role models, people with whom the child identifies, and the child's rehearsal and practice of moral behavior.

Kohlberg's Theory

Most researchers agree that the younger school-age child is at the **preconventional** level, a level of moral development characterized by self-interest only. The child continues to do many things simply to avoid getting in trouble and does not understand the reason for rules, but also performs actions that will benefit the self (Kohlberg, 1981). During later childhood (10–13 years) most children progress to the conventional level, a stage of moral development defined by concern about group interests and values. The conventional level of moral judgment involves the child looking to others for approval and to societal authority for a definition of rules. Children aged 10 to 12 years judge a behavior in terms of the intention of the offender, understand the "golden rule" concept, and engage in behavior that maintains a valued relationship. The conventional level coincides with Piaget's cognitive level of concrete operations and the child's increased social involvement with people outside the home (Kohlberg, 1981).

Moral Behavior Problems

Some moral behavior problems, such as lying, stealing, or cheating, are common during the school-age years. Cultural, religious, and parental values influence a child's moral development, concept of right and wrong, and consequences of not demonstrating moral

behavior. Preschool and younger school-age children frequently lie as a result of fantasy, exaggerations, or inaccurate understanding. As children mature, they may use the defense mechanism of denial to block upsetting situations and maintain self-esteem. The lie then becomes an unconscious act. Older children often lie because they fear punishment or ridicule. Children may cheat because of a desire to win, do well in competitive society, or “look good” for their peers. Children usually steal when they think they will not be caught and they think that there is no other way to get what they want (McLeod, 2015). Although these actions can be quite upsetting for parents, they are common developmental behaviors. Parents frequently need reassurance that the child is normal and will probably outgrow the behavior with parental assistance. They may need help in developing fair rules for behavior and communicating their expectations for a child's behavior to meet parental and cultural values. Therefore the nurse encourages the parents to warn the child clearly not to steal, lie, or cheat; offer other, more socially acceptable, ways to cope with the stressor causing the behavior; and then apply appropriate punishment congruent with an understanding of the event.

Environmental Processes

Physical Agents

School-age children, similarly to those of all other age groups, face daily exposure to environmental agents and factors that may cause injury, illness, or death. Many of these agents and factors are harmless if appropriately used or if there is minimal exposure. Examples include physical agents such as fires; mechanical agents such as bicycles, skateboards, and cars; biological agents such as bacteria; chemical agents such as asbestos; and radiological agents such as X-rays. Death rates from these agents differ among ethnic groups because of access to health care and environmental issues. For example, Native Americans and Alaska Natives experience higher death rates from motor vehicle accidents, residential fires, and drowning than do other groups. Black Americans have higher death rates for unintentional injury than do other ethnic group members (USDHHS, 2012b).

Accidents

Accidents are the leading cause of death in children older than 1 year in the United States (USDHHS, 2013). Most accidents do not result in death, but many serious ones cause significant morbidity and disability. Because of this effect, the nurse has a significant role in educating parents and school personnel on ways to prevent dangers to school-age children and to become involved in public initiatives to create a safer society for them (Safe Kids, 2013).

The agent, host, and environment must be considered when one is developing solutions to decrease the number of accidents. The type of agent varies with the child's age. Most fatal accidents during the school-age period occur from motor vehicle accidents when the child (host) is a passenger or pedestrian (walking or riding a bike). Other fatal accidents occur from fires and burns, riding bicycles, drowning, and use of firearms. Most common nonfatal accidents tend to be

caused by simple agents that produce simple injuries. Despite helmet laws in several states, many school-age children continue to experience head injuries related to recreational equipment, such as bicycles, swings, skateboards, and trampolines (CDC, 2014b). Slightly older children have an increased number of accidents from contact sports and cuts, falls, and burns, and injuries from firearms.

Specific accident factors relate to the host—the school-age child (Box 20-9: Quality and Safety Scenario). Children in this age group tend to become hurt because of their carefree attitude, curiosity, love of mimicking older people, and intense oral tendencies. Typically, school-age boys have more accidents than school-age girls, perhaps attributable to differences in personalities, societal expectations, childrearing practices, and increased propensity for risk-taking behaviors. The mechanism differs with the sex of the host. For school-age boys, drowning is the most common fatal accident; for girls, automobile accidents are the most common (AAP, 2012; CDC, 2015a; Daly et al., 2010).

Box 20-9

Quality and Safety Scenario

Safety Concerns Specific to School-Age Children

Because of increased independence, school-age children face significant exposure to situations threatening their health. Consequently, the parents of these children must be involved in community and legislative activities that provide safe play environments. Additionally, at appropriate health visits, health care workers should provide anticipatory guidance to parents in the following areas:

Bicycle Safety

Each child should have a well-maintained bicycle, ride only in safe areas approved by the parents, observe rules for vehicle traffic, ride on the side of the road with traffic, "bike defensively," and use a

federally approved riding helmet.

Street Safety

Children should look right, left, then right again to check the safety of crossing a street; children should cross only at safe and well-monitored intersections, preferably with an adult present; ensure parental supervision when children play close to streets and heavy traffic areas.

Motor Vehicle Safety

Children should wear a seat belt or be in an age-appropriate booster seat as needed; older children should ride with a restraint system and in the back seat until age 12 years.

Pool Safety

All children should have swimming lessons and swim with a buddy or adult who swims well; all pools should have drain covers; children should avoid swimming after a heavy meal and avoid "roughhousing" behavior around the pool; children should be monitored by the parents during swimming.

Firearm Safety

Adults need to lock away guns and ensure gun safety locks are intact; parents need to educate children *never* to touch guns.

Playground Safety

All playground equipment should meet federally approved standards; children should be trained on how to use equipment safely; equipment should be evaluated for safety and repaired before children use it.

Fire Safety

Working smoke detectors should be in place in the home and school; the family needs to have a fire evacuation plan and practice it; children need to wear fire-retardant clothing at night; children should

not play with matches, open fires, fireworks, or open wires that can cause injury and fire.

Toxin Safety

Children should avoid insecticides, radiation sources, inappropriate use of medications, and pollution sources; parents need to store all known toxins, chemicals, and household cleaning agents in an adequately ventilated location that is inaccessible to children.

Stranger Safety

Children should play with friends, have a plan for returning home, know the home phone number and address, play in a safe and known area, and report any suspicious activity threatening their safety to an appropriate adult; children should know how to say “no” and how to locate assistance when in an unsafe situation.

Sports Safety

Children need to engage in age-appropriate activities and wear protective equipment relevant to the sport; parents need to ensure safety and maintenance of all sports equipment; parents need to caution children against hazardous sports, such as tramlining.

Animal Safety

Parents should teach children to avoid strange animals, especially sick or injured ones, and ensure that personal pets receive vaccinations; parents need to teach children not to mistreat pets and not to place their faces close to any animal.

Although nurses offer suggestions to parents to improve their children's play safety, studies have shown that few parents follow these suggestions. The reasons for this behavior include parental difficulty in assessing the safety of and age-appropriateness of play equipment, the amount of effort involved, and a lack of money to create a safe play area. The nurse helps parents respond to these perceived barriers. With more children using skateboards and rollerblades, the nurse also encourages the use of child safety helmets

and knee, elbow, and wrist guards to prevent muscle sprains and bone fractures. The school offers an on-site opportunity for teaching children, teachers, and parents about accident prevention. In addition to providing this guidance, nurses can participate in legislative and educational actions to increase community consciousness about child safety.

The physical environment of the child dictates the type or frequency of accidents, which occur in the home, neighborhood, and school. Most accidents happen outdoors, which means that school-age children face greater risk of automobile or bicycle accidents than of poisoning or falls, indoor accidents that occur predominantly in younger children. More accidents (drowning and pedestrian-vehicle accidents) occur in the summer than in the winter because of children's outside play. Socioeconomic level affects children's physical environments and access to dangers. For example, space heaters place children of low-income families at risk of burns, whereas skiing places wealthier children at risk of injury.

The social environment, which includes the family, school, and playmates, also plays a role in accidents. Although little research has focused on the physical trauma caused by heavy backpacks that many school-age children use, these bags exert significant pressure against functionally immature muscles of the back and torso. Daily carrying of bulging backpacks causes muscle strain, headaches, improper posture, shoulder slouch, and other physical problems. Additionally, teachers' expectations that all textbooks be available both in the classroom and at home must be considered. At least one study has shown that children will change their backpack-carrying behaviors if they are involved in a school-based program focused on this topic (AAP, 2012).

As part of the social environment, the family may influence the rate of accidents in the school-age child. Chronic familial stress (parental unemployment) or sudden acute stress (parental illness) may contribute to homicide as the third leading cause of death among children aged 5 to 14 years (USDHHS, 2013). Homicide is a more

common cause of death among black American and Hispanic children than among white children. Children also face increased risk of accidents when parental supervision is limited, such as during holidays or a move to a new home.

Drowning

Fewer school-age children than infants and adolescents die of drowning. More black American children of this age drown than do white American children (CDC, 2014e). Water safety measures can help reduce drowning, along with the many other injuries that occur around water, such as falls in slippery areas. Environment and safety teaching can influence the number of school-age children dying of drowning.

Burns

Each year many children become victims of house fires, many of which occur during the winter months from Christmas trees, space heaters, and fireplace malfunctions. Many homes lack working smoke detectors because of incorrect installation or inadequate testing. If a fire occurs in a home with a smoke detector, the risk of death is decreased by 40% to 50% (CDC, 2012). Most burned children survive, frequently with various degrees of physical and psychological scars. Children need to learn about fire safety, including the importance of avoiding situations involving fire and practicing fire drills routinely at school and home. The nurse encourages parents to understand other practices to prevent fire-related problems, including parental purchase of flame-retardant sleepwear for children.

Firearms

People in the United States who use firearms frequently cause fatal injury through homicide, suicide, or accidents. Every 2 hours 45 minutes someone's child dies from a gun accident (USDHHS, 2013). With many US homes containing a handgun and because of recent

shootings by adolescents, concern about children's safety remains well-founded. Possibly the best means of preventing accidents with firearms is to ban them from private ownership, as seen in England. However, because handgun ownership is an important individual right in the United States, several states have passed legislation that allows handguns for individual protection. Families with firearms in the home should store them in a locked area apart from ammunition and consider using nonlethal (wax) bullets. All family members should be knowledgeable about gun safety.

Much debate has been raised recently regarding the use of toy guns by children. Unlike video game use, the use of toy guns during childhood does not increase the likelihood of violent or aggressive behavior later in life. Unfortunately, there have been a number of deaths associated with police mistaking a toy gun being used by school-age children for a firearm. These deaths have occurred in spite of mandatory markings on toy handguns.

Sports and Recreation

Accidents from sports and other recreational activities increase during the school-age years and include lacerations, contusions, hematomas, concussions, sprains, and fractures. Some evidence exists that adolescents now have more musculoskeletal injuries because of involvement in repetitive team sports earlier in their lives. This suggests that society needs to examine the current emphasis on initiating young children with musculoskeletal immaturity into team sports such as football, hockey, soccer, and basketball. Intense social pressure for children to participate in these sports means that parents and school systems must ensure that each child has protective body devices to prevent injuries, as well as psychological support to allow a child to benefit from the team sport. There is a further need to increase safety by ensuring that each child fits the sport, has adequate hydration during the game, and engages in conditioning exercises before and after the game for prevention of injuries. Furthermore, the literature supports societal need to focus more on the collaborative skills children learn by being part of a team, rather than the intense

focus on winning philosophy found in many school-age team sports.

Recreation area injuries may be prevented by several measures. The National Bureau of Standards set guidelines in 1976 for home playground equipment, regulating objects such as sharp edges, moving parts, and equipment design. Nurses help prevent accidents by participating in decisions about school playground equipment and counseling families on a variety of issues. Playground safety has become an important issue because 200,000 children need emergency department assessment each year for related injuries (USDHHS, 2013). Girls are slightly more likely to be injured on the playground than boys, and many of these injuries occur in low-income neighborhoods where playgrounds fail to meet safety standards (CDC, 2012).

Mechanical Forces

Motor vehicles and bicycles are the two most common mechanical agents that cause injury to school-age children.

Motor vehicles.

The leading cause of death in the United States in all individuals from age 1 year to age 34 years is motor vehicle accidents (CDC, 2015a). Children die as passengers in cars, as pedestrians, and as bicycle riders. In the United States, more children die from pedestrian-related accidents than from passenger-related accidents (CDC, 2014b). Since 1999, 127 children have died each year in bicycle accidents, 80% of whom did not wear helmets to prevent head injury. Helmet use in children can reduce the risk of head injury by 45% (USDHHS, 2012b). Although not all accidents result in death, children may also sustain injury that causes permanent disability as a result of motor vehicle accidents.

Automobile passenger injuries can be prevented, or the severity reduced, by alteration of some aspects of the child's environment. Lower speed limits, stricter enforcement of alcohol-related laws, better automobile and highway designs, improved door lock mechanisms, and more effective restraint system requirements in all states have reduced the severity and number of accidents and injuries (USDHHS,

2012b). However, more injuries have been correlated to higher speed limits instituted in the United States several years ago. Furthermore, many children remain at risk of injury because various school districts and states do not require seat belts in buses used to transport students, despite a recommendation by the AAP to do so.

Proper and consistent use of federally approved belt-positioned booster seats for children aged 4 to 7 years decreases the likelihood of child death and serious injury significantly (AAP, 2015a). However, one study showed that only 19% of such children used these seats. Less than 10% of children needing the protection of a booster seat ride in one, and younger, smaller school-age children (shorter than 4 feet 9 inches) often fail to use them correctly (Governors Highway Safety Association, 2015). The reasons given by parents and children for their not using seat belts or booster seats include forgetting to use the device, having difficulty reaching and fastening belts, feeling discomfort from wearing the belt or using the seat, and receiving misinformation about the need for the belt or seat for short trips. Clearly, consistent use of booster seats by young children and seat belts by older children and adults, who model seat belt behavior to their children, will occur only when legal enforcement occurs. Federal government and national professional groups recommend that all children younger than 12 years ride in the automobile's back seat in an appropriate restraint because of the potential for death from an air bag activated in a motor vehicle accident (Daly et al., 2010; Governors Highway Safety Association, 2015). Many families have difficulty meeting this recommendation because of long-term acceptance of older children riding in the front seat after they have outgrown booster seats.

Urban children younger than 15 years old experience more than half of all pedestrian-automobile accidents. These occur when they are using rollerblades, skateboards, and skate scooters and tend to be more severe (head injuries) than passenger injuries. Many factors cause pedestrian accidents: children often have difficulty interpreting traffic signs and judging the speed of cars, and they forget to look carefully before crossing the street. Although overcrowding, poverty,

high volume of traffic, stress, and unsafe play areas influence children's street safety, various principles can direct interventions to decrease the number of street dangers.

Bicycles and motorized vehicles.

Many accidents occur each year with young children on bicycles, motorized skateboards, and all-terrain vehicles (ATVs). Most of these are not serious, but deaths occur among young children who have suffered head trauma or significant body injury from inappropriate use of this equipment. The AAP (2012) recommends that only people at least 16 years old ride ATVs and then only in rural areas with adult supervision. Bicycle accidents occur most frequently near the child's home and during the day, and commonly involve injuries from the spokes when children ride behind the bike seat. More boys than girls experience these injuries from bicycles, motorized skateboards, and ATVs, perhaps because of their greater risk-taking behavior (Daly et al., 2010).

In response to children's developmental behavior related to bicycles, motorized skateboards, and ATVs, the nurse addresses safety issues. Additionally, nurses encourage parents to teach and reinforce safe bicycling habits to their children and should sponsor helmet and bike programs within the school (Box 20-10).

Box 20-10

Nursing Interventions to Prevent Accidents During the School-Age Period

Strategies for Counseling

- Discuss accident prevention at optimal times, such as during prenatal visits or well-child visits, after the arrival of a new sibling, or after an accident.
- Rather than discussing all topics at once, pick the main concerns for the developmental level of the child at each well-child visit. For the

school-age child, these topics include motor vehicle, water, fire, and bicycle safety.

- Repeat information at other visits to emphasize its importance.

Community Actions

- Use supplemental materials, such as pamphlets, to reinforce the verbal information.
- Support local and national legislation that sets standards for potentially harmful agents. Mandating standards has been one of the most successful accident preventive strategies, as seen in the Poison Prevention Packaging Act and the Flammable Fabrics Act.
- Encourage children to wear a bicycle helmet and other protective gear when appropriate. Many nurses have been active in lobbying for bicycle helmet requirements in their states.
- Consult with manufacturers on safe designs of materials used by children.
- Report objects that are potentially hazardous.
- Participate in local activities that stress accident prevention, such as those organized by local offices of the National Safety Council.
- Educate groups, such as schoolchildren and parent organizations.

From US Department of Health and Human Services (2012). *An agenda to prevent injuries and promote the safety of children and adolescents in the United States.* http://www.cdc.gov/safechild/pdf/National_Action_Plan_for_Child_Injury_Prevention.pdf

Biological Agents

School-age children face constant exposure to bacterial, viral, and other biological agents that pose threats to or improve their overall health (e.g., immunizations). Compared with the preschool child, the

school-age child has fewer illnesses. The most frequent illness continues to be upper respiratory tract infections (URIs), illnesses shared among schoolchildren who fail to practice good handwashing techniques and avoidance of ill peers. These illnesses cause children to lose school days and learning opportunities. Most URIs result from viruses, but bacteria can play either a primary or a secondary role. Two problems associated with URIs are streptococcal infection ("strep throat") and otitis media.

Strep throat occurs frequently among school-age children. A child with an infection from group A *Streptococcus* may have a severe sore throat, fever, and malaise, or may have only a minor sore throat. A throat culture confirms the diagnosis, and antibiotic treatment typically cures the infection. Children are noninfectious after 24 hours of treatment and may return to school (Wald, 2015). If not treated, the affected child may develop rheumatic fever or acute glomerulonephritis as a secondary infection following the sore throat. Greater transmission of streptococcal infection occurs in areas where there is close personal contact during colder weather. The school nurse's preventive efforts focus on teaching the children good handwashing techniques and identifying children who complain of sore throats. Children with throat infections caused by other strains of *Streptococcus,* such as group B, do not usually require treatment, because these infections generally do not cause the same serious complications.

Otitis media rates have subsided with the integration of the pneumococcal and influenza vaccines into the immunization schedule. Acute otitis media is often self-limiting and can often be regarded as a complication of a preceding or concomitant upper respiratory tract infection. Most cases of otitis media will resolve spontaneously. Without specific treatment, symptoms abate within 24 hours in 60% of children and settle within 3 days in 80% of children (Toll & Nunez, 2012). The nurse is in an integral position to help support the family and educate the family on risk factors associated with otitis media and nonpharmacological therapies that may alleviate symptoms and discomfort during the course of illness.

The school-age child may experience other illnesses. The frequency of gastrointestinal tract infection (**gastroenteritis**) decreases during the school-age years but is still the second most common acute condition of childhood. Usually caused by a virus, gastrointestinal tract infections cause vomiting and diarrhea. Older and larger school-age children have little chance of rapid dehydration; they basically react to the illness the same as do adults and need to be treated similarly. Gastroenteritis is contagious, and therefore the nurse should monitor schoolchildren for symptoms of illness and encourage proper handwashing to prevent transmission of the virus from one child to another.

Scabies and **pediculosis** are common skin disorders among school-age children, involving extreme itchiness of either the body (scabies) or the head (pediculosis), and are easily spread to other children (Gupta, 2015). The nurse educates parents to visualize the mites and **lice** or use a lice comb to check their children for mites and lice when they complain of itchiness or seem to be constantly scratching their heads. Previously, children with lice could not come to school until they were lice-free, which isolated students from their peers and influenced state school funding based on student attendance. The AAP now recommends that once children are undergoing treatment for the problem, they should be allowed in school (Devore & Schultz, 2015a).

Most states require that the child's immunizations be current before the child enters kindergarten or the first grade and that additional tetanus immunization be given every 10 years or when an unclean wound is acquired. Other immunizations recommended by the AAP include a **meningococcal vaccination** at age 11 or 12 years and the series of three injections for hepatitis B and **human papilloma virus** during the late school-age and early adolescent years (USDHHS, 2012b). If the child has no history of chickenpox, a varicella immunization is also recommended. In many states the school nurse has a responsibility to ensure that all students' immunizations are current, and if they are not current, the nurse informs the parents that the children may not attend school until their immunizations are up-

to-date (CDC, 2015f; USDHHS, 2012b). Any child lacking age-appropriate immunizations can "catch up" according to a schedule developed by the AAP. Although 79% of American children receive immunizations by school entrance time, increasing numbers of immigrants and transient workers have deepened concern about exposure of Americans to previously conquered diseases (e.g., tuberculosis). Strides toward meeting the *Healthy People* initiative targets related to immunizations continue to be made according to the midcourse review and the 2020 objectives (CDC, 2015f; USDHHS, 2012b).

Chemical Agents

A number of potentially toxic chemical agents exist in the environment, and the child is exposed to these through inhalation, ingestion, or direct contact. Children are particularly susceptible to chemical hazards. Food and drugs are two sources of chemicals ingested by children on a regular basis, and some older school-age children ingest tobacco as a result of cigarette smoking. Although normally safe, some foods and drugs can be harmful when used inappropriately. Other environmental hazards include pollution, heavy metals (lead and mercury), and pesticides.

The nutritional needs of the school-age child were discussed earlier in this chapter. As stated, children frequently eat foods with large quantities of sugar, salt, and fat and with chemical additives. The effects of some of these additives have been questioned, and concern has been expressed about the effect of biochemically altered food on children and future generations. On a short-term basis, some foods may cause allergic reactions; on a long-term basis, some may contribute to the development of coronary disease, hypertension, and cancer. Nurses are aware that the child's diet may contribute to future health problems, and therefore assess intake and counsel the child and parents accordingly about ways to improve it.

The incidence of poisoning decreases during the school-age years as children become more aware of the appropriate uses of drugs and other agents. Childproof containers have decreased exposure of

children to dangerous poisons and chemicals in the home. However, children continue to face exposure to drugs (alcohol and glue inhalants) because of less monitoring by working parents, and older school-age children face exposure to recreational drugs, primarily through their peers and older children. In the school environment, the nurse and school personnel need to encourage students to engage in wise decision-making about recreational drug use that will affect their future and overall health.

With pressure on older school-age children to smoke cigarettes, attention must be paid to effective strategies to prevent this behavior. Every day, more than 6000 school students try to smoke a cigarette (Tobacco-Free Kids, 2015). Most students who smoke initiate their habit at approximately 11 years of age (AHA, 2014a). White American students start smoking at a younger age than black American students. Males tend to begin smoking earlier than females; however, girls catch up in smoking rates during the middle school years (Tobacco-Free Kids, 2015). The Federal Tobacco Settlement Project provides funds to address the public health problem posed by tobacco smoke in the United States. Although funding for tobacco prevention and cessation programs has reached its highest level in 6 years, many states continue to fall short of the minimal recommendations by the CDC (Tobacco Free Kids, 2015). Attention to smoking as part of a health-promotion program seems merited because so many children begin smoking at a young age; in addition, because nicotine is highly addictive, many believe that this habit leads people to experiment with riskier drugs (cocaine and methamphetamines).

School policies have been instrumental in supporting a tobacco-free environment (Adams et al., 2009). By 2014, 74% of schools had prohibited all tobacco use in all locations (CDC, 2014d). To further assist in health-promotion efforts, many institutions require staff development and education programs related to the effects of tobacco use on health. As of 2014, elementary school students require 3 hours of instruction on tobacco use prevention (CDC, 2014c). There have been various governmental efforts to reduce exposure to environmental tobacco. For example, 40 states and numerous cities

nationwide have enacted smoke-free laws (American Nonsmokers' Rights Foundation, 2015).

Pollution has become a fact of life for many Americans and, particularly, for the 25% of urban-dwelling children who must breathe air that exceeds federal government acceptable levels for ozone (Breysse et al., 2010). Air pollution irritates the eyes and the respiratory tract, causing URIs, ear infections, and allergies. More children now experience **asthma**, and many inner-city children face higher rates of this disease because of poor air quality, including secondary and tertiary smoke. Knowing the negative effects of air pollution and smoking on their health, many school-age children participate in school projects to improve their environmental health.

Children also face exposure to various toxic materials in their environment. Progress has been made in the past decades to reduce children's exposure to chemical hazards. Lead, for example, has been removed from gasoline and paint. This in turn has resulted in significant reductions in children's blood lead levels. Lead exposure continues to exist. Children are exposed to lead through parents' clothes, shoes contacting lead-infused soil, lead in older residential water pipes, traditional medications in some cultures, and in school building structures. Children living in poverty receive high exposure from lead-based paint used on older and less expensive homes. The long-term effects of lead on children remain unclear, but some evidence indicates children suffer neurotoxic effects from this type of exposure. High lead levels in children contribute to dental caries and hearing loss.

Routine use of chemicals to control insects and undesirable weeds in landscaping has led to increasing concerns about children's exposure to these agents. With increased interest in more natural substances to control insects and gardening problems, perhaps less reliance will be placed on chemicals for these problems in the future. Knowing the primary source of exposure to the most hazardous materials and avoiding these materials are often sufficient to accomplish real risk reduction and offer substantial protection within the child's environment (World Health Organization, 2015b). Various

behaviors can be implemented to create a safe environment and minimize health risks associated with hazardous chemical exposure. Nurses are instrumental in the assistance and support of parents, schools, and community agencies in the implementation of these behaviors, such as the use of nonhazardous cleaners and pesticide-free foods, and further monitoring of the environment for hazardous materials.

X-ray Exposure

The child receives exposure from both naturally occurring radiation and human-made ionizing radiation. Exposure occurs in various degrees with radiographic examinations of teeth and bone, from nuclear power plants and explosions, and in the management of many childhood cancers. Children exposed to high levels of radiation risk developing breast or thyroid cancer or leukemia and compromised growth. With little advocacy in this area, nurses and other professionals improve children's health by becoming active in initiatives that focus on prevention of chemical and radiation hazards.

Cancer

Leukemia is the most common form of childhood cancer. Of those younger than 5 years affected, 90% will be cured with current medical treatment. Among the 12 major types of childhood cancers, leukemia and cancers of the brain and central nervous system (second most common forms of childhood cancers) account for more than 50% of all new cases (National Cancer Institute, 2015). Lymphomas (Hodgkin disease and non-Hodgkin lymphoma) also affect school-age children and adolescents as the third most common group of malignancies. Non-Hodgkin lymphoma is more common during the school-age years, and boys experience this malignancy three times more often than do girls. Mortality rates in the United States tend to be greater in densely populated areas, particularly where the more educated and wealthy live. The most common symptom is abdominal pain caused by intestinal obstruction or organ compression. With effective

treatment regimens, children with limited disease may be cured but may experience side effects of treatment later in life (e.g., development of cataracts, dental problems, learning difficulties). Advances are being made with the use of genomic sequencing and the use of genomic medicine to explore novel treatments with the goal of improving childhood cancer outcomes (Downing et al., 2012). Children with cancer present a challenge to the nurse because they are in various stages of recovery, may be developmentally delayed as a result of prolonged periods of absence from peer groups during therapy, and may fear a recurrence of their disease. The nurse provides psychological and emotional support to affected children and their families to help children develop peer relationships and meet developmental goals important to them during the school-age years.

Determinants of Health

The school-age child interacts daily with other children and adults to become more independent by age 12 years. Mutual problem-solving by the child and the parents or friends frequently occurs at this age related to a higher level of maturity in social relationships and concerns. Exposure to a variety of social roles and expectations of others strengthens the process of socialization so that the child develops social competence—the ability and skills to participate effectively in the social interactions of society. Social competence includes both the obvious social behaviors and an inner understanding of the appropriateness of behaviors.

Several elements play a role in the development of the child's social competence. The child's desire for a sense of industry encourages interactions, positive relationships, and accomplishments within society. Cognitive development supports understanding of relationships and effective problem-solving. Moral judgment helps the child understand consequences and fairness in relationships. Understanding and obeying authority help to maintain order in society. Social sensitivity is a result of social interactions and requires the child's ability to perceive the social cues of others, understand the roles of others, and communicate verbally with them. Social behaviors are also a part of social competence; these are learned most frequently through imitation, role-modeling, and reinforcement of others' behaviors. The interaction of all these elements produces a level of social competence and simultaneously plays a role in the child's self-perception. Individuals frequently see themselves as others see them.

Social Factors and Environment

Peers

The strongest relationships that school-age children develop outside their families are with their peers (other children encountered in the neighborhood and school). The peer group acts as a new social

system, becoming increasingly influential in the child's life. All children continue to be influenced significantly by the family, the culture of the family, and many other environmental factors, but the peer group begins to influence lifestyle, habits, and speech patterns and formulate standards of behavior and performance. The standards of the peer group become vitally important, and children attempt to conform to its rules. Being accepted by the peer group becomes more important than being accepted by anyone else (Ferrer & Fugate, 2014). Conforming to the pressures of peers becomes an issue, especially when it interferes with the parents' expectations. When children realize that their own goals, desires, and aspirations might be quite different from those held by the peer group or the school, they must find ways to cope and perform according to the new standards if they are to succeed. The degree to which children fit in socially, learn to cope, and receive satisfaction from the group is a powerful determinant of healthy socialization.

A child may have one best friend or several important friends and a mutual understanding and willingness to help each other. Friendship groups that form during this age may change and become goal directed, such as groups composing a sports team. These groups frequently have set rules or rituals that connect the members. During the middle school years, friendships often revolve around same-sex relationships, videos, songs, books, and media shared by the group. Later in the school-age years, the development of sexual relationships with the members of the opposite sex occurs during dating and mixed parties.

School-age children also become increasingly involved with adults outside the family, including teachers, coaches, and others who become role models, all of whom influence the child's view of the world and self. Although this influence may not be as significant as that of a child's peers, long-term ideas and beliefs frequently develop from these relationships. Children usually perceive some similarity between themselves and their models, those of the same sex with similar physical or behavior traits. During these years, children may not maintain a strong identification with the parent of the same sex,

but they tend to adopt other adult models with whom they can identify.

Working Parents

Both dual-career couples and single-parent families influence their children's safety when no adult is present to monitor the environment after school. Many **latchkey children** who are left alone until their parents return from work follow directions given by their parents. These directions may include beginning dinner in anticipation of their parents' return or completing homework while remaining inside the home with the doors locked.

Parents and school-age children often disagree about how old is "old enough" to be left at home alone or with an older sibling. Although the school-age child might consider being at home alone to be a real mark of maturity, children who look after themselves after school can become more isolated and miss peer relationships important to their development. Nurses give guidance to families who must cope with the issue of after-school care for school-age children to ensure that relevant and safe decisions are made.

Culture and Ethnicity

School-age children focus more on the influences of their culture on their lives than do younger children. Aspects of American culture that the child must confront include poverty and affluence, ethnic and racial differences, acceptance of these differences, and the power of media as a cultural phenomenon in American society.

Ethnic Groups

Preschool children may notice racial and ethnic differences, but school-age children increasingly show evidence of being aware of these differences. This is a time during which attitudes toward race develop on the basis of family and community attitudes. Studies of children aged 5 to 7 years show that most identify with and prefer to

play with members of their own race. As children get older, they may continue this behavior. Although prejudice exists among some school-age children, they may be encouraged to view people from different cultures and ethnic backgrounds in a positive light. Many schools appropriately focus on the importance of other cultures by having multicultural awareness weeks. During these times, children dress, eat, and live as other cultures do, allowing them to recognize the uniqueness of individual cultural beliefs and values (Box 20-11: Diversity Awareness).

Box 20-11

Diversity Awareness

Expectations for Child Behavior Related to Culture

American Indian

Expect the child to respect elders and take pride in heritage; develop natural talents as the child matures; personal independence must balance with accountability to the family, community, and tribe; help sought from family members, not outsiders.

Mexican American

Family environment protects the child; the child is expected to be obedient, respectful, and work hard to reach goals; "next" generation is expected to do better than current generation.

Filipino

Family raises the child in a protective environment; expect the child to conform to the values of the culture, and the child shamed if he/she fails to meet expected behaviors; the child is taught to avoid direct confrontation and hide emotions and to be respectful and shy; strong emphasis on education for personal and financial gain.

Black American

Children are expected to complete family chores and focus on schooling. Respectful behavior toward adults and elders is expected. Discipline is described as less permissive than for European-decent children.

Chinese Americans

The child is highly valued, particularly a male child; the child is expected to honor elders and family needs; high value of education to honor the family and the child.

Television and Video and Computer Games

Television and video and computer games exert a major influence on ideas and behavior in American culture. Unfortunately, many television programs and video and computer games pose harm to children because of their messages and because such activities prevent children from engaging in physical activity. Advances in gaming offer an option for increased activity during gaming activities. Video games and gaming systems have been developed that encourage movement during gaming. Energy expenditure more than doubled when sedentary screen times were converted to active screen time.

Computers connected to the Internet pose a danger unless locking devices have been installed to prevent school-age children from accessing inappropriate websites. Additional concerns have focused on the violent themes of programming, persuasive television commercials, unrealistic depiction of the world, unhealthy food intake, and the passivity of television viewing.

Many times, certain ethnic or racial groups implement the violence in these media sources, leading children to stereotype these groups as the perpetrators of violence. Television facilitates negative attitudes and values among children, increases their aggressive behavior, decreases their emotional sensitivity when aggressive acts occur, and leads them to accept aggressive acts (Adams, 2014). One positive note is that adults who discuss violence with children by pointing out that these acts are unacceptable and cause pain to others can help inhibit some childhood aggression. Discussion of recent acts of violence

committed by young people in such a context also helps. Anger control programs, as part of school health-promotion programs, also help decrease societal violence and produce more collaborative workers needed for the future.

The average child views an overwhelming number of television commercials by age 18 years, and these commercials influence daily and future choices and behaviors. Many television commercials focus on sugary foods that cause damage to teeth, diminish overall healthy habits, and lead to increased rates of obesity. Young children cannot always separate the program from the commercials and believe that they must purchase products the television says to buy. Many childhood authorities question the ethics of exposing children to any type of advertising. Although concern about the effect of advertising has led to programming changes during children's watching time, more work is needed to send more socially responsible messages.

The world as presented on many television shows does not accurately reflect the real world. Despite an increasingly diverse and aging population, stereotypes of women and minority groups and a predominance of younger actors continue to make money for the media industry. Parents and health care providers should monitor television viewing to ensure the age appropriateness of the material, respond to television stations about inaccuracies in the content, and write letters to their newspaper or television networks to express concerns about the material presented. Parents may also participate with their children in responding to media presentations on learning and moral themes. Parents should follow recommendations from the AAP—limit television and media viewing to 2 hours per day, have media-free bedrooms, disallow television viewing while eating, and participate in national "Turn Off the Television Week."

Some positive aspects of television viewing exist. A number of children's programs, such as "Sesame Street," "Wishbone," and "Kratt's Creatures" for younger children and "Bill Nye, the Science Guy," "Cyberchase," and "Zoom" for older children, have been deemed developmentally appropriate for children (Public Broadcast Station, 2017). Likewise, there are excellent websites for school-age

children that stimulate their learning and promote their health.

Increasingly, parents engage their school-age children in learning and playing on a home computer. Although this technology serves as a good resource for locating information, writing papers, and organizing information, parents must limit the time students spend on computers. Likewise, limitations must be put on use of computer games that detract from socialization with peers and the family and take time away from school work.

Levels of Policy Making and Health

Throughout this chapter, laws that support the health and well-being of the school-age child have been discussed. These laws include guidelines for the safe use of products, use of flame-retardant clothes, mandates against tobacco advertisements, and nutritional guidelines for federally supported school lunch programs. Another important law is mandatory public education for disabled children. The Individuals with Disabilities Education Act, formally known as **Public Law 94-142 (Education for All Handicapped Children Act)**, established in 1977, states that any child with special needs (disabled) aged 5 to 21 years has the right to free appropriate public education in the least restrictive environment and evaluation by school or health professionals to identify learning needs. Disability includes having a limitation in one or more functional areas (US Department of Education, 2010) and affects as many as 10% of children aged 5 to 17 years.

Many states begin educational services for affected children at 3 years of age based on an **individualized educational plan** (IEP) for that child and as mandated by law. The school nurse is responsible for collaborating with other school personnel and parents in ensuring that the IEP, including the health care needs of the child and connection to resources addressing the unique learning needs, receives attention. However, some parents have expressed concern that their "normal" or "gifted" child receives less attention in school systems because of the cost and time expenditures associated with implementing IEPs for disabled children. To add further concern, with recent school

budgetary shortfalls, people who have received less training than the school nurse often have responsibility for implementing IEPs. Despite these concerns, the value of Public Law 94-142 has been that disabled people have had their problems addressed in the educational arena.

To ensure access to educational opportunities for every individual, the US Department of Education was developed in 1980. Through the US Department of Education, President George W. Bush enacted the **No Child Left Behind Act of 2001**, aimed at improving the academic achievement of the disadvantaged (US Department of Education, 2010). The No Child Left Behind Act of 2001 intended to help ensure that all children have the opportunity to obtain a high-quality education and reach proficiency on challenging state academic standards and assessments. As a result of the No Child Left Behind Act of 2001, more reading progress was made by 9-year-olds in 5 years than in the previous 28 years combined. Reading and math scores of 9-year-olds and fourth graders have reached all-time highs, and 46 states improved or held steady in all categories of students tested in reading and math (US Department of Education, 2010).

Poverty

In the United States, more than 22% of children younger than 18 years live in families whose incomes are below the poverty level (National Center for Education Statistics, 2015). Among diverse population groups, 50% of black American, 30% of Hispanic, and an unknown percentage of Native American children live in poor economic conditions that negatively influence their health. These conditions include unemployment, inadequate or crowded housing, poor sanitation, poor nutrition, low educational levels, and limited or sporadic access to health and social services perhaps attributable to lack of health insurance or contextual factors of these people's lives. The number of uninsured children continues to be high and limits the number of children and families receiving primary health care. The lack of primary care among black American, Hispanic, and white American children in rural areas prevents needed asthma management, dictating an expanded role for health care providers to

connect families to resources for more effective disease control.

Many homeless children face poor living conditions and high rates of depression related to few friends and poor health status. Migrant children face more disease (e.g., tuberculosis, scabies, and ear infections), injury, and dental caries, and pose treatment challenges because of their transient status. The effects of limited financial resources on children include higher mortality rates at all ages than in those who are not poor or migrant and more school days lost because of illnesses. Numerous problems exist for children in poverty, including greater developmental delay as a result of poor nutrition; increased peer rejection; poorer self-concept; increased risk of accidents, drug abuse, and abuse or neglect by parents; and greater overall poor coping abilities.

Nurses interacting with poor families and their children are familiar with federal health resources, such as the **State Children's Health Insurance Program (SCHIP)**. This program, part of the Balanced Budget Act of 1997 and implemented at the state level, supports comprehensive care for newborns to young adults 18 years of age who do not meet Medicaid criteria but live in families too poor to afford private insurance. This program has advanced children's health by improving access for many groups (SCHIP Information Center, 2010). The nurse improves the overall health of poor children by encouraging relationships with appropriate role models and by reinforcing strong family relationships that help children develop resilient and positive self-images.

Family wealth may have a negative influence on the school-age child if there is frequent substitute caregiving of varying quality attributable to parental absence, extremely high or unreasonable parental expectations, availability of material possessions but little child awareness of relevant responsibilities, and easy access to drugs and alcohol and similar dangers. The nurse reinforces the need in wealthy families for consistent demonstration of parental love and support, firm limits on appropriate behavior, and the value of recognizing the child's unique abilities. The nurse also offers ideas that will help decrease risk-taking behavior (e.g., use of drugs) and

increase parent-child connection until a parent is in the home.

When discussing children raised in poverty or affluence, the nurse remembers at least two points. First, many variables affect each child, often in different ways, to influence overall development. Second, although personality and support networks help a child in a socially poor environment to excel later in life, most authorities believe that problems of affluence are easier to overcome than are the all-pervasive problems of poverty.

Health Services/Delivery System

Well-Child Care

The AAP recommends that at least every 2 years children 6 years or older have a well-child examination by either a physician or a nurse practitioner. In the ideal situation, the child has a primary health care provider, one person or practice from which the child receives wellness and illness care coordinated by members of a health care team. Unfortunately, many American children still do not have this quality of care (see the Poverty section earlier). With increasing numbers living in poverty because of family violence, single parenthood, and divorce, many lack a primary care provider for their physical and emotional needs often because of a lack of health insurance. In this situation, they often receive emergency care only when they are very ill or injured.

The nurse encourages the school-age child and the parents to be active members of any health evaluation. Children may give some of their own history, answer questions, and discuss their health concerns. During the history, the child's privacy should be respected. Some children in this age group want a parent present during the examination; others do not. When possible, the nurse spends at least some time alone with the child to allow discussions that the child may not feel comfortable with when the parents are present. The examinations can also be a time for education on how the body works and ways to keep it healthy. Preventive information on diet and exercise can be offered relevant to prevention of obesity,

cardiovascular disease, and diabetes. Information can also be obtained on school adjustment and performance, particularly because this is a major portion of the child's life. School performance can reflect the child's cognitive and general development. If there are any concerns, the nurse obtains more information through separate testing or discussion with school officials. Health education is directed to both the child and the parents for the best results. Activities that the child performs alone and with the family can give a picture of relationships and adjustments that relate to the child's health (see the care plan at the end of this chapter).

A challenge for nurses who work with school-age children is to maintain their normal healthy status and prevent illness. This task is accomplished through a variety of health-promotion mechanisms, such as examination, guidance, education, and legislation. The success of this health-promotion approach has been illustrated in at least one study in which black American children improved lifestyle choices when engaged in an intervention focused on cardiovascular health. Many professionals have noted that school-age children guided by the nurse generally seek health and use various resources to attain, maintain, or regain optimal health for their future productivity. Aspects of the nursing process are implemented when one is structuring a program to maintain the child's health (such as seen with an assessment of immunization status), promote health habits (seen with teaching bicycle safety), and prevent illness (seen by obtaining throat cultures to detect streptococcal infection).

Nurses have many opportunities and settings to help them implement their interventions as consultants, board members, and active providers of care. For example, nurses and school-age children interact during well-child evaluations and at school. Nurses in other roles, such as in public health positions and in hospitals, also play a role in health promotion, although these nurses must often focus more on helping the child and the family respond to an illness or a crisis. Local and national groups influence the health of children through their activities and regulations. These include organizations such as Boy Scouts and Girl Scouts, Big Brothers and Big Sisters, charities such

as the Red Cross, and government agencies such as the Consumer Product Safety Commission.

As an integral part of the community, the school system has the responsibility to provide a healthy school environment and a comprehensive health-education program. In some areas, nurses, physicians, and other health care personnel work as a team in the school health program, which includes health care and maintenance and education. The nurse advocates and searches for resources so that each child has a source of health care, or the nurse is a nurse practitioner who delivers care. School health programs range from an occasional mention of body care and the changes of puberty to a full program that integrates physical and mental health principles into all aspects of the educational experience.

Comprehensive school health services require an interdisciplinary, coordinated effort between health care providers and educators. Recommendations state that each school should have an on-site nurse to conduct and mentor students and faculty in health-promotion areas. Nevertheless, many schools share nurses because of budgetary concerns. However, when available, nurses offer educational and interpersonal skills to initiate health-promotion teaching that improves the overall health of consumers (students, parents, teachers, community). Nurses have a wide scope of practice, including that of referring parents to relevant resources aimed toward activities that improve the school environment and its inhabitants.

The nurse's role in planning health maintenance for children of a school varies, depending on the type of health maintenance program. In one system, the school nurse may refer children to resources available to provide a source of health care, whereas in another system, the school nurse functions as a nurse practitioner. On the basis of the scope of practice and state legal requirements, the school nurse monitors and updates children's immunizations and identifies and intervenes with children who have acute or chronic health care problems, such as scoliosis, strep throat, common cold, or child abuse. Increasingly, school nurses provide sophisticated care according to evidence-based protocols for chronically ill school-age children who

have been integrated into the regular academic environment. On the basis of state regulations, the nurse also engages in completing vision, hearing, and scoliosis screening at regular intervals. In most schools the nurse works with the school's physician, community physicians, and parents in meeting children's and community health needs.

For all school-age children, the school nurse plays a role in developing a healthy educational environment through promoting a comprehensive and age-appropriate health-education program focused on children becoming responsible for their own health. A program aimed at accident prevention in and around the school is part of the nurse's role. The program includes assessing the school for pedestrian and automobile traffic patterns, broken playground and classroom equipment, ice and snow dangers, poorly maintained toilet facilities, and inappropriately prepared food. Regular practice drills are held to acquaint teachers and students with emergency procedures (i.e., fire, bomb, or intruder threats or actual events; Box 20-12: Innovative Practice). All people in the school are prepared to respond to chemical hazards. The nurse implements existing school-based programs on drug and alcohol abuse.

Box 20-12

Innovative Practice

School Emergency Preparedness

Because children spend a significant portion of their day in school, pediatric emergencies such as exacerbation of a medical condition, behavioral crisis, and accidental/intentional injuries are likely to happen. As a result of the likelihood of such risks, the AAP (2015) and the AHA recommend the implementation of a medical emergency response plan (MERP). The purpose of a MERP is to establish procedures within the school for the administration of emergency first aid services, emergency treatments, and administration of emergency medications for students. A plan helps schools prepare to respond to life-threatening medical emergencies in

the first minutes before the arrival of energy medical service (EMS) personnel. All procedures established in the MERP are to be followed during school hours, at school-sponsored activities, and on school buses and other school property.

Because injuries are the most common life-threatening emergency encountered, teachers, trainers, school nurses, and other school personnel should be trained and know the general principles of first aid. Schools now employ fewer nurses, and school nurses often rotate between schools, resulting in many schools being without medical coverage for several hours/days each week. As a result, much of the emergency care is the responsibility of teachers and other school personnel.

The MERP should have the following core elements so as to save the greatest number of lives with the most efficient use of school equipment and personnel:

- Establish an efficient and effective campus-wide communication system for each school.

- Develop a coordinated and practiced MERP with the school nurses, physicians, athletic trainers, and the EMS system, with appropriate evaluation and quality improvement.

- Reduce the risk of life-threatening emergencies by identifying students at risk and ensuring that each has an individual emergency care plan and by reducing the risk of injury and disease triggers at the school.

- Train and equip teachers, staff, and students to provide cardiopulmonary resuscitation and first aid.

- Establish an automated external defibrillator program in schools.

A study assessing school disaster preparedness found only 12 states met the minimal standards of disaster preparedness in 2010 (Save the Children, 2012). School nurses play an important role and

should participate in all phases of planning and implementing all emergency preparedness and management plans as they pertain to school health and student safety (National Association of School Nurses, 2011).

Although many schools are in compliance with many of the recommendations for emergency preparedness, specific areas for improvement exist, such as practicing the MERP and ensuring the identification of authorized personnel in the case of an emergency. Preparedness of schools to manage life-threatening emergencies requires the commitment of the entire community. The nurse is in a prime position to facilitate these community efforts and orchestrate partnerships between school officials, local EMS, school personnel, and local pediatricians to ensure the planning and implementation of a disaster plan.

From American Academy of Pediatrics (AAP). (2015). *Children & disasters: Collaborative initiatives.* https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Children-and-Disasters/Pages/Collaborative-Initiatives.aspx; National Association of School Nurses. (2011). *The preparedness of schools to respond to emergencies in children: A national survey of school nurses*. *Pediatrics, 116,* e738–e745; Save the Children. (2012). Disaster preparedness for children in the USA. http://www.savethechildren.org.

It is also important to consider the role of the nurse in fostering a healthy social environment in the school. The nurse examines the social interactions of the children and interacts with them to promote positive relationships. However, social problems continue to constitute a major concern for many children during this time. Children may experience difficulty in making the initial transition away from the family and gaining satisfaction from a group of peers. Children may make the initial adjustment but then have difficulties interacting with others (e.g., bullying). When problems such as these arise, the nurse, parents, and school system determine the reasons for this behavior and intervene appropriately.

Nursing Application

The nurse working with the school-age child has a unique and exciting opportunity to engage the child in health-promoting behaviors. Most school-age children are able to participate in the teaching strategies if the strategies are geared toward the child's appropriate cognitive ability. As the age range of the school-age child is from 5 to 12 years, the nurse must consider the mental ability and comprehension of each developmental stage.

Nurses can teach health-promotion behaviors directly to the child through spending time demonstrating, monitoring, and reinforcing preventive health practices such as handwashing, dental hygiene, nutrition, and physical activity. These activities can be taught through age-appropriate reading materials, modeling, and role-playing. Engaging the child in these practices may also help the child conceptualize the link between the behavior and disease prevention. The nurse must partner with parents to model healthy behaviors at home, at school, and in the community settings.

A variety of methods can be used to educate children on health and nutrition. Keeping culture, socioeconomics, and media influences in mind, the nurse should teach children concepts about food choices, exercise habits, and the ways overall health is impacted by those choices. Nutrition education can be individualized to the age of the child through use of games, activities, colorful food guides, and simple cooking activities.

Physical activity in childhood is crucial in promoting healthy behaviors that continue into adulthood. Exercise for this age group is generally provided in group activities and sports. Physical activity provides the school-age child with peer interaction and social relationships. This aspect of health promotion should be encouraged by the nurse as well as the family.

As with younger age groups, health promotion of the school-age child focuses on education about routine health examination and the childhood immunization schedule. The nurse provides the families

with immunization recommendations and must remain updated on current guidelines. The nurse also focuses on prevention of childhood injuries by educating them about seat belt and bicycle safety, as well as other things with a potential for causing injury.

Screening for health problems is another aspect of caring for the school-age child. Screenings are generally conducted for problems with vision, hearing, height, weight, and oral health. The nurse may be the first person to identify a potential issue with regard to an acute or chronic condition. At that time, he or she gathers assessment data to determine if the child needs immediate treatment or a referral to another provider. For the nurse working with school-age children and their families, the role is often one of providing education, case management, consulting, counseling, and community outreach.

Case Study

Change in Usual Communication Pattern in School: Joey

Joey is an 8-year-old boy in elementary school. His teacher has voiced a growing concern regarding his classroom behavior. In the past 2 months Joey has become more withdrawn from his classmates and rarely participates in class discussion. This is a new behavior in that he “used to talk all the time, and raise his hand to answer questions in class.” His teacher reports that they were discussing family and family roles in class this week. Joey became very aggressive and yelled, “My dad isn't at home anymore ‘cause of my mom.” He went on to say, “I really miss dad. My mom's new boyfriend isn't nice and won't buy me stuff, like my dad does.” His teacher determines Joey's parents are divorced. A parent-teacher conference has been scheduled to discuss Joey's behavior because it is now affecting his grades in school.

Reflective Questions

- Is Joey's behavior appropriate for his age?
- Joey's parents do not understand his change in behavior. His father yells, "If she would let me spend more time with *my* son, Joey wouldn't be having trouble with school. She doesn't care about *my* son now that *she* has *her* new boyfriend." How might the nurse respond to this situation?
- What interventions might be effective for Joey's parents and teacher in improving his classroom behavior and school performance?

Care Plan

Change in Usual Communication Pattern in School: Joey

***NURSING DIAGNOSIS: Ineffective coping related to disruption of home environment**

Defining Characteristics

- Frequent absences from school (1 day per week in the past 2 months)
- Change in quality of schoolwork: grades have deteriorated in the past month
- Verbal outbursts in class

Related Factors

- Parents separated 9 months ago
- Lives with mother; her boyfriend moved into home 2 months ago
- Mom reports, "He frequently complains of headaches and

stomachaches, but his doctor can't find anything wrong." Results in frequent absence

- Visits father every other weekend
- No siblings

Expected Outcomes

- Child will decrease number of absences from school related to "headache/stomachache" complaints.
- Child's grades will improve during the 9-week period.
- Parents will become more involved with the school so as to establish a relationship with the school that addresses the needs of the child related to home and school.

Interventions (School Nurse)

- Assess level of family problems within the home regarding communication between parents and visitation with the child.
- Assess somatic complaints by the child. Have the child complete a "headache diary"/"stomachache diary" to determine aggravating/alleviating factors. Document the frequency of complaints and discuss/review them with the parents.
- Meet the child to assess academic and emotional needs as they relate to home and school. Discuss the findings with the child's parents.
- Meet the parents to develop a plan to help the child meet academic goals and address the emotional needs of the child. Involve the child's teacher in plan development.
- Offer community resources to address emotional needs of the child such as support groups for children of divorced parents, Boy's Club

of America, and peer play groups. Include information for parent support resources as well.

- Offer after-school tutoring to facilitate the meeting of academic goals as desired.

For further information on developing care plans, see Carpenito-Moyet (2016).

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Many changes occur in children during the exciting period of the school-age years. The child's development progresses from the immaturity of the preschooler to the beginning of adolescence and eventual adulthood. Cognitive abilities increase dramatically, adding to the desire to master tasks and the ability to develop moral judgment. The child's world expands beyond the family unit as school and peers begin to exert a major influence. Opportunities for nurses during this period occur primarily in ambulatory settings, with the school nurse frequently the most effective and influential health care provider for children of this age group and their families.

Adolescent

Susan Rowen James

OBJECTIVES

After completing this chapter, the reader will be able to:

- Summarize the physical growth, developmental, and maturational changes that occur during adolescence.
- Discuss the recommended schedule of health-promotion and preventive health visits for adolescents and the appropriate topics for inclusion during each visit.
- Analyze factors that contribute to risk-taking behaviors and situations during adolescence.
- Develop a health teaching plan addressing some of the physical, emotional, social, and spiritual challenges facing adolescents.

KEY TERMS

Acne

Adolescence

Anorexia nervosa

Binge eating disorder

Body image

Bulimia nervosa

Depression

Egocentrism
Ejaculation
Emancipated minors
Formal operations
Gynecomastia
Idealism
Identity
Introspection
Menarche
Menstruation
Nocturnal emissions
Obesity
Overweight
Peer group
Primary sexual characteristics
Puberty
Purge
Risk-taking behaviors
Role confusion
Scoliosis
Secondary sexual characteristics
Sexually transmitted infection
Tanner staging

Think About It

Risk Behaviors in Adolescents

The mortality rate for adolescents (age 15–18 years) is five times higher than

it is for school-age children (age 5–14 years). Currently, suicide is the second leading cause of death in adolescents (National Center for Health Statistics, 2014). Thirty-four percent of adolescents in the United States report being currently sexually active, and of those who are sexually active, 14% report not using any method of birth control (Centers for Disease Control and Prevention [CDC], 2014b).

- What growth and developmental factors make adolescents susceptible to engaging in risky behaviors?
- What anticipatory guidance and strategies might be offered to adolescents and their families to prevent this risky behavior?

The term *adolescence* is frequently used to describe the transitional stage between childhood and adulthood. The period of adolescence is defined as beginning with the onset of puberty, at approximately age 11 to 13 years. Many researchers and developmental specialists in the United States use the age span from 10 to 24 years as a working definition of adolescence. The term **adolescence** refers to the psychosocial, emotional, cognitive, and moral transition from childhood to young adulthood, whereas **puberty** refers to the development and maturation of the reproductive, endocrine, and structural processes that lead to fertility.

Rapid change in physical, psychosocial, spiritual, moral, and cognitive growth creates an extremely tenuous sense of balance. A pivotal developmental period, adolescence offers health care providers unique opportunities for providing health-promotion and preventive services to adolescents and their families. The CDC (2015a) emphasizes that focusing on adolescent health promotion also includes recognizing and enhancing protective factors against risk. These include positive parenting practices, parental engagement in the adolescent's education, and a strong parent-school connection. The US Department of Health and Human Services (USDHHS), Office of Disease Prevention and Health Promotion (2015) describes two major considerations that should concern health care providers in the upcoming years: practicing “cultural responsiveness” and providing

adolescents with opportunities to become competent through access to supportive relationships, health resources, and appropriate opportunities for optimal development. *Healthy People 2020* contains specific objectives related to adolescent health (Box 21-1: Healthy People 2020).

Box 21-1

Healthy People 2020

Selected Health-Promotion and Disease-Prevention Objectives for Adolescents

- Increase the proportion of adolescents who have had a wellness check-up in the past 12 months.
- Increase the proportion of adolescents who participate in extracurricular and out-of-school activities.
- Increase the proportion of adolescents who are connected to a parent or other positive adult caregiver.
- Increase the proportion of schools with a school breakfast program.
- Reduce the proportion of adolescents who have been offered, sold, or given an illegal drug on school property.
- Increase the proportion of middle and high schools that prohibit harassment based on a student's sexual orientation or gender identity.
- Decrease the proportion of public schools with a serious violent incident.
- Reduce adolescent and young adult perpetration of crimes, as well as adolescent and young adult being victims of crimes.

- Reduce the proportion of children and adolescents with untreated dental decay.
- Increase the proportion of adolescents who participate in daily school physical education.
- Increase the proportion of children and adolescents who do not exceed recommended limits for screen time.
- Increase the proportion of students in grades 9 through 12 who get sufficient sleep.
- Reduce the proportion of adolescents who report that they rode, during the previous 30 days, with a driver who had been drinking alcohol.
- Increase the proportion of adolescents never using substances.
- Reduce exposure to violence.
- Reduce suicide risk.
- Reduce suicide attempts by adolescents.
- Reduce the proportion of adolescents who engage in disordered eating behaviors in an attempt to control their weight.
- Reduce the proportion of children and adolescents who are considered obese.
- Increase the proportion of female and male adolescents who have never had sexual intercourse.
- Reduce tobacco use by adolescents.
- Increase educational achievement by adolescents.

From US Department of Health and Human Services. (2015). Healthy People 2020.

Biology and Genetics

Sex and Puberty

In contrast to the slow, steady growth of childhood, adolescents experience accelerated physical growth that dramatically alters their body size and proportions. Additionally, adolescents experience the onset of puberty. Changes associated with the onset of puberty occur in a predictable sequence, but the onset and duration of the sequence differ among individuals. Females usually begin puberty 2 years earlier than males and experience their growth spurt earlier. Demographic studies suggest that racial and ethnic differences in the ages of achieving pubertal milestones differ (Kaplowitz & Bloch, 2016). Biro and colleagues (2013) conducted a 4-year longitudinal study of more than 1200 girls aged 6 to 8 years and found that black girls showed breast development at least 1 year before white or Asian girls and at least 6 months earlier than Hispanic girls. They also found that white females are maturing earlier than in the past, and that body mass index is correlated with earlier onset of puberty. Adolescents who do not follow the normal sequence or who have not begun pubertal development by age 14 years, for males, and age 13 years, for females, should have an endocrine evaluation (American Academy of Pediatrics [AAP], 2015a,b).

The physical changes experienced during adolescence are mediated primarily by the hormonal regulatory systems in the hypothalamus, pituitary gland, gonads, and adrenal glands (Figure 21-1). The hypothalamus releases gonadotropin-releasing hormone (GnRF), which stimulates the anterior pituitary to release the gonadotropin hormones luteinizing hormone (LH) and follicle-stimulating hormone (FSH) (Copstead & Banasik, 2013). In females, this stimulates development of the ovaries and estrogen production. Once sexual maturation is complete, the ongoing release of hormones controls menses, pregnancy, and lactation. In males, luteinizing hormone results in enlargement of the testes and the development of Leydig cells in the testes, which produce testosterone. Follicle-stimulating

hormone stimulates the development of the seminiferous tubules of the testes, leading to spermatogenesis and fertility.

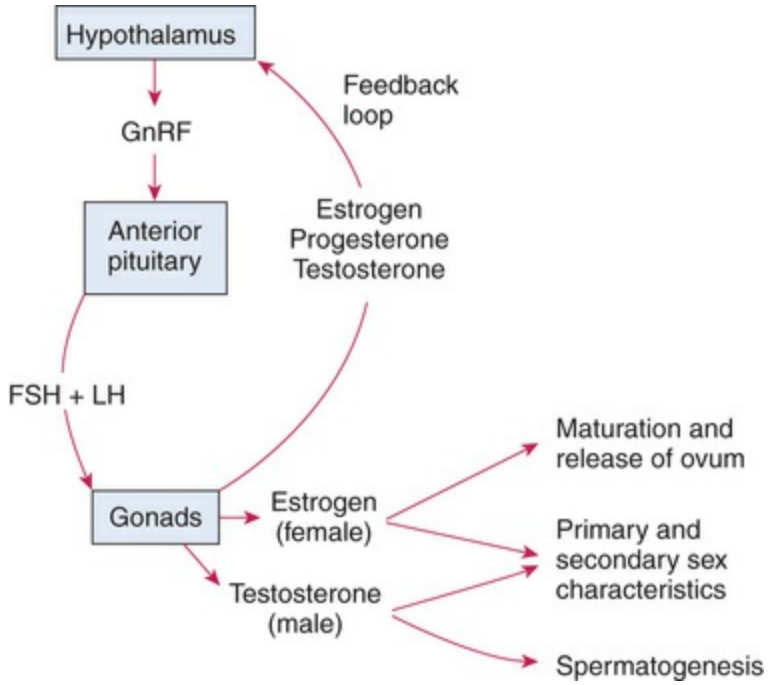

FIGURE 21-1 Hormonal interaction among hypothalamus, pituitary, and gonads. *FSH,* Follicle-stimulating hormone; *GnRF,* gonadotropin-releasing hormone; *LH,* luteinizing hormone. (From Hockenberry, M. J., & Wilson, D. [2015]. *Wong's nursing care of infants and children* [10th ed.]. St. Louis: Mosby.)

During puberty, **primary sexual characteristics** begin to develop and **secondary sexual characteristics** emerge. Primary sexual characteristics involve the organs necessary for reproduction, such as the penis and testes in boys and the vagina and uterus in girls. Secondary sexual characteristics are external features that are not essential for reproduction. Breast development, facial and pubic hair growth, and lowering of the voice are examples of secondary sexual characteristics (Table 21-1). Estrogen produces all secondary sexual characteristics except axillary and pubic hair, which are controlled by adrenal androgens. Sexual maturity rating, also referred to as **Tanner staging**, is used widely to assess and monitor the degree of maturation of an adolescent's primary and secondary sexual

characteristics. Each of the characteristics, breast, pubic hair, and genitals, is staged separately (from 1 to 5) and compared with the expected sequencing (Figure 21-2).

TABLE 21-1

GROWTH AND DEVELOPMENT
Sexual Maturity Rating, Tanner Stages: Developmental Stages of Secondary Sexual Characteristics

Stage	Male Genital Development	Pubic Hair Development	Female Breast Development	Other Changes
1	Prepubertal	No distinction between hair over pubic area and hair over abdomen		
2	Initial enlargement of scrotum and testes; reddening and texture changes of scrotum	Sparse growth of long, straight, downy hair at base of penis or along labia	Enlargement of areolar diameter; small area of elevation around papillae (breast bud)	Usual time of peak height velocity for girls
3	Initial enlargement of penis, mainly in length; further growth of testes and scrotum	Hair becomes dark, coarse, and curly; spreads sparsely over entire pubic area	Further elevation and enlargement of breasts and areolas, with no separation of their contours	Usual time of menarche; facial hair begins to grow on upper lip and voice deepens in boys
4	Further enlargement of penile diameter, testes, scrotum, and glans	Further spread of hair distribution, not extending to thighs	Areolas and papillae project from breast to form secondary mound	Usual time of peak height velocity for boys; axillary hair begins to grow
5	Adult in size and contour	Adult in amount and type; spreads to inner surface of thighs	Adult, with projection of papillae only; recession of areolas into general breast contour	

Modified from Hockenberry, M. J., & Wilson, D. (2015). *Wong's nursing care of infants and children* (10th ed.). St. Louis: Mosby.

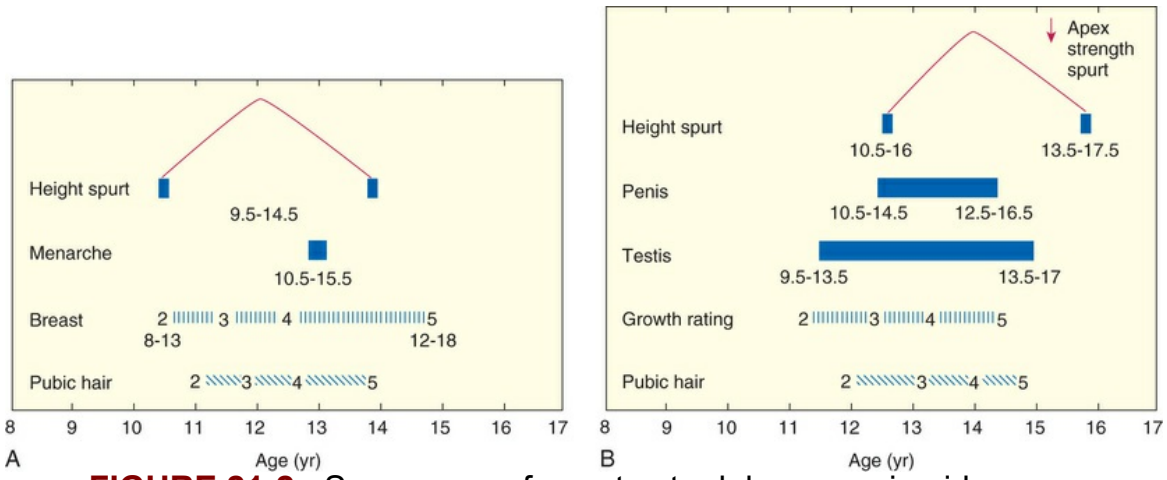

FIGURE 21-2 Sequences of events at adolescence in girls **(A)** and boys **(B)**. Single numbers *(2, 3, 4, 5)* indicate stages of development. The average is represented. A range of ages when each event may begin and end is indicated by inclusive numbers listed below each event. (Modified from Herman-Giddens, M., Slora, E. J., Wasserman, R. C., Bourdony, C. J., Bhapkar, M. V., Koch, G. G., et al. [1997]. Secondary sexual characteristics and menses in young girls seen in office practices: A study from the Pediatric Research in Office Settings Network. *Pediatrics, 99*[4], 505–512; Hockenberry, M., & Wilson, D. [2015]. *Wong's nursing care of infants and children* [10th ed.]. [Figs. 17-2 & 17-5]. St. Louis: Mosby; Marshall, W., & Tanner, J. [1970]. Variations in pattern of pubertal changes in boys. *Archives of Diseases in Childhood, 45*[239], 13–23.)

Breast development is usually confined to females; however, some degree of unilateral or bilateral breast enlargement, termed **gynecomastia**, may appear early in male puberty, just before the growth spurt. Gynecomastia is usually temporary and typically disappears. However, occasionally it persists and leads to body image problems and can be surgically reduced if psychological assessment warrants it.

The first sign of puberty in males is a thinning of the scrotal sac and enlargement of the testicles. **Ejaculation** is considered a milestone of male puberty and precedes fertility by several months. **Nocturnal emissions**, or wet dreams, can concern adolescent males because the events happen beyond their control.

For females, the first sign of puberty is the appearance of breast buds, followed by the growth spurt. The onset of **menstruation**, or **menarche**, occurs approximately 2 years after the appearance of the

breast buds and near the end of the growth spurt (see Figure 21-2).

Familiarity with the stages of development of sexual characteristics and their expected sequence helps the nurse monitor the adolescent's progression through puberty and detect any variations that might herald an alteration in normal growth and development.

Before the growth spurt, many adolescents experience a transient increase in the amount of body fat or adipose tissue. As puberty progresses the proportion of total body weight composed of fat usually declines, particularly in boys. Body fat begins to accumulate again in both sexes after their growth spurt, but at a slightly higher rate in females.

Other Physical Changes

The heart grows in size and strength. Blood volume and blood pressure increase, and the heart rate decreases to adult levels. These cardiovascular changes occur earlier in females, corresponding with puberty. Compared with adolescent males, adolescent females also generally have higher pulse rates and slightly lower systolic blood pressure. Adolescents are identified as hypertensive when their systolic or diastolic blood pressure is at or above the 95th percentile (based on age, sex, and height) on three separate occasions.

Respiratory rate decreases throughout childhood, reaching an average rate of 15 to 20 breaths per minute during adolescence. Respiratory volume and vital capacity increase, particularly in males. The larynx and vocal cords grow, producing the characteristic voice changes of puberty. Both male and female voices become deeper, and laryngeal cartilage enlarges, with both effects more pronounced in males.

The gastrointestinal system reaches functional maturity during the school-age years. However, it continues to grow along with the growth spurt (Guyton & Hall, 2011).

Permanent teeth begin erupting at approximately 6 years of age, and all 32, except the third molars, or wisdom teeth, are in place by 13 to 14 years of age. Third molars are often pulled during adolescence to make space for the other permanent teeth. It is not uncommon for one

or more of the third molars not to develop, and this lack of development (agenesis) is often familial.

The sweat and sebaceous glands both become more active during adolescence. The sweat glands are located primarily in the axillary, genital, and periumbilical areas and are the primary source of body odor. The sebaceous glands are located primarily on the face, neck, shoulders, upper back, chest, and genitals. They can become clogged and inflamed, leading to the common teenage condition called **acne**. Acne is seen in nearly all adolescents, and nearly 20% of adolescents experience moderate to severe manifestations. The prevalence is higher in females than in males (Bhate & Williams, 2013).

Scoliosis

During the growth spurt, adolescents may manifest signs of a common skeletal deformity called **scoliosis**, which is a lateral S-shaped curvature of the spine (Figure 21-3). The curve is typically convex to the right. Classifications of scoliosis include secondary or functional, congenital, neuromuscular, constitutional, and idiopathic, which has an infantile, juvenile, or adolescent onset. Approximately 10% of all adolescents have a mild truncal asymmetry; however, curves greater than 20 degrees are abnormal and can progress to significant curvature during the growth spurt (Honeyman, 2014; Manworren, 2013). Idiopathic scoliosis is the most common type and is significantly more prevalent in females. Early intervention is important because untreated scoliosis can result in disfigurement, impaired mobility, and cardiopulmonary complications. Evidence shows that early intervention in the form of scoliosis-specific physical therapy exercises or bracing can slow progression of curves and reduce the need for surgery, or, in children with mild scoliosis, reduce the need for bracing (Scoliosis Research Society et al., 2015).

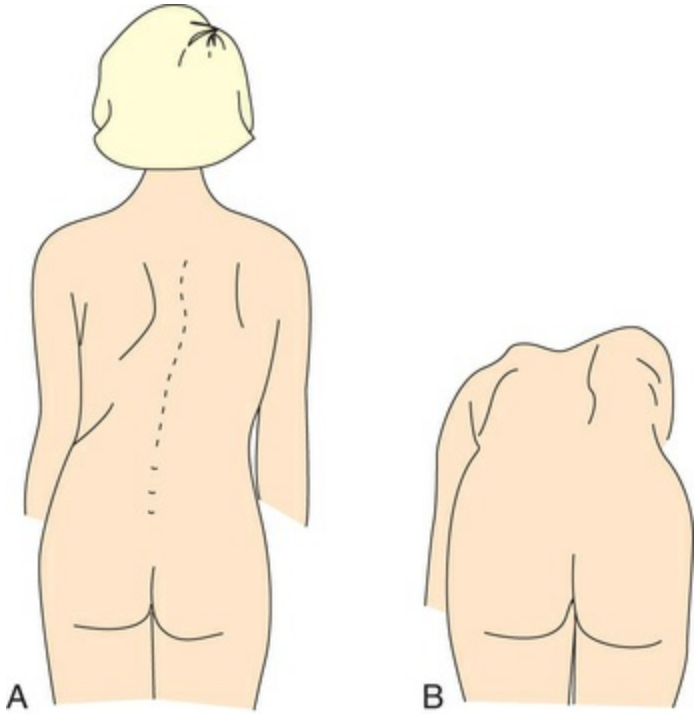

FIGURE 21-3 Scoliosis screening. So that the entire back can be seen, the adolescent should remove all clothing from the upper body when being assessed for scoliosis. **A,** While the adolescent stands up straight, check for any asymmetry; observe and palpate the body for differences in shoulder or scapular height, prominence of either scapula or hip, waist asymmetry, and misalignment of the spinous processes. Lateral curvature and thoracic convexity of the spine indicate scoliosis. **B,** With feet together, legs straight, and arms hanging freely, the adolescent bends forward until the back is parallel with the floor. Check for prominence of the ribs, or rib hump, on one side only and hip and leg asymmetry. With scoliosis, the chest wall on the side of convexity is prominent, and the scapula on the side of convexity is elevated.

The US Preventive Services Task Force (2015) has issued a statement that routine screening of asymptomatic children for scoliosis is not cost effective. However, the SOS, American Academy of Orthopedic Surgeons, Pediatric Orthopedic Society of America, and AAP (Scoliosis Research Society et al., 2015) support screening by a trained professional provider for girls at ages 10 and 12 years, and for boys at age 13 or 14 years. Referral for orthopedic evaluation occurs when the curvature measures more than 5 to 7 degrees, measured by a

scoliometer when the adolescent is in the Adams position (see Figure 21-3, *B*).

Genetics

Most genetic problems are discovered during infancy and early childhood. Some syndromes, however, may not be diagnosed until adolescence. Turner syndrome in females and Klinefelter syndrome in males result from alterations in the X chromosome. These genetic disorders, which affect both physical and cognitive development, are frequently discovered during the assessment of an adolescent who has delayed or irregular pubertal development, and require referral to an appropriate specialist.

Since the sequencing of the human genome, information on genetic predisposition to disease has expanded exponentially. For example, genomics research has demonstrated a genetic basis for conditions seen during adolescence, such as acne, scoliosis (Box 21-2: Genomics), substance dependence, depression, eating disorders, and autoimmune conditions (e.g., lupus erythematosus and celiac disease) (CDC, 2015b). The risk of conditions of concern to adolescents, such as breast cancer, type 2 diabetes, and cardiovascular disease, can now be identified through genetic testing. Although newborn screening for genetic disease is routinely performed, predictive screening for children and adolescents is not recommended because of unreliable interpretation and ethical considerations (Botkin et al., 2015). The AAP (2013a) has issued a policy statement that genetic testing should not be performed on children or adolescents unless clinically indicated. Predictive genetic testing on adolescents brings up ethical issues, especially regarding disclosure, and testing should be postponed until adulthood (AAP, 2013a; Botkin et al., 2015).

Box 21-2

Genomics

Scoliosis

For many years the cause of adolescent idiopathic scoliosis (AIS) has been elusive to determine. A body of research reveals that AIS is significantly more prevalent in girls than in boys (up to 10 times more prevalent), that AIS occurs in families, and that the condition is multifactorial. Multifactorial inheritance patterns suggest that a combination of genetics and environment affects the occurrence of a health condition. In the past several years, as genome sequencing has allowed more precise identification of genetic contributions to various diseases, multiple studies have tried to determine an exact genetic inheritance pattern for AIS. Researchers have identified multiple genes that possibly increase susceptibility and are associated with various aspects of spinal development and growth. These genes include those responsible for synthesizing proteins related to ossification, sensory development, collagen, estrogen production, and growth hormone. Unfortunately, researchers have not identified evidence that would suggest a specific genetic pattern, but have concluded that AIS is caused by multiple genes that are modified by environmental influences.

From Janusz, P., Kotwiki, T., Malgorzats, K., & Szulch, A. (2012). Genetic aspects of idiopathic scoliosis – literature review. *Scoliosis, 7*(Suppl 1), O71.; Krause, L. M., Buchan, J. G., Gurnett, C. A, & Dobbs, M. B. (2012). Polygenic model and sex dimorphisms in adolescent idiopathic scoliosis. *Journal of Bone & Joint Surgery. American Volume, 94*(16), 1485–1491; National Institutes of Health. (2016). Adolescent idiopathic scoliosis. https://ghr.nlm.nih.gov/condition/adolescent-idiopathic-scoliosis.

Family history, however, not only can help physicians make a diagnosis if the adolescent shows signs of a disorder but can also help to reveal whether there is an increased risk of a disease for the adolescent (Box 21-3: Innovative Practice).

Box 21-3

Innovative Practice

My Family Health Portrait

Teens can create a simple family pedigree with the Surgeon General's *My Family Health Portrait* at https://familyhistory.hhs.gov/FHH/html/index.html. *My Family Health Portrait* is a downloadable, Web-based tool for use on a personal computer. It helps individuals create their own family health history and is a part of the National Human Genome Research Institute and the US Surgeon General's Family History Initiative. Because it is Web-based, teens may be the family member best prepared (or most technologically comfortable) to coordinate the input of data. With their family's help, teens gather their family health history and then, using any type of computer, build a drawing of their family tree and a chart of their family health history. Both the chart and the drawing can be printed and shared with other family members and health care providers.

The Surgeon General's Family History Initiative began in 2004. It is suggested that families use holiday gatherings, such as Thanksgiving, when the family is present, to gather and record information for the family health history. In support of the family history initiative, the CDC (2015) has a website with various genomic resources as well (http://www.cdc.gov/genomics/famhistory/index.htm).

Centers for Disease Control and Prevention (CDC). (2015). Genomic tests and family history by level of evidence. http://www.cdc.gov.

Gordon's Functional Health Patterns

Health Perception–Health Management Pattern

Teens have fewer acute illnesses than younger children and fewer chronic illnesses than adults. They are seen in health care facilities less frequently than younger children and adults, and they rarely are hospitalized. Yet they need to be monitored, because adolescence is a pivotal developmental period with numerous physical, psychosocial, and spiritual changes. Box 21-4 lists interventions recommended for periodic health examinations for adolescents.

Box 21-4

Interventions Recommended for the Periodic Health Examination: 11 to 21 Years of Age

Screening

- Height, weight, and body mass index
- Blood pressure
- Scoliosis
- Vision and hearing
- Tanner stage
- Anemia
- Hyperlipidemia
- Urinalysis
- Tuberculosis—if at risk

- Eating disorders
- Sports injuries
- Tattoos and piercings
- Substance use assessment*
- Depression screening*
- HIV screening (age 16–18 years)*
- If sexually active, STI screening
- Counseling

Injury and Violence Prevention

- Lap and shoulder belts in car
- Bicycle, motorcycle, all-terrain vehicle helmets
- Protective gear for sports, work, and other physical activities
- Learn first aid and cardiopulmonary resuscitation
- Skin cancer, sun exposure (or exposure through tanning beds), sunscreen sun protection factor 15 or higher
- Safe storage and use of firearms

Substance Use

- Avoid tobacco, alcohol, and drug use
- Avoid alcohol or drug use while driving, swimming, boating, riding a bike or motorcycle, or operating farm equipment or other machinery

- Do not ride with a driver who has been using alcohol

Sexual Behavior

- Abstinence, resisting sexual pressures, saying no
- STI prevention and protection
- Unintended pregnancy, contraception
- Date rape

Diet and Exercise

- Choose a variety of healthy foods
- Balance caloric intake and energy expenditure
- Limit fat and cholesterol; emphasize grains, fruits, and vegetables
- Adequate calcium, iron, and folic acid

Dental Health

- Regular (every 6 months) visits to dental care provider
- Brush teeth at least twice a day and floss daily
- Avoid tobacco products

Immunization[†]

- Tdap vaccine (tetanus, diphtheria, acellular pertussis) at age 11 to 12 years; Td vaccine (tetanus, diphtheria) every 10 years thereafter
- HPV vaccine; boys and girls at age 11 through 12 years; three-dose series

- Meningococcal vaccine; one dose at age 11 to 12 years, booster dose at age 16 years
- Influenza vaccine yearly
- Catch up vaccines—hepatitis B; measles, mumps, rubella; varicella (two-dose schedule); hepatitis A (if indicated)

HPV, Human papillomavirus; *STI*, sexually transmitted infection.

A crucial component for understanding adolescent health is an adolescent's own perceptions of health, illness, and health care services. Too often their sense of invincibility and "Peter Pan" ideology couples with typical adolescent experimentation and **risk-taking behaviors** to produce deleterious health care choices and outcomes. Caught somewhere between childhood and adulthood, teens may no longer feel as if they are being attended to by pediatricians, pediatric nurse practitioners, and pediatric nurses, yet, at the same time, are often misunderstood by adult health care providers. Health care services for adolescents that are available, visible, confidential, and flexible need to be developed. Recent research (Hargreaves et al., 2015) demonstrates that unmet health care needs during adolescence can result in poor health outcomes during adulthood. The reasons that contribute to unmet health care needs include lack of appropriate access, financial constraints, and adolescent attitudes that health is not important. Whereas adults search for health information using the Internet, adolescents are more likely to use social media (e.g., Facebook, Twitter, on-line blogs) to obtain health information (Korda & Itani, 2013). Because these sites are unmonitored for accuracy, nurses need to advise adolescents and

their parents to verify information with their health providers. For information regarding health care services for adolescents, visit the National Adolescent and Young Adult Health Information Center (NAHIC) at http://nahic.ucsf.edu.

Adolescents are in the process of developing health habits and patterns of problem-solving that are likely to last a lifetime. The cognitive and psychological changes that they experience can affect their adherence to health-promotion and disease-prevention strategies. Teens do not always consider the health risks of their behavior and have an overall sense of invulnerability to illness or injury. Peer influence is primary, and parental input is often rejected. Parents need, however, to be vigilant to recognize when their adolescent needs assistance with avoiding situations that could lead to irreparable harm (AAP, 2015c). Parental monitoring, which involves knowing where the adolescent is, knowing with whom he or she is communicating, setting clear behavioral expectations, and sensitivity to adolescent behavior changes, has been shown to be protective against adolescent risk behavior. Role modeling appropriate health behaviors is also a known protective factor against risk (AAP, 2015c; CDC, 2012). Parents, however, need to guard against overprotection, sometimes known as overparenting, because this behavior can lead to overdependence and lack of confidence as the adolescent transitions to adulthood. Parents who are perceived by their children as being overcontrolling (e.g., give undue advice or assistance, are overly involved with the adolescent's activities, or fail to allow the adolescent to solve problems) can contribute to increased anxiety or stress, decreased self-confidence, and exaggerated egocentric behavior (Segrin et al., 2015). Nurses can advise parents to strike a balance between the desire to overprotect their children and allowing them increasing autonomy as adolescents become increasingly capable of more independent decisions about their health behavior.

Parents, teachers, and health care providers will be more successful in assisting teens to manage their health needs wisely if they treat them as joint partners in planning the care for which the adolescents themselves will assume responsibility. Key components of successful

health supervision include gradually facilitating adolescent independence and decision-making, involving parents and schools in a holistic approach to health promotion, and effective communication.

Nutritional-Metabolic Pattern

Although many adolescents gravitate to low-nutrient, processed foods, it is essential that they consume a well-rounded diet that provides a variety of high-nutrient, low-sugar, and low-fat foods and beverages (USDHHS & US Department of Agriculture [USDA], 2015). Adolescents need to consume daily calorie amounts appropriate for their level of physical exercise (females—1600–1800 calories; males—1800–3200 calories) found primarily in vegetables, fruits, whole grains, fish, and nuts. Nurses need to assist teens with following a healthy diet and educate them about the appropriate nutrients, such as protein (especially for vegetarians), calcium, and iron and folic acid (for females) (USDHHS & USDA, 2015). Recommending regular consumption of milk to prevent later osteoporosis is essential, especially for adolescent girls, as is avoidance of high-sugar and diet beverages. The nurse can encourage adolescents to eat breakfast every day to improve academic performance, or to carry protein snacks. An excellent resource for nurses and adolescents regarding dietary considerations is the MyPlate website: http://www.choosemyplate.gov/teens.

Many teens have concerns about their body, proper nutrition, and exercise. The media not only portray the ideal body as thin, lean, or muscular, but at the same time promote access to unhealthy high-fat, high-sugar, processed foods. Asserting their newfound autonomy, teens may choose dietary intake as a mechanism to gain control over their changing bodies, exert independence, or experiment with a new **identity** or cause, such as becoming a vegetarian. All of this occurs as their body's nutrient and energy demands increase in preparation for and in response to the adolescent growth spurt. Teen activities, including sports and other vigorous extracurricular physical activity, can further increase these demands. Gymnasts, runners, bodybuilders, rowers, wrestlers, dancers, and swimmers are particularly vulnerable

to eating disorders because their sports necessitate weight restriction. Complicating matters are teens' overwhelming desire to “fit in” with their peers, which often prevails and can lead to unhealthy dietary practices

Eating Disorders

The occurrence of eating disorders results from a combination of genetic and environmental factors, mediated as well by internal and external factors prevalent during puberty (e.g., family, peer, and media influences) (Kreipe, 2016). In the United States the lifetime prevalence of eating disorders among adolescents is 0.3% (Swanson et al., 2011). Major eating disorders include **anorexia nervosa**, **bulimia nervosa**, and **binge eating disorder**. In general, eating disorders have a higher prevalence in females, but they affect both sexes and people of all cultures (Kreipe, 2016). Most adolescents with an eating disorder experience comorbid psychiatric conditions, such as anxiety, depression, or obsessive-compulsive disorder, and suicide ideation is not uncommon (Kreipe, 2016; Swanson et al., 2011). Adolescents who meet the criteria for eating disorders should be referred to an interdisciplinary team that is experienced and skilled in working with these disorders

At one end of the eating disorder spectrum is anorexia nervosa and bulimia nervosa. At the other end is binge eating disorder and **obesity**. Adolescents with anorexia nervosa are typically female, perfectionists, and high achievers. Symptoms or warning signs include a relentless pursuit of thinness, self-starving with significant weight loss, lack of menstruation (in females) and decreased sexual interests (in males), compulsive physical activity, preoccupation with food, portioning food carefully, and eating only small amounts of only certain foods.

The adolescent may also have brittle hair and nails; dry, yellowish skin; growth of fine hair over the body; constipation; mild anemia and muscle weakness; and often complains of feeling cold. The severe restriction of food intake eventually contributes to dangerous malnourishment, and, in some cases, death. The onset of anorexia

nervosa is typically in response to low self-esteem and real or imagined obesity.

Distorted **body image** is a hallmark of anorexia nervosa in both males and females. Body image specifically refers to the picture of and feelings about various characteristics of one's body. In females particularly, distorted body image may be related to self-objectification, or judging one's personality or character strictly by one's appearance (Slater & Tiggermann, 2015). Media images and positive or negative comments about appearance from others can contribute to self-objectification (Slater & Tiggerman, 2015).

Bulimia nervosa has symptoms or warning signs that are different from those of anorexia nervosa. Teens with bulimia nervosa typically binge on huge quantities of high-calorie foods and then **purge** by self-induced vomiting and/or use of laxatives. Binge episodes may alternate with diets, resulting in dramatic weight fluctuations. These teens often try to hide the signs of vomiting by running water as a sound cover. Purging poses serious threats to the teen's health, including dehydration, sometimes fatal electrolyte imbalances, and erosion of tooth enamel.

At the other end of the eating disorder spectrum is binge eating disorder, which can often contribute to obesity. Similarly to the teen with bulimia nervosa, the teen with binge eating disorder frequently consumes large amounts of food while feeling a lack of control over eating. However, this disorder is different from bulimia nervosa because these teens usually do not purge their bodies of the excess food they consume during their binge episodes. Adolescents who are binge eaters experience lack of control over eating, the inability to stop eating when full, social difficulties, altered mood, and decreased self-esteem (Pasold et al., 2014).

The obese adolescent consumes too many calories for the amount of energy expended. Studies have shown a strong correlation between inactivity, such as viewing television, playing computer games, and Internet surfing, and the tendency to be **overweight**. Other research has identified depression as one of the strongest predictors of adolescent obesity. Obesity can be detrimental to adolescents' self-

esteem and social development, because they often become trapped in a vicious cycle of social rejection, isolation, inactivity, and continued obesity. Adolescent obesity has a poor prognosis, with most obese adolescents becoming obese adults. In addition, obesity increases the risk of and occurrence of type 2 diabetes mellitus.

School nurses may be the first to notice a possible eating disorder in students. Questioning students who come to the health office can elicit warning signs (Obadina, 2014). The nurse can ask: Do you have concerns about your weight or think you are fat? How often do you weigh yourself? How often do you exercise? Has your diet changed recently (become more picky with foods, not controlling eating, hiding food, counting calories excessively)? Are you still doing fun activities with friends?

Because of the multiple factors contributing to the occurrence of an eating disorder, there is no one method that can prevent its occurrence. However, when working with families of adolescents, nurses can recommend family members deemphasize the adolescent's body proportions or shape, encourage healthy eating and participation in regular exercise, emphasize the adolescent's positive and unique aspects, and foster the adolescent's self-esteem (Obadina, 2014).

Obesity, Type 2 Diabetes, and Teens

Soaring obesity rates are making type 2 diabetes, a disease that used to be seen mostly in adults older than 45 years, more common among teens and young people. Diabetes is a group of diseases marked by high levels of glucose in the blood, which, left unattended, lead to blindness, kidney failure, amputations, heart disease, and stroke. Type 2 diabetes, formerly called adult-onset diabetes, is the most common form. People can develop it at any age. However, being overweight and inactive increases one's risk. Teens can access information about weight control with *Take Charge of Your Health! A Guide for Teens* available at http://www.win.niddk.nih.gov/publications/take_charge.htm. Furthermore, the National Diabetes Education Program (NDEP) has

now developed a new "Tips for Teens" series that includes a tip sheet on how to lower the risk of type 2 diabetes that is "teen-friendly." Nurses can direct high-risk teens or teens with type 2 diabetes to visit the NDEP website at http://ndep.nih.gov/teens/LowerYourRisk.aspx.

More than anything, adolescents need reassurance about their bodies. Parents, teachers, and health care providers will be more successful in helping teens assume responsibility and manage their ongoing health needs if they approach and treat them as partners in planning their care. Assessment is of particular importance. Nurses working with adolescents need to be aware of abnormal changes in weight, body image distortion, abnormal food behavior, including thinking about food, and obsessive exercise (Martin & Golden, 2014). Nurses can engage adolescents and help them create an individualized wellness plan that addresses body image, diet, weight concerns, and physical activity.

Elimination Pattern

The renal and gastrointestinal systems are functionally mature by adolescence, and elimination patterns are consistent with those found in adults. Abnormal variation can occur in teens with eating disorders. It is important to remember that an adolescent's need for privacy or self-protection may inhibit normal elimination in public places, such as schools.

Activity-Exercise Pattern

During adolescence the alterations in body composition and growth of lean muscle mass allow the teen to experience increased physical strength and endurance. All adolescents should be taught that regular exercise can increase their endurance and improve their appearance and general state of health and that these positive effects can extend into adulthood.

Many teens participate in organized sports, and the preparticipation sports examination is one of the most common reasons adolescents seek primary care (Figure 21-4). This examination offers an

opportunity for nurses to identify adolescents at risk, evaluate their general state of health, and promote healthy lifestyle behaviors (Box 21-5). Along with eating disorders related to maintaining or losing weight for sports participation, adolescent athletes are subject to overuse injuries. Often these injuries are related to the specific sport in which the adolescent engages. The sports environment can contribute to or prevent overuse. The factors contributing to injury include environmental temperature (too hot or too cold), type of playing surface, emotional pressure from parents or coaches, inappropriate equipment, and inadequate training of coaches (Kerr et al., 2013). Nurses need to work closely with athletes and coaches to be sure the approach to sports participation is healthy and free of injury potential.

FIGURE 21-4 Adolescents frequently participate in organized activities, especially sports.

Box 21-5

Adolescent Preparticipation Sports Examination

Areas for Special Concern

- Previous trauma, including concussion
- Cardiovascular disease
- Hypertension
- Asthma
- Seizure disorder
- Splenomegaly, or enlarged spleen, often seen with infectious mononucleosis
- HIV infection
- Absence of paired organs: eye, kidney, testicle, or ovary

Sleep-Rest Pattern

During adolescence the amount of time needed each night for sleep declines in comparison with earlier childhood needs. Although their sleep patterns differ greatly, adolescents need at least 9 hours of sleep per night (George & Davis, 2013). Adolescents who are employed, those involved in extracurricular sports, and those who have "too much on their plate" are at increased risk of sleep deprivation. They stay up late and are then forced to wake up before their sleep cycles have finished because the high school day has such an early start. Many adolescents send and receive text messages at bedtime after room lights have been turned off, which can interfere with a good night's sleep. Even a moderate level of nighttime texting can greatly increase the likelihood of having long-term fatigue. Adolescents without sufficient sleep can find it difficult to concentrate and learn,

or even stay awake in classes. Too little sleep might also contribute to mood swings and behavioral problems. Adolescents who drive when they are sleep deprived can cause accidents, which could lead to death. Nurses can suggest that adolescents keep their cell phones, computers, and other electronic devices out of their bedrooms at night. Nurses can also suggest strategies for daily living that help adolescents cope with the challenge of balancing their varied responsibilities while preventing exhaustion or burnout.

Cognitive-Perceptual Pattern

Piaget's Theory of Cognitive Development

Adolescence is characterized by a shift in cognitive abilities to Piaget's stage of **formal operations** (Piaget, 1969). Piaget's theory used the term *formal* to represent the emergence of ability to focus on the "form" of thoughts, objects, and experiences rather than on the exact content, which in turn lays the groundwork for abstract thinking. These new cognitive abilities are reflected in adolescent behaviors in several ways.

The first change is that, because of their new ability to "think about their thinking," adolescents become highly introspective. As introspection increases, they develop an internalized audience that provides them with a means to evaluate questions such as "Who am I?" "How do others see me?" and "Where am I going?" **Introspection** also combines with a reemergence of **egocentrism**, leading to their sense of being the primary focus—special, unique, and exceptional (Piaget, 1969). Being exceptional adolescents means being the exception, thinking that nothing can happen to them, but only to others. This type of thought can contribute to the risk-taking behaviors for which adolescents are well known:

- I can get drunk on weekends and not develop a drinking problem.
- I won't get pregnant; I've had sex for 6 months and haven't gotten pregnant yet.
- I can take those turns at 60 miles per hour and not lose control.

Another behavioral manifestation of adolescents' formal operations is an intolerance of things as they are. They are able to conceptualize things as they might or could be, rather than how they are, and can think of elaborate means for achieving these changes—now. With this newfound capability, they constantly challenge the ways things are and challenge themselves to consider the way things can or should be. Teens can be vehement in trying to convince others of their viewpoints and untiring in their support of causes that align with them. This **idealism** can lead to a rejection of family beliefs, religion, or social causes, which do not appear to the adolescent to be working fast enough to solve the problems of society. Although this idealism appears to most adults to be a flight from reality, it is a necessary stage in formal thinking. Reality is recognized, but only as a subset of many other possibilities that need to be aligned with their own thinking. Eventually, their thinking becomes less egocentric and omnipotent, giving way to an appreciation of differences in judgment between themselves and others (Piaget, 1969).

Erikson's Theory of Psychosocial Development

Erikson's theory of psychosocial development describes the central task of adolescence as being the establishment of identity, with the primary risk being **role confusion** (Erikson, 1968). Although it may appear that adolescents are involved in a final rather than a transient or initial stage of development, identity formation in adolescence provides a means of moving into and through what might be termed an identity crisis.

This crisis involves a restaging of each of the previous stages of psychosocial development (Erikson, 1968). Development of trust in self and others, as emphasized in infancy, is encountered again as the adolescent searches for people and ideologies in which to have faith. Toddlerhood, and its search for autonomy, is also revisited as adolescents search for independence from their primary family units. The preschooler's challenge, a sense of initiative rather than guilt, resurfaces as the adolescent searches for direction and purpose. The school-age child's developing sense of industry is carried into the

adolescent period also, as teens make choices in social, recreational, volunteer, academic, familial, and occupational activities. The confusion and hesitation in making these choices arise from fears of participating in activities that will not afford them the opportunity to excel or win the approval of their peers.

Erikson (1968) says that the extent to which these earlier tasks were accomplished successfully predicts the success of the current developmental stage, therefore influencing an adolescent's resourcefulness and success in experimenting with the new identity. When the threat of identity confusion is exceedingly great, delinquent behavior and alterations in mental health can occur. This threat is enhanced by conditions of poverty, racism, and other social inequities (see Box 21-13).

The pursuit of a meaningful ideology and an individual identity frequently creates a puzzling combination of shifting interests and sudden extremes in action. Erikson views this behavior as an attempt to try on various roles and to search for some stable principle that might last through the testing of extremes and be carried into adulthood. Reassuring parents that this behavior is normal during adolescence and encouraging them to maintain positive communication with their adolescents is an important nursing function.

Time Orientation

Adolescents look at time differently than they did as younger children. They realize that the response to a problem can, and sometimes should, be delayed to think through the possibilities for approaching the problem. Additionally, teens develop a future orientation and are able to delay immediate gratification to gain more satisfaction in the future.

Language

Advances in cognitive skills are reflected in an increased understanding of language. Formal operations and more abstract

thought processes require expression in different words than did the more concrete thoughts of younger children. Adolescents give complex definitions, frequently including all possible meanings or uses. Interpretations of pictures or stories are intricate and abstract. Older teens are capable of using and understanding complex sentence structure, although they, like adults, may not use these complex sentences routinely in their speech.

Both receptive and expressive vocabularies increase during adolescence. As with all ages, receptive vocabulary far exceeds expressive vocabulary. The adolescent's vocabulary frequently includes slang. Slang may be centered on topics such as drug use, popular dress, music, and certain peer activities, or it may be more pervasive, in which case adults or "outsiders" may have difficulty following a conversation between two teens. The surge in cell phone use, instant and text messaging, and on-line social media has given rise to an entirely new set of communications to decipher (Table 21-2).

TABLE 21-2

Deciphering and Conversing in the Latest Text Messaging Lingo

Message	Meaning
GR8	Great
LOL	Laughing out loud
BRB	Be right back
AFC/AFK	Away from computer/away from keyboard
POS/MOS/DOS	Parent over shoulder/Mom over shoulder/Dad over shoulder
9	Parent watching
99	Parent no longer watching
CD9	Code 9: parent watching or in room
RUOK	Are you ok?
XLNT	Excellent
F2F	Face to face
Zzz	Sleeping, bored, tired
Y	Why
B4N	Bye for now
YYSSW	Yeah yeah sure sure whatever
PCM	Please call me

Self-Perception–Self-Concept Pattern

The term *self-perception,* which is often used interchangeably with the

terms *self-concept* and *self-esteem*, refers to both the description of the self and to the evaluation of, or feelings about, that description. Tied together and brought to the forefront in adolescence, both self-perception and body image dominate, influence, and are influenced by individual, peer, and societal norms and expectations.

Assessment, anticipatory guidance, education, and counseling are strategies the nurse can use to guide the adolescent in developing a self-perception that incorporates a healthy body image. It is important for parents, teachers, and health care providers to remember to praise adolescents for who they are rather than for what they do, value each of them as unique, demonstrate belief in their abilities to grow and develop, and delight in their discoveries of themselves and their unique means of expressing this.

Acne

Teenage acne can influence self-perception, as it is a contributor to alterations in appearance. Most adolescents experience some degree of acne, especially during puberty, and they are typically concerned about their skin changes. The sebaceous glands increase production of sebum, a primary factor in the pathogenesis of acne. The sebaceous follicles become clogged with sebum and debris, forming open (blackheads) or closed (whiteheads) comedones. The incidence of acne within families suggests that hereditary factors are involved.

Thorough examination of the adolescent's skin and a discussion of its impact on the overall body image are necessary to determine appropriate management strategies. Intervention should include teaching the individual about the pathophysiological nature of acne. Knowledge allows the adolescent to become instrumental in its management and helps dispel common myths about acne and its care.

The approach to acne management is a stepwise approach according to the severity; all recommended management strategies take between 6 and 8 weeks to be effective (Gailbraith, 2016). Washing the skin with mild soap and water two times a day is the best way to remove surface dirt and oil. Daily topical administration of a retinoid or topical benzoyl peroxide is recommended for all cases of acne.

Recent guidelines from the American Academy of Dermatology (AAD) (Zaenglein et al., 2016) suggest that a combination of topical agents (benzoyl peroxide, retinoid, antibiotic) can be used for mild acne. Should the condition worsen, or be more severe than mild acne, management can include adding an oral antibiotic to the topical regimen (Zaenglein et al., 2016). Systemic treatment with isotretinoin is used only for severe or moderate nonresponsive cases (Zaenglein et al., 2016). Vigorous scrubbing should be discouraged because the skin can become irritated, leading to follicular rupture (Well, 2013). The adolescent should not attempt to remove the pustules and papules that form. Squeezing the lesion can result in further irritation of the gland and permanent injury to the tissue. Adolescent females need to be careful when selecting makeup. Most preparations, when applied extensively over the face, prevent adequate exposure to air and light, especially those that have a fat base. Sunlight can have a beneficial effect on acne; however, prolonged exposure should be avoided. Stress can exacerbate acne in some adolescents. In these cases, stress-management techniques should be considered. The effect of diet on acne is a highly controversial issue. Evidence indicates that dietary restrictions specific to acne are unnecessary.

Adolescents with acne need support and understanding. The nurse can help adolescents and their families understand that management does not result in immediate improvement. In fact, topical agents may make acne appear worse initially, with any improvement occurring slowly over several months.

Body Art and Piercing

Adolescence is a developmental period full of identity experimentation and risk-taking behavior. Body piercing and tattooing have become popular forms of expression of identity, particularly among adolescents, and are intimately related to self-perception. Each carries health risks and potentially fatal complications.

There are very few sites on adolescent bodies that have not been pierced. Ears, nipples, navels, noses, and eyebrows have all

succumbed to metallic rings, rods, studs, and barbells. However, relatively frequently, an adolescent who obtains a piercing suffers a complication. Most commonly these include localized infection, bleeding, dermatitis, and possible keloid formation. Intraoral soft tissue piercing of the lips, cheek, uvula, and tongue harbors additional and potentially fatal complications, including a constant risk of aspiration, hemorrhage, and swelling leading to airway compromise, nerve damage, keloid scar formation, abscess, and tetanus. There is also an increased risk of hepatitis and HIV infection, as well as tooth injury, gingival recession, and difficulty with speech, taste, and swallowing.

Tattooing carries similar risks of infection, with a heightened concern for the transmission of blood-borne diseases, including hepatitis and HIV infection, especially with colorful tattoos. Colored ink is expensive and is often reused to cut costs, increasing exposure risks. Tattoos are also permanent markings and do not age well.

Nurses can explore with adolescents the reasons for acquiring body art and explain the potential short-term and long-term consequences to assist with their decision-making. To prevent infection from body piercing, the nurse needs to advise the adolescent to use meticulous handwashing when cleaning piercing sites. The sites should be cleaned with saline or antibacterial soap and protected from injury (AAD, 2015). Adolescents with new tattoos need to avoid sun exposure and apply a moisturizing lotion to the site (AAD, 2016). With both types of body art, adolescents should notify the provider of any signs of infection.

Roles-Relationships Pattern

Families

Until adolescence, the younger child is highly dependent on the parents and other adults. Striving for identity and increased independence, the adolescent begins to spend increased time away from the family. Parents sense a narrowing of their influence as their teen not only begins to prefer the company of peers and other adults

but also begins to question familial beliefs and values. Parents may respond by setting unreasonably strict limits and asking intrusive questions about their teen's activities, friends, and ideas or decide to drop all rules and limits and assume that the adolescent can now manage alone. Neither of these approaches works well.

Whereas adolescents strive for a sense of identity and independence, their parents try to learn how to let go. Each is temporarily unsure of the relationship with the other, and the family unit may experience more stress than at any previous time. Furthermore, this period is often prolonged because more teens remain financially dependent on their families as they move into young adulthood.

Some families experience better outcomes than do other families. Families in which parents maintain a willingness to listen and demonstrate an ongoing affection for and acceptance of their adolescent yet still maintain some consistent limits experience more constructive, positive outcomes during this period. This situation does not mean that parents necessarily agree with their teen's ideas or actions, but rather that they are willing to hear what the adolescent has to say and to negotiate some limits. Parents may need assistance in determining negotiable versus nonnegotiable rules and in developing ways to voice their concerns in an honest, open way. Even when teens do not want to “discuss” a topic, they need to know why their parents are concerned.

Peers

Faced with the need to become autonomous, achieve identity, and become productive, the adolescent often turns from the family to the peer group to find a safe psychosocial shelter in which to develop. Belonging to an informally organized clique, crowd, gang, or group is the primary means with which to make the transition from the young child's allegiance to the family to a member of a group. Identification with a group is proclaimed through conformity to standards of clothing, behavior, language, and values. This feature of the adolescent subculture persists despite the strong inclination in society

as a whole toward greater levels of individuality.

The **peer group** is a vehicle for disengaging from the family unit and, as such, provides a means of achieving the goals of independence and individualization. Adolescents talk a great deal with their peers. Whether on the phone, on-line, or in person, they can discuss a 10-minute situation for hours on end. This sharing of thoughts and impressions is important. The telephone or computer can provide a "safe" mechanism for the teen to interact with members of the opposite sex as they share intimate ideas and concerns and begin to experience the closeness and caring that develops into the capacity to form a future intimate relationship.

Adolescents in both urban and rural areas can have exposure to, and participate in, gangs. Gangs function as a peer group for adolescents who may feel socially inadequate, have problems at school, or exhibit low self-esteem (Melde & Eskensen, 2014). Feeling unsafe in a community or at school may also be a contributing factor (Lenzi et al., 2015). Not all gangs exhibit delinquent behavior; however, there is a societal perception that violence is part of the gang culture. Nurses can alert parents to the signs that their adolescent may be associating with a gang; these include wearing symbolic clothing, new and extensive body art, secrecy about friends, worsening school performance, and possible substance use (AAP, 2015d). Encouraging strong and positive relationships with friends during adolescence and increased vigilance by parents can be protective against gang membership.

Sexuality-Reproductive Pattern

Adolescent Sexual Issues

The emergence of secondary sexual characteristics increases adolescents' awareness of themselves as sexual human beings. They fantasize about relationships and sex and gradually experiment with dating and a myriad of coital and noncoital physical contacts. Adolescents become sexually active for a variety of reasons. They have sex for affection, because of peer pressure, as a symbol of

maturity, as spontaneous experimentation, to feel close, or because it feels good or right. Although the prevalence of adolescent sexual activity in the United States has decreased, approximately 34% of teens report being sexually active (CDC, 2014b). At times, they have intercourse without their consent. Approximately 7.3% of adolescents report forced intercourse, and approximately the same percentage report physical battering by a date (CDC, 2014b). (See the case study and care plan at the end of this chapter).

In the process of establishing a sexual sense of themselves, it is not uncommon for adolescents to question if they are homosexual. Experimenting with same-sex physical intimacy does not necessarily predict future sexual orientation, but feelings associated with the possibility of homosexual identity can give rise to anxiety, mood disorders, and heightened risk of suicide in adolescents, especially if they feel victimized by others (Lim et al., 2013). Approximately 5% to 10% of people in the United States identify themselves as being what may be referred to as "gender nonconforming" (Lim et al., 2014). An important goal stated in *Healthy People 2020* (USDHHS, Office of Disease Prevention and Health Promotion, 2015) is to "improve the health, safety, and well-being of lesbian, gay, bisexual, and transgender (LGBT) individuals." A primary reason for the identification of this goal is the recognition that many health providers, among others, have a negative attitude toward caring for individuals with gender differences (Lim et al., 2013). In addition to emotional issues associated with gender nonconformity, nurses need to educate themselves about health issues associated with adolescents in this population. These include risk of acquiring a **sexually transmitted infection** (STI), increased tobacco use, substance use or abuse, and obesity (Lim et al., 2013, 2014). When providing culturally appropriate care, nurses can create a supportive, nonjudgmental climate that enables disclosure and optimizes social support for both adolescents and their families (Lim et al., 2014).

The technological revolution has opened up a limitless world of unmediated information to adolescents and has led to increased issues of on-line risky behaviors. The use of on-line social networks such as

Facebook, Twitter, Instagram, and other messaging sites continues to increase rapidly among all age groups and segments of our society, presenting new opportunities for the exchange of sexual information, as well as for potentially unsafe encounters between predators and the vulnerable or young. Additionally, adolescents who use the Internet to seek sexual information often receive conflicting messages and inaccurate facts. Sexting has been recognized as an increasing occurrence for several years and is a global practice among teens and young adults. Sexting refers to sending a text message with sexually explicit content or a sexually explicit picture. This type of texting can cause emotional pain for the person in the picture, as well as the sender and receiver. Nurses help adolescents understand that text messages should not contain pictures of naked people or of people kissing or touching each other, and that sending such a type of text message is considered a crime in some areas.

Knowing adolescents are heavily invested in these and other sexual issues, nurses are capable of discussing and willing to discuss them with adolescents in a variety of settings, such as physicians' offices, clinics, and schools. Nurses need to be comfortable with their own sexuality; able to discuss the subject of sex and sexual orientation, contraception, and protection against STIs; and be aware of their own limitations, beliefs, and biases. Anticipatory guidance about the decision to become sexually active, to use contraception, and to obtain protection from STIs needs to be provided before adolescents encounter a situation in which they need this information (see Tables 22-2 and 22-3). This is also a good time to introduce the adolescent to breast and testicular self-examinations (Box 21-6: Quality and Safety Scenario).

Box 21-6

Quality and Safety Scenario

Performing Breast and Testicular Self-Examination

Breast self-examination (BSE) or testicular self-examination (TSE)

should be performed once a month so that teens become familiar with the usual appearance and feel of their breasts or testicles. This routine makes noticing any changes from one month to another easier. Finding a change from "normal" is the main idea behind regular self-examination. The best time for females to perform a BSE is 2 or 3 days after their period ends, when the breasts are least likely to be tender or swollen. For males, the best time for a TSE is during or immediately after a warm shower.

Breast Self-Examination

- Stand in front of a mirror. Inspect both breasts for anything unusual, such as any discharge from the nipples, puckering or dimpling of the skin, or marked asymmetry.

- While watching closely in the mirror, clasp your hands behind your head and press your hands forward, and inspect the breast again.

- Next, press your hands firmly on your hips and bow slightly toward the mirror as you pull your shoulders and elbows forward, and inspect the breast again.

- Next, raise one arm. Use three or four fingers to explore the breast firmly, carefully, and thoroughly. Beginning at the outer edge, press the flat part of your fingers in small circles, moving the circles slowly around the breast. Gradually work toward the nipple. Be sure to examine the entire breast. Pay special attention to the area between the breast and the armpit, including the armpit itself. Feel the breast for any unusual lump or mass under the skin.

- Gently squeeze the nipple and look for a discharge. Repeat the examination on the other breast.

The last two steps should be repeated lying down. This position flattens the breast and makes examination easier. Some women perform BSE in the shower. Fingers gliding over soapy skin make concentrating on the texture underneath easier.

Testicular Self-Examination

- Cup or support the testicles with one hand and feel them with the other.
- Gently roll each testicle between the thumb and fingers. There should not be any pain.
- Feel the testicles for any swelling or hard lumps on the surface of the testicles. Testicles are normally oval, firm, smooth, and rubbery. One may be slightly larger than the other.
- A natural tubelike structure, the epididymis, is along the back of the testicle. Learn what it feels like.

From Lowdermilk, D. L., Perry, S. E., & Cashion, M.C. (2011). *Maternity nursing* (8th ed.). St. Louis: Mosby; Neinstein, L. S., Gordau, C. M., Katzman, D. K., Rosen, D. S., & Woods, E. R. (2008). *Adolescent health care: A practical guide* (5th ed.). Philadelphia; Lippincott Williams & Wilkins.

School nurses are often leaders of, or participants in, school-based sex education programs. Depending on the philosophy of the educational district, sex education programs can be abstinence only or comprehensive, which combines abstinence with discussion of protective measures. Evidence shows that neither of these is totally effective in delaying adolescent sexual intimacy, but both provide straightforward information, which adolescents need (Grossman et al., 2014; Rohrbach et al., 2015). Grossman and colleagues (2014), noting that comprehensive sex education programs have had mixed results on adolescents delaying intimacy, studied the effect of the addition of a parental component to a standard sex education program. Their hypothesis was that this component would facilitate sharing of values between children and parents, as well as increasing the comfort of parents in communicating sexual information to their adolescents. They used a longitudinal study design to follow more than 2400 sixth grade students in 24 schools until they reached eighth grade; schools were randomly assigned to the parent involvement

group, and the control group and students were surveyed each year. They found that a higher percentage of students in the experimental group delayed sexual activity, and that the addition of parental involvement enhanced protective effects, especially for middle school boys (Grossman et al., 2014). Nurses need to also consider not only parental beliefs and values regarding the provision of sex education in the schools but also what is the optimal age for introducing information. Children are entering puberty earlier than in the past, and sex education programs focusing on positive relationships may need to begin at an earlier age than middle school (Jennings, 2015).

Adolescent Pregnancy

For health care providers, adolescent pregnancy is viewed as a high-risk situation because of the serious health risks and potential complications for both the mother and the infant. For politicians and governmental agencies, it is a social problem that makes overwhelming demands on social and economic resources. For adolescents and their families, it may be seen as positive and normal or the worst disaster imaginable. No matter what the perspective, adolescent pregnancy represents a myriad of concerns with far-reaching social, educational, financial, and emotional effects.

Recent information from the National Center for Health Statistics (Ventura et al., 2014) reveals that births to girls aged 15 to 19 years in the United States number 273,105, or a birth rate of 26.5 per 1000. The overall teen birth rate has dropped dramatically by approximately 57% in the past 2 decades, and this has occurred in all ethnic groups. The birth rate is highest in Hispanic teens, followed by non-Hispanic blacks, American Indian/Alaskan Natives, non-Hispanic whites, and Asian Pacific Islanders.

Adolescent pregnancy has a myriad of negative outcomes for both the mother and the child. For the mother, these include a significant decline in her future prospects, especially educational and economic; single parenthood; reliance on government-sponsored assistance, and poverty (Ng & Kaye, 2012). For the child born to adolescent mothers there is a higher risk of low birth weight. Low birth weight, which

may result from disparities in access to prenatal care, is associated with infant death and other health and developmental problems (Ventura et al., 2014). Furthermore, these children often fall victim to abuse and neglect and suffer from poor school performance.

When pregnancy occurs, adolescents and their families deserve honest and sensitive counseling about options available to them, as well as the support systems available for them throughout the pregnancy, birth, and subsequent parenting. Nurses not only need to reinforce reproductive health-education efforts but also need to encourage adolescents to build on the strengths in their lives and opportunities available to them (see Chapter 22 for additional information about pregnancy and contraception).

Coping–Stress Tolerance Pattern

When all the changes that occur in adolescents are aligned with their need to separate from their parents and gain a sense of their own independence, their ability to cope is put to the test over and over again. Common coping mechanisms, and the strategies the nurse can use to encourage teens to use them in adaptive ways, are listed in Box 21-7.

Box 21-7

Coping Mechanisms of Adolescents

Cognitive Mastery

The adolescent attempts to learn as much as possible about the situation or stressor. This strategy is common for the adolescent with a chronic illness. The nurse can assist by clarifying any misinformation, sharing research findings, and encouraging a discussion of feelings.

Conformity

The adolescent attempts to be a mirror image of peers, which includes dress, language, attitudes, and actions. The nurse must respect this

need for sameness and can also encourage discussion of feelings about differences among teens.

Controlling Behavior

Adolescents must be in charge of some aspects of life and can no longer accept family and school rules without question as they did in the past. This need for control extends to health care. The nurse cannot simply give directions or instructions, but rather should present the options and allow the adolescent to partner with the nurse to work out an acceptable plan.

Fantasy

The adolescent may use fantasy as a way to escape or experiment. The nurse can encourage the teen to use fantasy constructively to develop creative plans to deal with a stressful situation.

Motor Activity

Engaging in sports, dancing, running, or other physical activity can be an effective tension-releasing strategy, and can also provide an instant peer group. The nurse can encourage physical activity and offer information about protective gear and injury prevention.

However, too often adolescents are unable to balance the stresses, lacking the appropriate skills and outlets, adequate support systems, or available mental health intervention. Depression, suicide, and substance abuse emerge as life becomes overwhelming and the future unimaginable.

Depression

As with many other diseases, the rate of **depression** increases with age, and the incidence continues to increase during adolescence. Approximately 11% of adolescents experience a major depressive disorder by age 18 years, with the prevalence in girls almost twice as high as in boys (Forum on Child and Family Statistics, 2015). The term

depression includes both major depressive and dysthymic disorders. A major depression is an alteration in mood that is disabling and interferes with normal activities, whereas dysthymia is a depressed or irritable mood that extends for more than 2 years but does not interfere with activities or performance (National Institute of Mental Health, 2011).

Depression is suspected when the adolescent uses words such as down, sad, low, blue, hopeless, worried, bored, or discouraged and exhibits several of the following symptoms:

- Change in weight or appetite
- Insomnia or hypersomnia
- Decreased energy or fatigue
- Loss of interest and pleasure in usual activities
- Out-of-proportion feelings of self-reproach or guilt
- Difficulty concentrating; declining school performance
- Preoccupation with death or suicidal ideation

The AAP has recommended routine screening for mental health disorders in the primary care setting using a reliable and valid assessment instrument (Weitzman & Wegner, 2015). Evidence suggests that when parents complete a mental health screening questionnaire for their children during regular health-promotion visits, referrals for appropriate mental health management increase (Jonovich & Alpert-Gillis, 2014). Nurses need to lead the way in screening and assessing children and teens for mental health problems, including depression. Moreover, nurses may promote mental health promotion in both children and teens by teaching them effective coping skills and stress-reduction techniques.

Suicide

Adolescence is a period of considerable stress, and when coping mechanisms and social supports are inadequate, suicide may emerge as an outcome. Suicide has become the second leading cause of death among adolescents, aged 15 to 24 years (National Center for Health

Statistics, 2014). A national survey revealed that 17% of youths in grades 9 to 12 in the United States reported that they were seriously considering suicide and 8% had attempted suicide during the previous year (CDC, 2014b). These figures might not even reflect the full scope of the problem because many suicides may be classified as accidental deaths. Along with well-known risk factors, such as depression or substance abuse, the risk factors for suicide may be related to physical and cognitive developmental changes. The physical and emotional changes during puberty in younger children evolve into older adolescents achieving a cognitive level that allows them to more carefully solve problems and look at consequences (Fried et al., 2012). Many researchers are convinced that suicide during adolescence is not an impulsive or spontaneous act: it is selected carefully only after other problem-solving methods have failed and suicide is viewed as the only option.

Adolescent suicide can be prevented. Distressed adolescents tend to give clues, both verbally and nonverbally. Any single clue may mean nothing, but when several clues are noted, they should be recognized as important warning signs. Box 21-8 outlines vigilant warning signs for parents, teachers, health care providers, and peers to prevent adolescent suicide. Any signs of suicide or threat to commit suicide should be taken seriously and require immediate intervention and referral. An adult should remain with the adolescent until medical assistance becomes available. Nurses can teach adolescents to be sensitive to the signs that may indicate a friend is suicidal and to seek adult assistance immediately.

Box 21-8

Warning Signs of Suicide Risk in Adolescents

Behavioral Changes

- Increased risk taking

- Increased incidence of accidents
- Substance use and abuse
- Physical violence to self, others, or animals
- Decreased appetite
- Alienation from family or peer group
- Giving away personal items
- Writing letters or notes, essays, and poems with suicidal content

Cognitive and Mood Changes

- Expression of hopelessness
- Increasing rage or anger
- Dramatic swings in affect
- Sleep disorders
- Preoccupation with death
- Difficulty concentrating
- Hearing voices, seeing things or people
- Newfound interest in religion or cult

Values-Beliefs Pattern

Values and beliefs are learned phenomena that serve as guides for decision-making and actions. With the development of abstract thought, adolescents begin to expand their understanding of good and bad or right and wrong, to include autonomous moral principles that

have validity apart from the authority of a parent or society and instead are based on the individual's beliefs. Their newly discovered maturity in moral reasoning is situational and relational and is often superseded by psychosocial developmental needs and influences. Adolescents may think or feel something is wrong or bad yet may act contrary to that belief because of peer pressure or the need to declare their independence.

Adolescents often align their values and beliefs with a particular religion, philosophical school of thought, social movement or cause, or other formal system, using it to make decisions about what is right or wrong, best or worst, and important or trivial. During adolescence, these alignments can change drastically and often, causing strife and concern for parents, yet providing the teen with different ranges of experience from which to base eventual and lasting choices.

Kohlberg's theory of moral development (Kohlberg, 1981) demonstrates that the adolescent begins to make the transition to the postconventional stage, equating what is right with the idea of justice and basing actions on the recognition of the universal principles underlying laws and social agreements. Gilligan and colleagues (1990), who developed a parallel theory of moral development for females, proposes that the female adolescent sees “good” as involving self-sacrifice and caring for the relationships in her life. They state that, as moral reasoning matures, the female adolescent learns to achieve a balance between what is good for her and what is good for others in her network of relationships.

As adolescents struggle with their journey to discover who they are, parents, teachers, and health care providers need to provide positive role modeling, reinforce positive behaviors, and remember the difficulty of their own journeys. It is often when we like them the least that they need us the most.

Environmental Processes

Because adolescents are in developmental transition, their lifestyle choices may have a significant effect on their current and future health. These choices are particularly sensitive to the immediate physical and social environments. These environmental influences include their family members, friends, community, school, neighborhood, and work environments. Several critical types of adolescent health behaviors—including alcohol and drug use, injury and violence, tobacco use, nutrition, physical activity, and sexual behaviors—have been identified as contributing to the leading causes of death and disability among adults and youth.

Physical Agents

Unintentional Injury

Unintentional injury, along with suicide and homicide, continues to be the leading cause of death and injury during adolescence. Approximately 66% of all deaths from unintentional injury among adolescents, aged 15 to 19 years, are attributed to injuries caused by motor vehicle crashes (National Center for Injury Prevention and Control, 2013). Motor vehicle crashes are a significant cause of nonfatal injury as well. Whether drivers, passengers, pedestrians, or cyclists, few adolescents take measures to reduce their risk of injury, with 7.6% rarely or never using a safety belt and 87% rarely or never using a bicycle helmet (CDC, 2014b). Evidence also suggests that distractions, such as talking or texting on cell phones, eating, or playing with the radio, increase teen drivers' risk of being involved in a crash.

Nurses talk to teens about the consequences of texting while driving and encourage teens to wear their safety belts and avoid driving, or riding with someone, under the influence of drugs or alcohol. The tendency to play loud music and change the tune or disc often, as well as the pressure to answer cell phones, can also be distracting, as can a

car full of other teens. Recognizing this and that teens have a much higher nighttime crash fatality rate, many states have enacted new driver restrictions and nighttime curfews.

Sports Injuries

Organized sports in and out of school provide adolescents with experiences in competition, teamwork and effort, and conflict resolution. They also provide a valuable means for adolescents to develop self-esteem. However, adolescents are particularly vulnerable to sports injuries. Their coordination skills are developing, their judgment is often immature and inadequate, their epiphyses have not yet closed, and their extremities are poorly protected by stabilizing musculature. They can also become obsessed or driven to perform beyond their capabilities or to the exclusion of all other activities. The use of performance-enhancing substances, such as steroids, which have been unfortunately modeled by many professional athletes, can create another potential extreme scenario that places the adolescent at risk of injury.

Although traumatic brain injury (concussion) is caused by falls or other mechanical injury, the most frequent contributing factor in children and adolescents is participation in sports (Rivera et al., 2015). Even a minor impact injury to the head or neck, with or without loss of consciousness, can result in long-term physical, emotional, and cognitive effects if it is not appropriately managed (Arbogast et al., 2013). The signs and symptoms of concussion in children include deficits in cognition, altered neurological status, problems concentrating in school, and fatigue. Traumatic brain injury should be managed by a provider who is experienced in recognizing the signs and symptoms and who is experienced in concussion management. Several reliable and valid assessment instruments are available to assist health care providers in diagnosis (Rivera et al., 2015). As a consequence of a body of evidence suggesting that traumatic brain injury effects can be more severe in children and adolescents, many states have enacted "Return to Play" legislation (Rivera et al., 2015), which guides parents, coaches, and health providers in appropriate

management. Conservative management is essential and may involve restricting all physical activity and ensuring cognitive rest (no school work; restriction of use of electronic devices, such as television, video games, computers, or phones) until the adolescent is no longer symptomatic (Arbogast et al., 2013; Rivera et al., 2015). Decisions regarding return to activity and school are often based on a stepwise staging system ranging from 1 (no activity until asymptomatic for 24 hours) to 6 (return to full activity with medical clearance) (Rivera et al, 2015).

The nurse advocates the proper use of protective gear during all activities and a thorough preparticipation sports examination, along with concussion training for coaches and parents. The nurse also monitors adolescents for overuse, overexertion, or overinvestment in a sport.

Violence

Although the rate of adolescent victims of violence has decreased in the past 2 decades, adolescents still experience risk of injury and death from violence in their homes, schools, and communities. In the United States the rate of adolescents, aged 12 to 17 years, being victims of violent crime is 9 per 1000 adolescents (Forum on Child and Family Statistics, 2015). Adolescents can be perpetrators of violence as well, and homicide is the third leading cause of death in adolescents older than 15 years (National Center for Health Statistics, 2014). Figure 21-5 outlines the interrelationships of internal and external precipitating factors that increase an adolescent's vulnerability to and for violent behaviors. Many teens report carrying weapons to protect themselves or intimidate others. Adolescents often report a fear of violence and try to avoid situations where they might be vulnerable to it, including the home or even the bathroom at school. Victims of violent crime can experience both short-term and long-term physical and psychological health problems.

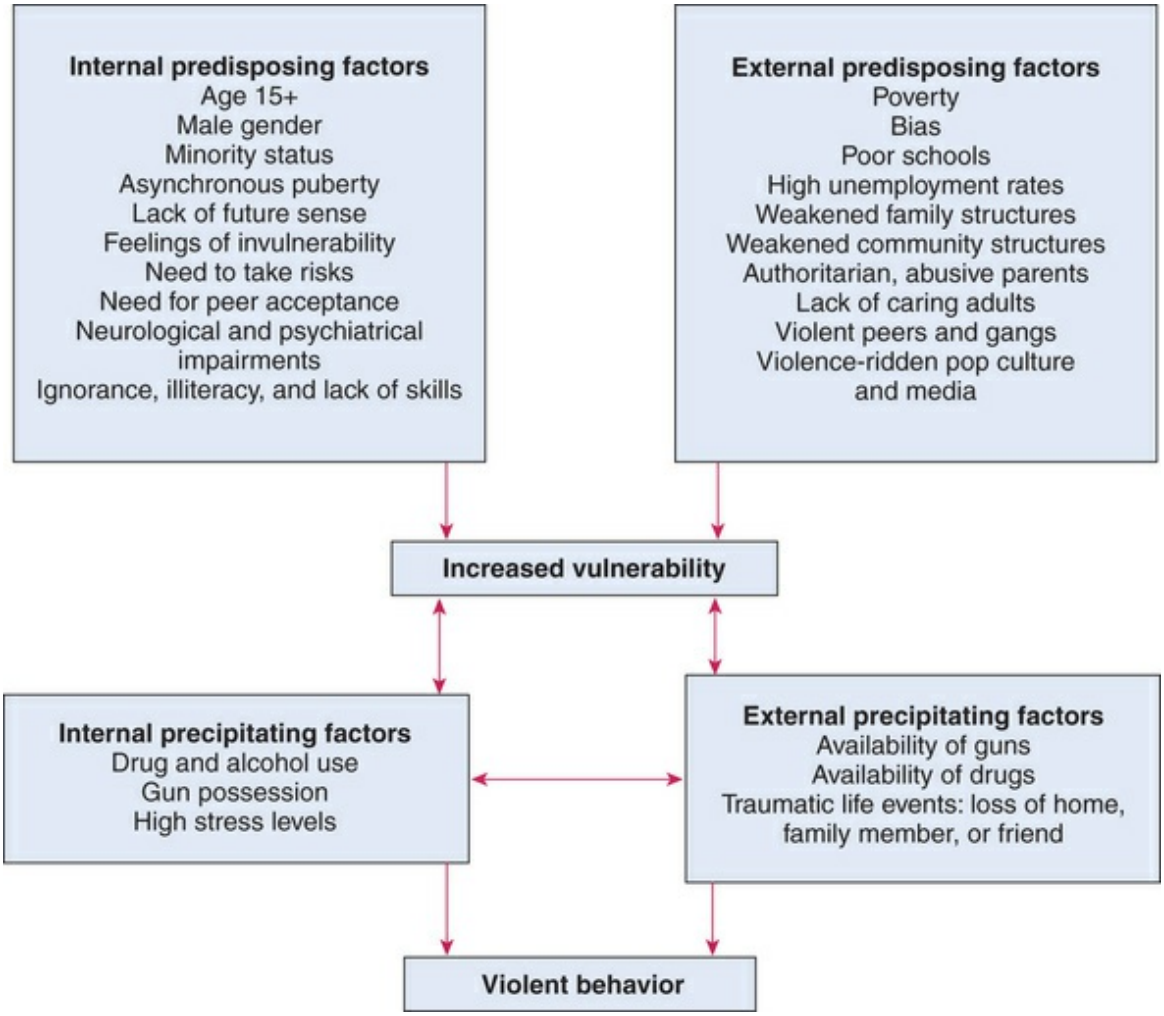

FIGURE 21-5 Factors contributing to adolescent violence.

Becoming increasingly independent, adolescents test the limits of authority, experiment with a variety of roles, question adult values and authority, and look to peers for affirmation. They may feel pressure to join gangs or feel threatened by them. Many studies suggest that witnessing or observing violence, whether in person or projected on the television, video, or movie screen, results in a higher incidence of aggressive or violent behaviors (You, 2014). Graphic violence in the media, current music lyrics, and video gaming has also been implicated in increased violent behavior.

Teenagers may be involved in physical or emotional bullying and/or cyberbullying. Cyberbullying refers to emotional bullying via electronic media, such as harassing texts, e-mails, or instant messages,

and social media posts (Carter & Wilson, 2015). A recent study (Carter & Wilson, 2015) of the prevalence of cyberbullying among 367 adolescents shows that 16.9% of them reported being victims of cyberbullying, and 30.1% were victims of traditional bullying. With a significant majority of adolescents having access to technological devices, bullying can occur on a much wider and more destructive scale (Carter & Wilson, 2015). Receiving bullying text messages or being harassed on social media can make a teen feel insecure and may lead to school absences or serious emotional distress, including, in extreme cases, suicide.

Nurses engage adolescents, examining and discussing the messages in videos, songs, movies, games, and television shows. Discussing their developing sense of self, their sense of belonging and where that sense is found, and their fears may help nurses to intercept an adolescent who might otherwise turn to violence. Discussing frightening news events with adolescents in a realistic, contextual way might also help nurses mitigate fear and anxiety. Teens who are valued and nurtured by caring adults have the best chance of emerging from adolescence unscathed. Nurses may also discuss cyberbullying with adolescents; encourage them to talk to a trusted adult if he or she receives harassing text messages and to consider options such as rejecting texts from unknown numbers; and tell them that it is inappropriate to send harassing text messages to others. The warning signs of cyberbullying are similar to those that occur with any type of bullying and include decrease in school performance or reluctance to attend school, increased signs of stress, isolation from friends, and altered sleep or eating patterns (National Society for the Prevention of Cruelty to Children as cited in "Reducing the impact of bullying: Useful resources and guidance," 2015).

Working with parents is essential. Nurses can encourage parents to be vigilant regarding their adolescent's use of electronic media, including restricting use or using parental controls, if necessary. The AAP (2013b) recommends limiting total screen time to no more than 2 hours a day for children of all ages and removing access to all electronic device at bedtime. Parents need to be aware of websites

accessed by their adolescent, including YouTube sites, gaming sites, text messaging programs, and social media. Adolescents may be resistant to parental monitoring because of the perception that it invades their privacy; however, nurses can suggest that parents discuss these issues with teens before providing them with electronic access so that adolescents know from the outset that spot checking will occur and the consequences of inappropriate use.

Biological Agents

Infection

Infectious mononucleosis is a self-limiting viral infection transmitted by direct contact with oropharyngeal secretions. It is prevalent among adolescents and is often referred to as the "kissing disease"; however, it can occur in younger children. It is caused by Epstein-Barr virus. Typically, adolescents complain of a sore throat, lymph node enlargement, and lethargy. Both splenomegaly and hepatomegaly can occur, creating a risk of injury. The condition is self-limiting and resolves with symptomatic care and appropriate rest.

The rates of meningococcal disease remain highest for infants, but recently rates have increased among adolescents. Reports have identified an increased risk of meningococcal disease among college first-year students who live in dormitories or residence halls, particularly if they are exposed to secondhand smoke. Many colleges now require meningococcal vaccination, along with other vaccinations administered during childhood. Meningococcal vaccine is now being given routinely to adolescents, with a first dose administered when the adolescent is 11 to 12 years old, and a booster dose at age 16 years (Advisory Committee on Immunization Practices [ACIP], 2016).

Adolescents are at the period of life with high sexual energy that may lead to high levels of risk-taking behaviors attributable to an increased sense of invulnerability. As adolescents experiment with and explore their sexual development and emerging independence, they engage in risky sexual behavior and expose themselves to increased risk of acquiring STIs. STIs most commonly include

gonorrhea, syphilis, chlamydia, herpes simplex virus infection, human papilloma virus (HPV) infection, trichomoniasis, hepatitis B, and HIV infection. Approximately 50% of the newly diagnosed STI cases in the United States are among adolescents and young adults, and approximately 25% of sexually active girls have an STI, most commonly HPV infection or chlamydia (CDC, 2014b). Minorities, especially black Americans, are disproportionately infected with HIV (CDC, 2015b).

Many contributing factors have been identified and found to negatively impact this significant public and adolescent health problem. Factors such as inconsistent use of contraceptive and protective devices, increasingly earlier age of and more frequent sexual activity, lower self-esteem, depression, social and peer pressure, and an adolescent's sense of invincibility were related to higher risks of STIs. On the other hand, factors such as high self-efficacy, effective parent-child communications, parental monitoring, positive school relationships, and sexual knowledge could be significant protective factors to reduce the risk of STIs in adolescents (AAP, 2015a).

Several theories have been used to guide the practices of preventing sexual risk-taking behaviors in adolescents. The health-promotion model (Pender et al., 2010) has been used by nurses for the development of sexual risk-reduction interventions for adolescents, and these interventions were found to be effective. Most of the cognitive-behavioral interventions that stem from these theories report effectiveness in reducing the risk of HIV infection. Scientific studies show that well-designed and well-implemented HIV infection/STI prevention programs can decrease sexual risk behaviors among adolescents (Box 21-9: Research for Evidence-Based Practice). Although adolescents can be evaluated and treated for STIs, the diseases must be reported and the nurse must be aware of the government rules about reporting.

Box 21-9

Research for Evidence-Based Practice

An Effective Prevention Program for Adolescents' Sexual Health

Regardless of advances in prevention and treatment, STIs continue to be a significant cause of morbidity and death in the United States. Promoting the ability of children and adolescents to avoid risk-taking sexual behaviors is considered a significant approach to encourage sexual health in adolescents. Standard comprehensive sex education programs have had mixed results in adolescents delaying sexual activity, so Rohrbach et al. (2015) investigated a novel sex education program—a rights-based program. They defined rights-based education as including factual information, along with information about gender and human rights, right to self-determination, and empowerment. Their randomized controlled design compared a standard sex education program with the rights-based program and assessed whether the rights-based program would have long-term results. They surveyed participants before the program initiation and 1 year later and found that the program had a long-lasting positive effect on participants' psychosocial outcomes, but not necessarily on sexual behaviors, although there was an increase in adolescents' use of clinic services for sexual concerns (Rohrbach et al., 2015). Including principles of gender rights and empowerment in a sex education program provides students with additional strategies to determine when they are ready for sexual activity.

From Rohrbach, L. Berglas, N., Jerman, P., Angulo-Olaiz, F., & Chou, C. (2015). A rights-based sexuality education program for adolescents: 1-year outcomes. *Journal of Adolescent Health, 57*(4), 399–405.

Nurses are aware of the cultural issues that may play a significant role in the prevention of STIs in adolescents, such as HIV/acquired immunodeficiency syndrome (AIDS). While nurses develop interventions for reducing STI-related sexual risk behaviors, they take adolescents' cultural/ethnic backgrounds into considerations.

Cancer

Adolescents are affected by many of the same cancers as are younger children, such as leukemia, osteogenic sarcoma, lymphomas, and central nervous system tumors. Older adolescents are entering the period of their lives during which cancer of the reproductive and related organs is more common. For females the focus is on cervical and breast cancer; for males, testicular cancer is of concern.

The peak incidence of breast and cervical cancer is during middle age and breast and cervical cancers are actually rare in the teenage years. Risks for later development of these cancers can occur during adolescence, so prevention and surveillance are essential. Breast self-examination, which has been highly recommended for many, has recently been questioned as a routine practice for most adolescents. The extremely small incidence of breast cancer in teens has caused some health care providers to deemphasize this practice for them. However, most still feel that regular examination of the breasts begins a lifelong habit that should begin as soon as the female adolescent develops (see Box 21-6: Quality and Safety Scenario).

Cervical cancer is detected with a Papanicolaou (Pap) smear, obtained from the cervix during a pelvic examination. Information from the Center for Young Women's Health, Boston Children's Hospital (2015) describes factors that increase the risk of cervical cancer, which include early initiation of sexual intercourse, having multiple sexual partners or a sexual partner who has had many partners, any history of STIs in the adolescent or partner, and lack of condom use. Sexually active adolescents should be screened for STIs, which may not require an internal pelvic examination. A pelvic examination with or without a Pap smear is indicated for symptoms of infection or gynecological problems, but no longer routinely; however, all women should have a pelvic examination with a Pap smear beginning at age 21 years (American College of Obstetricians and Gynecologists, 2012).

Administration of a vaccine to prevent cervical cancer and other diseases caused by certain types of genital HPV has been recommended by the ACIP (http://www.cdc.gov/hpv/). An HPV

vaccination series is recommended for girls and boys at age 11 or 12 years (ACIP, 2016). The vaccine is also recommended for all adolescent girls and women through age 26 years who did not receive all three doses of the vaccine when they were younger, and for all adolescent boys and men through age 21 years (age 26 years if they are in a sexual relationship with another man) who also did not complete the vaccine series when they were younger (CDC, 2015c). Ideally, females should get the vaccine before they are sexually active. This is because the vaccine is most effective in girls/women who have not yet acquired any of the HPV types covered by the vaccine (CDC, 2015c). Females who are sexually active may also benefit from the vaccine, but they may receive less benefit because the vaccine will have no effect on HPV types they acquired before vaccine administration. The vaccine protects against HPV-related cancers in both boys and girls.

Testicular cancer is the number one cancer in adolescent and young adult males. Adolescent males should learn to perform a testicular self-examination and should continue this practice monthly (see Box 21-6: Quality and Safety Scenario). Nurses introduce and teach methods of self-examination to adolescents, who naturally are interested in their developing bodies.

Chemical Agents

Substance Use and Abuse

Adolescents are influenced by a complicated interaction between biological and psychosocial development, environmental messages, and societal attitudes regarding the use of substances such as alcohol, tobacco, or marijuana. Society as a whole is increasingly oriented toward using chemicals such as drugs, alcohol, and tobacco to feel better, look better, act more sociable, stay awake, sleep, be sexy or erect, or lose weight. Some of the most famous music, movie, and sports stars openly model substance use and abuse. It is no surprise that adolescents are making the choice to experiment with and use substances at younger and younger ages.

Alcohol is the substance used most frequently by adolescents (CDC, 2014b), with nearly 35% of adolescents reporting current use in a national survey. Alcohol use is followed by marijuana use (23.4%), use of prescription medications (17.8%), and use of inhalants (e.g., glue or other aerosols; 8.9%). Although overall heroin use has appeared to decrease slightly (2.2%), there are areas of the United States where heroin is readily available and current use would be higher. Heroin is particularly dangerous because it is purer than in the past and also frequently laced with fentanyl, a potent painkiller. The ready availability for sale and consumption of opioid prescription pain medications has led to a nationwide "opioid crisis," which has affected people of all ages but particularly older adolescents and young adults. Opioid overdose is becoming a leading cause of death for people in these age groups (USDHHS, 2016). Evidence suggests that use of prescription pain medications can lead to heroin use (USDHHS, 2016), and many adolescents become addicted through indiscriminate pain management of a musculoskeletal or other injury. Contributing factors to this epidemic include overprescribing, prescribing higher doses than are needed to control the pain, and lack of prescription monitoring, allowing patients to obtain prescriptions from multiple pharmacies (USDHHS, 2016).

Substance use is a precursor to abuse, which emphasizes the need for health care providers to be alert for and screen individuals for its presence. Identifying adolescent substance users or abusers requires a careful nursing assessment that is conducted in an accepting manner (Boxes 21-10 and 21-11) and referral for appropriate management. The AAP (2014) recommends individuals be screened for substance use at every well visit during adolescence using the CRAFFT mnemonic.

Box 21-10

Major Signs of Substance Abuse

Depending on the Substance Used, the Signs Can Include the Following:

- Agitation
- Altered sleep
- Appetite loss
- Blackouts
- Depression
- Diarrhea
- Distorted perception
- Drowsiness/lethargy
- Dry mucous membranes
- Euphoria
- Hallucinations
- Inability to concentrate or solve problems
- Inability to perform regular work or social activities
- Memory loss
- Nausea
- Poor coordination
- Respiratory depression
- Unintentional injuries
- Weight loss
- Withdrawal

Box 21-11

CRAFFT: Adolescent Substance Abuse Screening Test

A brief screening test for adolescent substance abuse developed by the Center for Adolescent Substance Abuse Research at the Boston Children's Hospital uses the acronym CRAFFT to guide health care providers when they are interviewing adolescents about substance abuse:

C—Have you ever ridden in a CAR driven by someone, including yourself, who was "high" or had been using alcohol or drugs?

R—Do you ever use alcohol or drugs to RELAX, feel better about yourself, or fit in?

A—Do you ever use alcohol or drugs when you are by yourself, ALONE?

F—Do you ever FORGET things you did while using alcohol or drugs?

F—Does your family or do your FRIENDS ever tell you that you should cut down on your drinking or drug use?

T—Have you gotten into TROUBLE while you were using alcohol or drugs?

Two or more affirmative answers suggest a significant problem and warrant referral and follow-up.

Reprinted with permission from the Center for Adolescent Substance Abuse Research, Boston Children's Hospital ©2009.

Substance use and abuse prevention and management requires a

community as well as an individual approach. For adolescent problem drinkers, Alcoholics Anonymous has pamphlets and other resources, including meetings, for young people who are ready to begin recovery. In response to the opioid epidemic, communities have supplied school, police, and emergency personnel with naloxone (Narcan) to be used for treatment of overdoses. Many states are approving legislation directed toward limiting the duration of individual pain medications, instituting prescription monitoring programs, and safe disposal of unused medication. Insurance companies are allowing patients to choose to receive fewer doses than prescribed and are increasing coverage for substance abuse treatment. Nurses need to be advocates for these and other approaches to this serious issue.

Tobacco Use

Although 9.2% of adolescents report beginning smoking at a young age, 5.6% identify themselves as currently frequent smokers. Smoking is more prevalent in white males and females than in black or Hispanic populations (CDC, 2014b). Another form of tobacco use is use of smokeless tobacco, such as chewing tobacco, snuff, or dip. Recently, adolescents have begun using electronic cigarettes (e-cigarettes, vaping). Electronic cigarettes, which are battery operated, vaporize liquid for inhalation through an appliance that resembles a cigarette; there is no smoke involved (Johnson & Pennington, 2015). Flavored liquid in cartridges, either with or without nicotine, is attractive and available to adolescents. Because of the newness of this trend, there is little evidence to determine whether e-cigarette use will contribute to tobacco use. Several states, however, have enacted legislation to regulate the sale and distribution of e-cigarettes to children (Johnson & Pennington, 2015). Adolescents begin using tobacco for a variety of reasons, including wanting to appear older or wanting to imitate their friends, adult role models, or media images. Advertising by the tobacco industry directed at adolescents has been shown to encourage adolescent smoking.

The nurse's primary prevention focus is on keeping nonsmokers

from starting smoking and helping smokers to stop. Nurses can become actively involved in smoking-prevention programs through school districts or in the community. The Agency for Healthcare Research and Quality (2012) has published *Five Major Steps to Intervention (the "5 A's")*, which can organize an approach to smokers who are considering quitting soon. These include:

- *Ask* about tobacco use.
- *Advise* to quit.
- *Assess* willingness to attempt quitting.
- *Assist* in quit attempt.
- *Arrange* for follow-up.

Determinants of Health

Social Factors and Environment

School

Middle school or junior high and high school bring new social experiences, introducing the adolescent to changing classes, multiple teachers and teaching styles, variable class schedules, homework load, and a variety of peer influences. School populations may be significantly larger than the child has experienced previously, and making and solidifying new friendships may be more difficult. Yet, despite these challenges, these school settings also provide meaningful in-school and after-school learning, peer contact, intellectual stimulation, and social or volunteer community service activities (Figure 21-6).

FIGURE 21-6 Adolescents participate in school-sponsored community service.

Schools and peers, as opposed to home and parents, become the primary setting through which expectations are shared and standards

communicated. During health-promotion visits, nurses ask adolescents about school and their friends and how they are doing with both. The nurse can also monitor adolescents as they prepare for and make the transition to their next social arena and role, whether it is college, vocational training, the military, or another career choice.

Culture and Ethnicity

Cultural and ethnic influences operate throughout childhood and continue into adolescence. The primary difference in adolescence is that teens question, modify, or reject these influences, exchanging them for those of their peers or of the dominant cultural group. First-generation adolescents of immigrant parents have to negotiate two cultures, languages, and sets of expectations. These adolescents often live a double life that might result in increased stress. Adolescents from minority groups, such as black Americans, Hispanics, Asian Americans, Native Americans, Russian Americans, or Arab Americans, might experience discrimination and rejection if they try to fit in to the dominant adolescent culture, which is often middle class, white, and Protestant. Advertising is directed to middle-class or affluent teens, not the economically depressed, and media images might not include attractive ethnic-looking models. Adolescents from different cultures might experience additional stress when their attempts to fit in to the dominant culture are contrary to the values and beliefs of their own culture.

The growing ethnic diversity in the adolescent population influences how adolescent health will be approached. For example, the US Census Bureau reports that the Asian population increased by 43% between 2000 and 2010, growing faster than any other major race group during that period (Humes et al., 2011) (Box 21-12: Diversity Awareness). With fast growth in the numbers of Hispanic and Asian American youth, cultural awareness of health care needs and the highlighted attention to health disparities and academic outcomes, especially among adolescents from racial minorities and ethnic groups, are required. Nurses need to recognize the additional stresses experienced by adolescents and assess them for those stresses as they

wrestle not only with their own identities but also with their cultural identities.

Box 21-12

Diversity Awareness

Barriers to Recruiting Chinese American Adolescents for Future Development of HIV Interventional Programs: A Lesson Learned

It has been suggested that there is an imperative need to deliver culturally sensitive programs for HIV/AIDS prevention. To oppose health disparities in the United States, recruiting participants with an ethnic minority background in health care research is essential. Chinese Americans comprise the largest ethnic group of Asian Americans and have rarely been separated from a combination of various Asian American populations to address issues related to HIV/AIDS prevention. Given that there are many distinct and separate cultures within the Asian American community, this misclassification makes Chinese Americans an underrepresented population in HIV/AIDS research and has resulted in limited public awareness and deprived this population of HIV/AIDS preventive services. It is important for nurses to know about the recruitment strategies or challenges specific to enrolling Chinese Americans so as to have capabilities to efficiently approach Chinese American adolescents and deliver culturally sensitive HIV/AIDS prevention programs.

The purpose of this article was to report identified barriers and challenges experienced in the process of recruiting Chinese American adolescents for a cross-sectional HIV/AIDS-related study. The sexual topic, a taboo in Chinese culture, was the major barrier to recruiting Chinese American adolescents. Barriers to recruitment were also found related to unawareness and denial of HIV/AIDS risks, authoritarian parenting style in Chinese culture, and the required

informed consents. The most successful recruitment strategy was found to be associated with the assistance of Chinese American adolescent participants. Providing educational programs targeting Chinese American parents and community leaders to enhance their awareness of the risks and to improve parent-child communication regarding sex-related issues was suggested as the first step to successfully approach and recruit Chinese American adolescents for an HIV/AIDS-related prevention program or research.

From Lee, Y. H., Salman, A., & Wang, F. (2012). Recruiting Chinese-American adolescents to HIV/AIDS related research: A lesson learned from a cross-sectional study. *Applied Nursing Research, 24*(1):40–46.

Levels of Policy Making and Health

Many laws and regulations are aimed at adolescents and deal with the minimum age at which they can assume adult responsibilities and decision-making. The rationale for these restrictions is that adolescents, although capable, lack the experience, perspective, and judgment to recognize and avoid choices that might be detrimental to them, so they require protection. A question raised frequently when minimum age is considered is whether strict age criteria are appropriate for any adolescent, particularly because development is variable and experiences are diverse.

The restrictions that have recently been questioned most strongly deal with issues related to sexual activity. The US Supreme Court affirmed the right of all individuals to have equal access to contraceptive service, regardless of age or marital status. However, variations occur from state to state, and the nurse must be aware of legal age determinants, as well as variations in definitions of **emancipated minors.**

The emancipated minor provision of certain laws recognizes that some adolescents become independent from their families at an early age and assume adult responsibilities. An emancipated minor is an adolescent who has not reached the standard legal age for certain activities, such as consenting to marriage or seeking certain kinds of health or illness care, but who is permitted to accept full responsibility

for these decisions because the individual is economically and emotionally separate from the family.

Most often confidentiality is the more important issue for adolescents. The nurse can assure them that information shared will be kept confidential unless the teens pose a risk to themselves or others, or state or public health reporting mandates that the information be shared. For example, abuse must be reported, STIs need to be reported, and some states require adolescent sexual activity to be reported if an age difference of 3 years or more exists between the sexual partners.

Nurses need to familiarize themselves with the legal rights of adolescents in their state and the resources available in their community.

Economics

Identification with peers, the essence of self-image during adolescence, includes dressing alike, having similar possessions, and doing similar activities, all of which require economic resources. This can cause a major conflict between parents and adolescents. Parents may think that they should have the power to decide how their adolescent spends money. Adolescents may believe, just as strongly, that they know the best ways to allocate resources and determine the amount of money they need.

Ideally, parents and adolescents should negotiate economic questions, with the parents becoming less controlling as the teen gains more experience and expertise in these matters. However, the family with limited economic resources has fewer choices, and adolescents from these families may feel trapped by their circumstance. Poverty is particularly hard on children, and as they become adolescents, they often develop a fatalistic view of life.

Some adolescents seek employment to earn their own money and have control over it. Others work because their families need the income. It is important for the nurse to assess the economic resources of each adolescent's family and work within them when partnering with the adolescent in health care planning.

Health Services/Delivery System

Many health care resources are available to the adolescent. Teens can continue to see their child health care providers in a pediatric center as they did as younger children, but this setting is usually rejected because of the young-child atmosphere.

School-based clinics are frequently available in junior high and high school, and adolescent-focused clinics are available in many communities through both public and private agencies. Each of these clinics serves only adolescents, and the staff is oriented to the needs of this age group. Adolescents frequently have a stronger sense of comfort in these settings than in those in which young children or adults are also served.

Adolescents can also make use of services such as family planning clinics. These settings may designate certain days and hours for teens, whereas other facilities integrate them into the adult-oriented protocols. The pregnant adolescent typically finds prenatal care in an adult-focused setting, although more adolescent-specific programs are being developed. The physical needs of pregnant adolescents may be the same as those of the pregnant adult, but the psychosocial needs are different and should be approached by a professional who has comprehensive knowledge of their development and responses to stress.

The adolescent is a rapidly changing individual. The nurse who works in an adolescent-focused practice is well prepared in adolescent health-promotion strategies. The nurse should have a thorough understanding of adolescent physical and psychosocial growth and development and recognize each teen as a person.

Adolescents not only tend to be fearful about procedures or possible diagnoses but also need to stay in control of the situation. These conflicting feelings can be difficult to manage simultaneously. By establishing the adolescent as a partner with the health care providers in promoting good health and screening the adolescent for health risks, the nurse facilitates the adolescent's sense of control (Box 21-13).

Box 21-13

HEADSSS Assessment

The HEADSSS assessment provides a mnemonic that guides health care providers through an adolescent's psychosocial assessment. Responses should be interpreted as those that are indicators of strengths or protection from risk and those that are indicators of risky behavior or situations.

From Klein, D., Goldenring, J., & Adelman, W. (2014). HEADSSS 3.0: The psychosocial interview for adolescents updated for a new century fueled by media. http://contemporarypediatrics.modernmedicine.com/contemporary-pediatrics/content/tags/adolescent-medicine/heeadsss-30-psychosocial-interview-adolesce?page=full.

The adolescent's questions should be answered thoroughly and honestly. In many instances the adolescent is hesitant to voice concerns, so information is offered even when questions are not asked. An effective indirect approach to learning about adolescent concerns, especially about potentially embarrassing or stressful topics, is to say "Many teenagers ask me about [a topic]. Have you ever thought about this?" or "A lot of young people want to know about [a topic]."

Direct questions are also important, even about sensitive topics:

“Have you ever thought about suicide?” “Are you depressed?” “Are you sexually active?” “Do you use birth control and/or protection?” However, asking first about friends and the adolescent's feelings about them may be a good lead-in approach: “Are any of your friends doing drugs?” “How do you feel about it?” Vague or circuitous questions may be interpreted as a sign of discomfort or lack of understanding and may cause the adolescent to be equally vague when responding.

Correct anatomical terms and descriptions of laboratory tests, disease processes, and possible outcomes are essential components in treating adolescents as individuals who are capable of being responsible for their own bodies.

Nursing Application

Adolescence is a period of rapid growth and development with changes occurring physically and psychosocially. Nurses play a pivotal role in influencing health-promotion, preventive-screening, and disease-prevention activities. The primary responsibility for the nurse dealing with the important period known as the transition from childhood to adulthood is to provide education about some of the expected changes and how to deal with them.

Primary prevention methods are effective when the nurse is able to partner with the adolescent in recognizing his or her health needs. Treating the teen in a respectful manner enables the teen to assume more responsibility. Nurses must remain sensitive to the changes the adolescent is encountering and understand the need for guided independence.

Some important health-education topics for the adolescent population include proper nutrition, exercise, teen pregnancy (National Campaign, 2015), and protection against STIs (CDC, 2014a). Teens are taught about the significance of their lifestyle choices with regard to future health. Drug and alcohol use, injury prevention, violence, and tobacco use are all behaviors that are known to contribute to illness and death among teens. Nurses use educational tools that appeal to the age group by conducting Internet searches for resources. Teens are able to relate to Internet resources, celebrities, and social media sites. Peers have the greatest influence on teenagers.

Nurses need to educate teens in partnership with their parents about the fact that unintentional injuries are the leading cause of death in the adolescent population. Nurses should reinforce research regarding distracted driving, seat belt use, and texting, adjusting the radio, and listening to loud music while driving.

Adolescent girls are educated about breast self-examinations, cervical cancer, and human papilloma virus. Adolescent males are educated about testicular self-examination. Both sexes are encouraged to undergo physical examinations and follow the recommended

vaccination schedule.

Various screenings are used by the nurse as a secondary prevention measure for the adolescent. Scoliosis screening is conducted in prepubertal and pubertal adolescents because early identification and treatment is important to prevent long-term disability or disfigurement. Nurses also screen adolescents for hypertension, eating disorders, type 2 diabetes, pregnancy, and STIs.

Adolescents respond better when they feel that they are regarded as young adults and a partner in their health-promotion efforts. The nurse needs to become skilled at discussing difficult or embarrassing topics with teenagers. It is essential that adolescents feel that they are treated with respect and regarded as an individual.

Case Study

Drug-Facilitated Sexual Assault: Jessica

Sexual assault includes any type of sexual activity to which an individual does not agree. Because of the effects of some drugs, commonly called date rape drugs, victims may be physically helpless, unable to refuse, or even unable to remember what happened.

Jessica, a 16-year-old high school sophomore, expresses concern to the school nurse that she knows someone who might have had sex "without knowing it." How can the nurse answer these common questions?

Reflective Questions

- What are date rape drugs and how can a person be unaware that such a drug has been ingested?
- What can you do to protect yourself?
- What do you do if you think you have been sexually assaulted?
- What can you do when someone you care about has been sexually

assaulted?

Care Plan

Drug-Facilitated Sexual Assault: Jessica

***NURSING DIAGNOSIS: Risk of powerlessness related to suspected rape/rape trauma syndrome**

Definition

At risk of perceived lack of control over a situation and/or one's ability to significantly affect an outcome

Risk Factors

- Suspected date rape/rape trauma syndrome
- Acute injury (rape)
- Deficient knowledge
- Disturbed body image
- Situational low self-esteem

Expected Outcomes

- Acknowledges personal strength
- Perceived control
- Perceived resources
- Participation in health care decisions
- Increase healthy lifestyle choices

Goal: Increase individual's sense of power over potential/actual situation for self/others.

Interventions

- Active listening
- Risk identification
- Health care information exchange
- Support system enhancement
- Rape trauma treatment and referral
- Decision-making support
- Health education

Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Adolescence is a period of rapid change, when the integration of family, peer, educational, social, cultural, and community experiences begins to take form in the teen's sense of self. Many view adolescence as a construction site in its early stages. Onlookers assume that eventually a recognizable structure will emerge but have no idea what that structure will be. Although many parents, teachers, and health care providers feel that hard hats and steel-reinforced shoes are needed, each is better equipped with an understanding of and respect for the adolescent's developmental struggles with physical and cognitive changes, autonomy, body image, peer relations, and identity. The goal, after all, is for the teen to emerge in young adulthood with a healthy body, mind, and spirit.

Young Adult

Elizabeth Connelly Kudzma

OBJECTIVES

After completing this chapter, the reader will be able to:

- Analyze specific health recommendations for the young adult.
- Identify attitudes, behaviors, and habits that compose the lifestyles of young adults.
- Define tasks that are consistent with adult development.
- Describe the nurse's role in reducing the rate of unintentional pregnancies in young adult women.
- Determine occupational hazards that interfere with the young adult's welfare.
- Evaluate strategies that the nurse can use to reduce the risks associated with young adult behaviors.
- Analyze occupational, cultural, and ethnic risk factors that may affect young adults.
- Delineate nursing roles in preventive intervention for healthy young adults in home and community environments.
- Discuss proposed suggestions for preconceptional care.

KEY TERMS

Achievement-oriented stress

Aerobic exercise

Basal metabolic rate

Binge drinking
Breast self-examination
Congenital defects
Coronary artery disease
Fetal neural tube defects
Genetic impairments
Hepatitis B
Human immunodeficiency virus
Human papilloma virus
Hypertension
Infertility
Intimacy versus isolation
Maternal mortality rate
Metabolic syndrome
Orchitis
Papanicolaou (Pap) smear
Postconventional level of moral reasoning
Sexual consent
Stress
Sun protection factor
Testicular self-examination

Think About It

Using Private Information in Shared Living Arrangements

Young adults in communal living arrangements (college dormitories, the military) are often placed with other individuals who have different cultural,

language, or other values. The use of cell phones and computers with video and audio recording capabilities has opened the possibility that private behavior may be recorded without consent and then may be shared through a form of social networking (Facebook, Twitter, instant messaging, apps, and other shared computer sites). There are even instances where recording has occurred in classrooms without the permission of the instructor or others in the class.

These situations are expected to become more prevalent.

- What are the implications of this for violation of privacy for individuals and even groups (e.g., military, fraternities, sororities)?
- What are the legal implications? Some states have laws against unauthorized recording.
- How might unauthorized recording alter classroom, dormitory, and communal living dynamics?

The young adult period encompasses the ages from 18 to 35 years, a time that spans the end of adolescence to the beginning of middle adulthood. Formal education beyond high school to college and graduate school, as well as military experience, and the major milestones of marriage and beginning a family may be included in this phase of development. The major task accomplished in this period is preparing for and assuming full adult responsibilities, rights, and privileges. This is a potentially difficult period as young adults are not totally independent and are learning to separate from the home and their parents (Neinstein, 2013).

Biology and Genomics

The young adult period is a time of many physical and emotional changes and is an opportunity for learning by experience and experimentation (Box 22-1: Quality and Safety Scenario). Young adulthood is characterized by greater complexity of thinking, further organization of emotional and cognitive development, and decision-making based on the impact on others and future consequences. All phases of young adult development garner considerable interest. Judging by the increase in the number of books on self-development, more young adults are exploring topics in holistic healing and spiritual health and development. Health behaviors, safety practices, diet, exercise, weight control, sexuality, and addictions are widely discussed topics. Preventive health concerns for young adults can be separated into two categories: developing behaviors that promote a healthy lifestyle and decreasing the incidence of accidents, injuries, and acts of violence. In *Healthy People 2020*, it is stated that 72% of all deaths among children and young adults are due to injuries from four causes: motor vehicle crashes (30%), all other unintentional injuries (15%), homicide (15%), and suicide (12%) (US Department of Health and Human Services [USDHHS], 2015).

Box 22-1

Quality/Safety Scenario

Topic: Examining Problematic College Drinking Behaviors in Young Adults

A study of 211 college students indicates that 63% of female and 83% of male college-aged students (mean age 20.7 years) engaged in binge drinking. Associated with these intermittent excessive drinking "binges" were various disordered and unhealthy weight-reducing behaviors (skipping meals, fasting, using diet pills, and self-induced

vomiting) (Kelly-Weeder, 2011).

You are the clinic director and nurse at a small liberal arts college. Mary, a 19-year-old first-year student, has generally been a good student, easily making the adjustment to living away from home during her first 2 months in the dormitory. She comes to you to talk about an episode that occurred the previous weekend and that frightened her. On Saturday night, she was at a party at a private residence in a rural, wooded setting away from the campus. She remembers consuming five or six alcoholic drinks; however, any memory after midnight is missing. She woke up in a fellow female student's dormitory room without any memory of leaving the party or returning to the dormitory. She was able to piece together information from her friends, who told her that she had consumed at least nine alcoholic drinks that night and that she had left the party with others who were returning to the dormitory, but they were not the friends with whom she had been seen all evening. She is concerned that she may have been drugged or that she may be having memory lapses. Assessment of her previous alcohol use reveals that she can recount at least four occasions during which she drank more than seven drinks at a party or family gathering. She describes her family as "social drinkers." On days that she anticipates drinking, she restricts her caloric intake. Last June, she was involved in a minor car accident that might have been related to her consumption of at least three drinks that afternoon. The road to this rural college has two road side shrines dedicated to students who have died in automobile crashes near the college. To further analyze Mary's situation, you formulate the following questions:

- Do you think that Mary has a problem with drinking? Would you classify her as a binge drinker? How do you clarify what she values?
- Is Mary engaging in risky behavior especially if she drives while drinking?
- What kind of physical assessment might assist you in making a determination that Mary has a drinking problem?
- What kinds of preventive educational programs could you advise?

- What kinds of monitoring and follow-up mechanisms might assist Mary in keeping her safe and in a treatment plan?

From Kelly-Weeder, S. (2011). Binge drinking and disordered eating in college students. *Journal of the American Academy of Nurse Practitioners, 23*(1), 33–41; Quality and Safety Education for Nurses Institute. (2012). http://www.qsen.org; Institute of Medicine. (2003). Health professions education: A bridge to quality. http://www.nationalacademies.org/hmd/Reports/2003/Health-Professions-Education-A-Bridge-to-Quality.aspx

In 2014, approximately 20.5% of the American population was composed of adults aged 20 to 34 (US Census Bureau, 2014). The young adult population aged 18 to 24 years is projected to be approximately 9.13% of the general population by 2020 and 8.34% by 2035. The percentage of young adults aged 20 to 24 years is expected to decline to 8% in 2060 (US Census Bureau, 2014). A decline in this age group is influenced by birth rates, and the Centers for Disease Control and Prevention (CDC, 2015a) reported that the birth rate per 1000 women of all ages in 2013 was 12.4; this rate has been dropping since 1990, when it was more than 16.7 live births per 1000. Therefore the US Census Bureau projects the young adult population will grow more slowly in future decades as fertility rates decline, and the projections illustrate modest declines in immigration. Health-promotion efforts are particularly important for young adults because health teaching for this age group has the significant potential to directly influence subsequent generations (Box 22-2: Healthy People 2020).

Box 22-2

Healthy People 2020

Selected National Health-Promotion and Disease-Prevention Objectives for the Young Adult

- Increase the proportion of adults who engage in regular aerobic activity of moderate intensity. (In 2013, 49.9% of adults performed

the recommended amount of physical activity [150 minutes per week], and the target is 47.9%.)

- Increase the proportion of adults who are at a healthy weight. (From 2009 through 2012, 29.5% of adults aged 20 years or older were at a healthy weight, and the target is 33.9%.)

- Reduce the proportion of adults who are obese. (From 2009 through 2012, 35.3% of adults aged 20 years or older were considered obese, and the target is 30.5%.)

- Reduce the proportion of adults using any illicit drug during the preceding 30 days. (Illicit drug use in adults aged 18 years or older in 2013 was 9.4%, and the target is 7.1%.)

- Reduce the proportion of college students engaging in binge drinking of alcoholic beverages during the past 2 weeks. (In 2012, 37.1% of college students reported binge drinking in the past 2 weeks, and the target is 36.0%.)

- Increase the proportion of females at risk of unintended pregnancy or their partners who used contraception in the most recent sexual intercourse. (From 2011 through 2013, 83% of sexually active females or their partners used contraception, and the target is 91.6%.)

- Increase the proportion of adults aged 18 years or older with major depressive episodes who receive treatment. (In 2013, 68.6% of adults with diagnosed depression received treatment, and the target is 75.9%.)

- Reduce deaths caused by motor vehicle crashes. (In 2012, 10.9 deaths per 100,000 population occurred, and the target is 12.4.)

- Increase the number of states that have adopted a graduated driver licensing model law. (In 2009, 32 states had adopted graduate driver licensing, and the target is 51 states, including the District of

Columbia. There is difficulty in measuring the various components of state laws for graduated licensing.)

- Increase the proportion of motorcycle operators and passengers using helmets. (In 2013, the baseline was 60%, and the target is 73.7%.)

- Reduce sports and recreation injuries. (In 2013, there were 45.6 medically consulted injuries per 1000 population, and the target is 41.9 injuries per 1000 population.)

- Reduce firearm-related deaths. (In 2012, there were 10.5 firearm-related deaths per 100,000 population, and the target is 9.3 per 100,000 population.)

- Increase the proportion of persons with a usual primary care provider. (In 2011, 77% of all individuals had a usual source of health care, and the target is 83.9%, a 10% increase.)

- Increase the proportion of women who receive early and adequate prenatal care. (In 2007, 70.5% received early and adequate prenatal care, and the target is 77.6%.)

- Increase the proportion of adults aged 20 years or older who are aware of the signs of heart attack and the importance of accessing rapid emergency care. (In 2008, 37% of adults were aware of the signs of heart attack and the need for and access to emergency care; the target is 40.9%.)

- Increase the proportion of adults aged 18 years or older who have had their cholesterol level measured in the last 5 years. (In 2008, 74.6% of adults aged 18 years or older had their blood cholesterol level checked, and the target is 82%.)

- Increase the proportion of adults aged 18 years or older who follow protective measures that may reduce the risk of skin cancer. (In 2010, 70% of this population used protective measures, and the

target is 73.7%.)

From US Department of Health and Human Services. (2015). *Healthy People 2020.* Washington, DC: US Government Printing Office.

Young adulthood is generally the healthiest time of life. Physical growth is mostly complete by the age of 20 years; most concerns related to physiological development are focused on ensuring optimal functioning of body systems. The young adult's physical abilities are in peak condition, and compensatory mechanisms operate optimally during illness to provide minimal disruption in health patterns. Nursing goals for individuals of this age group are oriented toward prolonging this period of optimal physical energy; developing the mental, emotional, spiritual, and social potential; encouraging proper health habits; anticipating and screening individuals for the onset of chronic disease and therefore being able to treat it at an early stage; and treating disease when appropriate.

Full adult stature in men is reached at approximately age 21 years; in women, full growth occurs earlier, typically by age 17 years. Optimal muscle strength occurs from age 25 years to age 30 years, and then gradually declines by approximately 10% from age 30 years to age 60 years. Manual dexterity peaks in young adulthood and begins to decline in the mid-30s.

Women have greater longevity than men. Women are considered biologically stronger than men, outlive men, and naturally outnumber men. On average, in the United States women live 5 years longer than men (CDC, 2013a). This statistic may be a result in part of female genetic composition or men's greater exposure to environmental and occupational hazards. Men also seek health care services less frequently than women. Women generally seek preventive care more often than men. Although some of this reflects the inclusion of multiple prenatal visits, it also supports better health practices.

A classic public health indicator of a nation's health resources and services that involves young adults is the **maternal mortality rate**. In 1980 the rate was 9.2 per 100,000 live births, then dropped to 6.6 per 100,000 live births in 1987 and rose to 8.9 per 100,000 live births in

2002. In 2007 the maternal mortality rate was much higher, 12.7 per 100,000 live births (USDHHS, 2015), reflecting inclusion of pregnancy status as a separate item on death certificates in some states. *Healthy People 2020* (USDHHS, 2015) sets a target goal of 11.4 maternal deaths per 100,000 live births, but to reach this goal there is a need for much more national and statewide action to identify gaps in health disparities, early prevention, treatment, and research.

Gordon's Functional Health Patterns

Health Perception–Health Management Pattern

Because excellent physical health is frequently taken for granted, concern about health and well-being is relatively low in individuals in their 20s but begins to increase in individuals in their 30s. Monitoring of specific health parameters is both necessary and appropriate to determine health needs and incipient problems. After the mid-30s, an increased sense of the finiteness of life develops with limitations imposed by work choices, well-being, monetary resources, and the deterioration of physical abilities. Specific health care management in the young adult age span is generally split into health care management for various age groups according to the preventive services that are required.

The assumption that all adults should have an annual physical examination has been supplanted by increased scientifically based information about health screening measures. Screening services provided in a health-monitoring program need to meet effectiveness criteria. Evidence-based practice uses best practices' information for clinical decisions instead of intuition and unmethodical past clinical experience and, as such, forms a basis for the current recommended standard of care. Evidence-based approaches will ultimately determine which screening measures are best supported by scientific data (randomized controlled treatment studies), reduce regional variations in the use of diagnostic and therapeutic modalities, and close the gap between practice and research (Melnyk & Fineout-Overholt, 2014).

Behavioral Health History

A health history inclusive of behavior is particularly important for young adults. This type of history focuses on risk factors for unintentional injuries, such as accidents, seat belt use, and alcohol consumption, which are major causes of death and disability in this

age group. The safety focus of nursing health promotion for the younger adult takes different forms, from the simple—monitoring helmet and seat belt use—to more complex concerns—threats such as bioterrorism and globally spreading infections (USDHHS, 2015). Figure 22-1 lists questions and content that may be appropriately included in a health history for young adults focusing on probable age-specific behaviors.

Well Young Adult Behavioral Health History Content

Sociodemographic content and questions:

What organizations (community, church, lodge, social, professional, etc.) are you involved in?_____

_____

How would you describe your community?_____

_____

Hobbies, skills, interests, and recreational activities?_____

Military service? No_____ Yes_____ From ____ to_____

Overseas assignment? No_____ Yes_____

Close friends or immediate family members who have died within the past two years?_____

_____

Names and addresses of relatives or close friends in the area._____

_____

_____

Marital status: S M D W Length of time _____

Environmental content and questions:

Do you live alone? No_____ Yes_____

When did you last move?_____

Describe your living situation. _____

Number of years of education completed:_____

Elementary?_____ High school?_____ College?_____

Occupation?_____ Employer?_____

How long have you worked for this employer?_____

Are you satisfied with your work situation? No_____ Yes_____

Do you consider your work risky or dangerous? No_____ Yes_____

Is your work stressful? No_____ Yes_____

Over the past two weeks, have you felt depressed or hopeless? No_____ Yes_____

Biophysical content questions:

Have you smoked cigarettes? No_____ Yes_____

How much? Less than ½ pack per day? About one pack per day? More than 1½ packs per day?

Are you smoking now? No_____ Yes_____ Length of time smoking?_____

Have you ever smoked cigars or a pipe? No_____ Yes_____

If yes, how long?_____ Do you smoke cigars or a pipe now? No_____ Yes_____

Do you drink alcohol (wine, beer, or whiskey)? No_____ Yes_____

If you do, how much each day on the average?_____ Each week?_____

Do you consume large amounts occasionally (binge drinking)? No_____ Yes_____

Have you been drunk on work days? No_____ Yes_____

Have you had alcoholic drinks in the morning sometime in the past year? No_____ Yes_____

How much coffee, tea, or cola do you drink?_____

Do you use seat or lap belts? No_____ Yes_____

What type of exercise do you do each week? Describe type and amount. _____

_____

Are you satisfied with your weight? No_____ Yes_____ Body image? No_____ Yes_____

Do you use a bicycle or motorcycle helmet? No_____ Yes_____ Helmet and pads while rollerblading? No_____ Yes_____

How much sleep do you usually get each night?_____

Meals: Do you generally eat: three regular meals per day? two meals per day? irregular meals?

Are you sexually active? No_____ Yes_____

If so, are you aware of the risks of sexually transmitted diseases? No_____ Yes_____

FIGURE 22-1 Common well young adult behavioral health history content. (From Somers, A. R., & Breslow, L. [1979]. Lifetime health monitoring program. *Nurse Practitioner, 4*[40], 50–54; US Preventive Services Task Force. [2015]. *Published recommendations.* Rockville, MD: Agency for Healthcare Research and Quality.)

Preventive Care

The basic goals of preventive care are to maximize the period of optimal health status and detect incipient health problems. At age 18 years (approximately the time of graduation from high school), a full health appraisal is recommended. Table 22-1 illustrates examples of preventive care that is important during the young adult period, along with the recommended frequency of screening. As a common expectation, the recommendation for most areas is a repeated health history and visit at approximately 2-year intervals. Appropriate intervention is directed toward correcting health issues through history assessment and counseling about avoidance of adverse health behaviors. Subsequent counseling sessions focus on rechecking and updating information gathered in earlier meetings. Young adults are less likely to undergo well visits and ambulatory care visits, leading to lower experience with preventive services (Hing & Albert, 2016; National Adolescent and Young Adult Health Information Center, 2012; Neinstein, 2013).

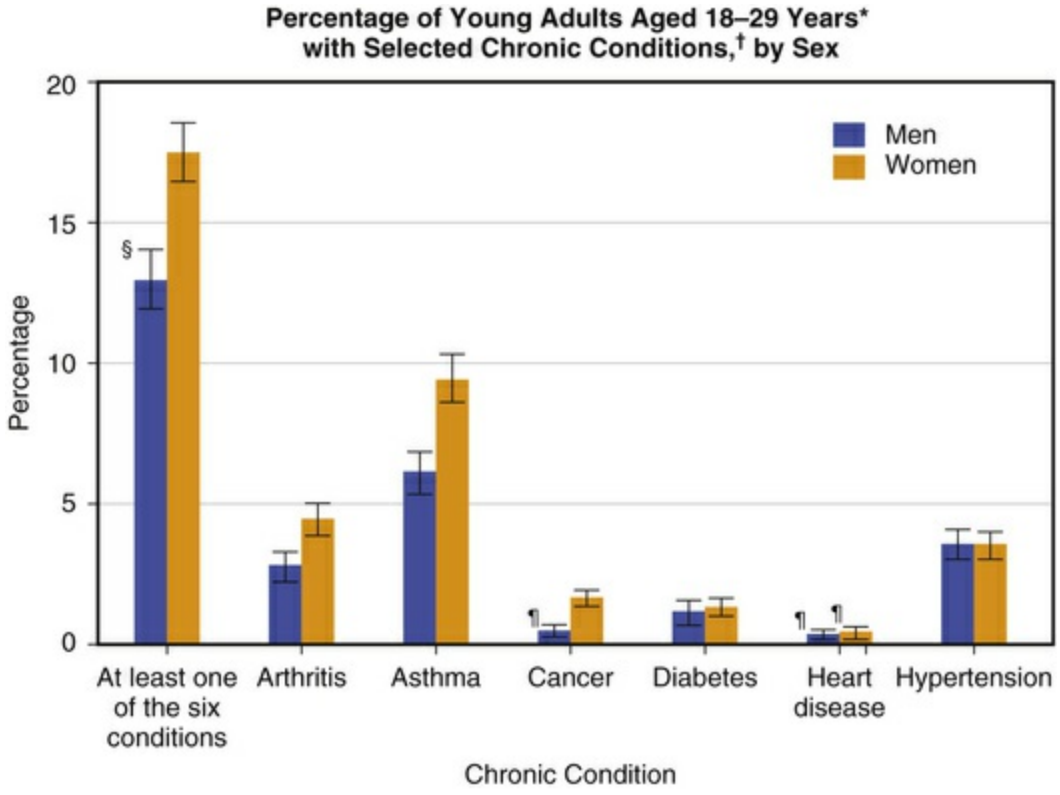
TABLE 22-1

Young Adult Preventive Health Monitoring (Examples)

Health Issue	AGE 18–26 YR	
	Intervention	Frequency
Tobacco screening and counseling	History and counseling	Each visit
Obesity/nutrition/body mass index	History, weight, and counseling	Each visit
Alcohol screening and counseling	History and counseling	At least once
Accidental injury, lap and shoulder belts, bicycle or motorcycle helmets, smoke detectors, safe firearm use	History and counseling	At least once
Unintended pregnancy	Counseling	At least once
Contraception	Counseling	Individually determined
Illegal drug use screening	History and counseling	At least once
Regular physical activity	History and counseling	At least once
Hypertension/blood pressure	Blood pressure measurement	Every 2 yr
Tetanus, diphtheria, pertussis	Tdap booster vaccine	Once if 10 yr since last one

Hepatitis B	Immunization	If not immunized
Diabetes, proteinuria, bacteriuria	Urinalysis	Once
Cholesterol levels	Serum cholesterol level determination, triglyceride level	Once
Cervical dysplasia	Gynecological examination; Papanicolaou smear	Every 2 yr, start at age 21 yr, or when sexually active
STI prevention	Counseling—offer HPV vaccine	Individually determined
Chlamydia (women)	*Chlamydia* screen	At gynecological examination if sexually active
Gonorrhea	Vaginal culture	At gynecological examination if sexually active
Influenza	Seasonal flu vaccine	Each year

The ages differ in different publications and sources.



HPV, human papilloma virus; *STI*, sexually transmitted infection.

Modified from National Adolescent and Young Adult Health Information Center. (2012). Clinical preventive services for young adults. http://nahic.ucsf.edu/clinical-preventiveservices-for-young-adults/; US National Library of Medicine. (2015). Health screening for women/men ages 18-39. https://medlineplus.gov/ency/article/007462.htm

A physical examination includes measurements of height, weight, body mass index (BMI), and blood pressure, and blood tests, with an emphasis on the need to avoid inactivity and obesity, which are risk factors for many health problems. The US Preventive Services Task Force (USPSTF, 2015) currently recommends against teaching **breast self-examination**, and concludes that the current evidence is insufficient to assess the additional benefits and harm of clinical breast examination beyond screening mammography for women aged 40 years or older. Screening for cervical cancer is strongly recommended in women who have been sexually active (**Papanicolaou [Pap] smear**). **Testicular self-examination** may be taught to men in this age group, although there is little evidence to assess the accuracy, benefits, or effectiveness (USPSTF, 2015) because early testicular cancers often present as benign inflammations (epididymitis or testicular trauma).

The typical young adult health examination also looks for signs of chronic disease. The most common chronic diseases reported by young adults are asthma, arthritis (including rheumatic diseases such

as lupus and fibromyalgia), and hypertension (Figure 22-2). Although the percentage of young adults reporting chronic disease is small, more women than men (17.4% versus 12.9%) reported having at least one of the six most highly selected young adult chronic disease conditions (arthritis, asthma, cancer, diabetes, heart disease, and hypertension) (CDC, 2009). Some evidence suggests that young adults do not follow the guidelines for prevention of these common chronic diseases, which are the most disabling and costly (McDaniel & Belury, 2012; Neinstein, 2013).

* Overall respondents: 6898 men and 8532 women

† Estimates are based on household interviews with a sample of the civilian, noninstitutionalized, adult U.S. population. The prevalence of diagnosed chronic conditions was determined by asking respondents if a doctor or other health professional ever told them that they had a specified condition. Asthma estimates are for current asthma and are based on the additional question "Do you still have asthma?" Arthritis includes arthritis, rheumatoid arthritis, gout, lupus, and fibromyalgia. Cancer excludes nonmelanoma skin cancer or skin cancer of unknown type. Diabetes includes all types with the exception of diabetic conditions related to pregnancy. Heart disease includes coronary heart disease, angina or angina pectoris, or heart attack or myocardial infarction. Hypertension is based on respondents indicating that on two or more separate visits they were told by a doctor or health professional that they had hypertension. Young adults who reported more than one condition are counted in each category.

§ 95% confidence interval.

¶ Estimate is statistically unreliable; data have a relative standard error of 20%–30%.

FIGURE 22-2 Percentage of young adults aged 18 to 29 years with selected chronic conditions, by sex. (From National Health Interview Survey, United States, 2005–07. http://www.cdc.gov/mmwr/preview/mmwrhtml/mm5825a3.htm.)

After age 25 years, the preventive emphasis is on modifying coronary disease risk factors. There is evidence that healthy lifestyle changes during young adulthood are associated with decreased

cardiovascular risk (Spring et al., 2014). The recommendations for screening for young adults are undergoing revision as more information becomes available about the interactive risks of sedentary lifestyle, high cholesterol levels, familial high lipid levels, diabetes mellitus, and smoking. For men aged 20 to 35 years the USPSTF makes no recommendations for or against routine screening for lipid disorders unless they are at increased risk of coronary disease (USPSTF, 2015). Aging is responsible for some degenerative changes in respiratory and cardiac function, but during the young adult years this decline amounts to less than 1% per year and is largely determined by an individual's fitness level (McCance & Huether, 2015). Cardiovascular assessment of the young adult includes determination of the presence of hyperlipidemia, hypertension, diabetes, chest pain, or heart disease. A *Healthy People 2020* target is to reduce the mean total blood cholesterol level among adults to 177.9 mg/dL; the baseline between 1988 and 1994 for adults aged 20 years or older was 197.7 mg/dL (USDHHS, 2015). This 2020 target set a goal of 10% reduction. From 2009 to 2012, 12.9% of persons aged 20 years or older had high total blood cholesterol levels (greater than 240 mg/dL); this is appreciably down from 21% for the 1988 to 1994 period. Nurses can assist in gathering a comprehensive health history including pertinent information about hypertension and **coronary artery disease** in parents and relatives. In women a history of pregnancy-induced hypertension or preeclampsia is important and a risk factor for cardiovascular disease and renal disease (Box 22-3: Research for Evidence-Based Practice).

Box 22-3

Research for Evidence-Based Practice

Effectiveness-Based Guidelines for the Prevention of Cardiovascular Disease in Women—Update

During the last decade there have been a number of randomized

controlled trials, such as the Women's Health Initiative, that have attempted to differentiate how cardiovascular disease (CVD) preventive strategies should be altered for women. The myth that CVD is a “man's” disease has been abolished. CVD caused more deaths in women than cancer, chronic lower respiratory disease, Alzheimer disease, and accidents combined. CVD deaths are much higher in black females than in white females. These guidelines thoroughly dispelled the conventional wisdom that as far as CVD is concerned, women should be treated the same as men. This is also a global problem. Heart disease is the leading cause of death in women worldwide. These guidelines also focus on preventive efforts and a long-term risk analysis in younger women.

The “ideal cardiovascular health” long-term pattern described by the American Heart Association includes levels of total cholesterol less than 200 mg/dL, blood pressure less than 120/80 mmHg, fasting blood glucose level less than 100 mg/dL, lean BMI less than 25 kg/m2, smoking abstinence, regular physical activity, and a diet based on the Dietary Approaches to Stop Hypertension (DASH) concept.

An important newer recommendation of these guidelines is that pregnancy history provides the health care professional with a criterion to predict future CVD risk. Women with a history of pregnancy-induced hypertension or preeclampsia have a significantly higher risk of CVD. The panel reviewed a large meta-analysis that indicated that women with a history of preeclampsia have approximately twice the risk of developing heart disease, stroke, and thrombolytic events in the decades after pregnancy. Pregnancy may induce a temporary state that is similar to early metabolic syndrome, and as such could be considered a failed stress test for the development of CVD in the future. Therefore it is highly recommended that the delivering health care personnel refer preeclamptic women after delivery to the primary care physician or cardiologist so that risk factors for CVD can be observed and adjusted to be more in accord with the “ideal cardiovascular health” pattern. Health care providers who are seeing females during a first visit should carefully review previous pregnancy complications, including

preeclampsia and gestational diabetes, preterm birth, and birth of an infant small for its gestational age. In addition, other health disorders, such as depression and autoimmune diseases (systemic lupus and rheumatoid arthritis), may also elevate the risk of CVD.

These recommendations also include cultural differences. An interesting finding points out the "ethnic paradox" where the female Hispanic population, despite the stresses of immigration and less access to medical care, has a longer life expectancy than non-Hispanic whites and non-Hispanic blacks.

Guidelines from Mosca, L., Benjamin, E. J., Berra, K., Bezanson, J. L., Dolor, R. J., Lloyd-Jones, D. M., et al. (2011). Effectiveness-based guidelines for the prevention of cardiovascular disease in women—2011 update. *Circulation, 123*(11), 1243–1262. These guidelines have also been published in other journals and at National Institutes of Health Public Access; the guidelines represent the work of many participating organizations and sponsors, including the Nurse Practitioners in Women's Health. Also from Melnyk, B., & Fineout-Overholt, E. (2011). *Evidence-based practice in nursing & healthcare.* Philadelphia: Lippincott Williams & Wilkins.

Hypertension results from increases in cardiac output or increases in peripheral resistance, or a combination of both, and is the third leading cause of death worldwide. According to a report from the Eighth Joint National Committee (James et al., 2014), the focus of blood pressure assessment is on systolic hypertension and risks from prolonged diastolic hypertension. The risk from diastolic hypertension starts to rise at 75 mmHg. The focus of attention is on lowering blood pressure toward the new lower normal goal of 120/80 mmHg or less (James et al., 2014; USDHHS, 2015). The USPSTF highly recommends (grade A) screening of young adults for hypertension. Increases in blood pressure above 140/90 mmHg in young adults contribute to a consistent rise in the risk of heart attack, stroke, and heart failure. The report from the Eighth Joint National Committee (James et al., 2014) and earlier reports discuss the significance of a new category of "pre-hypertension" to better identify individuals at risk of developing treatable hypertension and to encourage lifestyle changes before vascular disease is fully evident.

There are also noticeable disparities in the development of hypertension in various population subgroups. Data from 2009 to

2012 indicate the Mexican American and the white-only/non-Hispanic populations have the lowest percentage of high blood pressure individuals (27%), and the non-Hispanic/black American population has the highest (42%) level of hypertension (USDHHS, 2015). The prevalence of control of hypertension was also lowest in young adults (39%). This may be related to lack of a usual source of care, but most young adults surveyed had health insurance, so health insurance alone is not sufficient to correlate with better hypertension control (Gillespie et al., 2011). Gillespie and colleagues (2011) also report that adoption of healthy behaviors in young adults, particularly reducing dietary salt intake from an average of 3400 mg daily to an average of 2300 mg daily, could dramatically reduce the incidence of hypertension.

Although for the entire population deaths attributable to coronary heart disease have declined since the 1960s (CDC, 2011b), the mortality rate remains higher for American Indians/Alaska Natives and blacks. A prevention target of *Healthy People 2020* (USDHHS, 2015) is to increase the proportion of young adults aged 18 years and older with hypertension whose blood pressure is under control from 18% in 1988 to 1994 to 61.2%.

Metabolic syndrome includes a group of cardiovascular risk factors associated with overweight and obesity, particularly abdominal obesity. This syndrome includes the lethal risks of high lipid levels, insulin resistance, and hypertension. Many studies have demonstrated that hyperlipidemia and hypertension in young adults is directly related to later cardiovascular disease (Tran & Zimmerman, 2015). A prominent sign of metabolic syndrome is central or waist-centered obesity. Currently, at least one-fifth of US adults are estimated to have this combination of metabolic risk factors, and the prevalence increases with age. First-step therapy involves lifestyle alterations, including weight management and increase in physical activity.

Diabetes is seventh on the list of leading causes of death in the United States, and it is one of the six major chronic diseases affecting young adults. Currently, 23.6 million Americans have the disease, and

it is estimated to be undiagnosed in approximately 25% of Americans with diabetes. Minority populations (black Americans, Native American/Alaska Natives, and Hispanics) are disproportionately affected, with Native American populations experiencing twice the rate for new cases recorded in white non-Hispanic populations (USDHHS, 2015). The incidence of diabetes, especially type 2 diabetes (adult onset), and related complications (cardiovascular disease, blindness, lower limb amputations, and kidney disease) is increasing in the United States (USDHHS, 2015). Of those with diagnosed diabetes, only a few have their blood pressure, glucose levels, and cholesterol levels sufficiently controlled to avoid or delay vascular disease. Diabetes lowers life expectancy by up to 15 years. Because careful control can delay the beginning and progression of long-term complications, nursing efforts directed at early detection and monitoring of diabetes in young adults are important.

Decision-Making and Risk-Taking

The decision-making of a young adult directly affects health and well-being. Peak physical skills stimulate young adults to be venturesome, daring, enterprising, and aggressive. Young adults have less experience with the death of significant people in their lives, and they may take inordinate risks. The leading causes of death in individuals 15 to 24 years of age combined are unintentional injuries, homicide, and suicide (USDHHS, 2015). The prevalence of adverse behaviors associated with sudden death illustrates a developmental lack of fear in young adults. Bullying, dating violence, and sexual violence are becoming more prevalent. Underuse of seat belts and helmets by motorcyclists and bicyclists is a cause of many accidental injuries and deaths. Some states still do not have laws that require the use of helmets.

Communicable Diseases and Adult Immunization

Communicable (infectious) diseases affect young adults with differing degrees of severity. Although the increased availability of better drug

treatments and/or vaccines, improved hygiene and food handling, and provision of cleaner water supplies have promoted prevention and control of infectious disease, new disease threats are continually emerging. Much of this increase is due to improvements in travel and changes in social, sexual, and other behaviors that expose broader populations of individuals to emerging pathogens.

Current common threats include seasonal influenza, drug-resistant tuberculosis, diarrhea caused by *Escherichia coli* 0157:H7, hepatitis, and meningococcal disease. A more recent goal of *Healthy People 2020* is to increase the percentage of young adults who are vaccinated for seasonal influenza from 14.7% to 19.3% (depends on age group) to 80% (USDHHS, 2015). Even with nurse-staffed flu drives, this goal is difficult to reach in the young adult age group.

Increasingly, new cases of tuberculosis are occurring in foreign-born individuals (USDHHS, 2015), even as the incidence of this disease has declined overall to 3.6 cases per 100,000; the target is 1.0 new case per 100,000 population. An increase in tuberculosis rates, particularly in some minority groups (Asian American/Pacific Islanders, blacks, and Hispanics), illustrates that preventive activities must be reinforced and constant vigilance maintained over monitoring and effectiveness for all communicable diseases. The focus of tuberculosis surveillance is moving toward the tracking of full completion of drug protocols and treatment of drug-resistant types. New infectious agents and diseases continue to be detected and must be understood in a global context because of increasing travel and migration, importation of foods, agriculture practices, and bioterrorism (USDHHS, 2015).

Cases of acute **hepatitis B** have declined in young adults because of vaccination programs aimed at children, adolescents, and adults in high-risk groups (USDHHS, 2015). A primary way of achieving high levels of vaccination coverage is to identify settings in which unvaccinated young adults can be vaccinated, such as correctional facilities, drug treatment centers, and clinics treating sexually transmitted infections (STIs) (USDHHS, 2015). An objective of *Healthy People 2020* is to continue to reduce hepatitis B infections in adults aged 19 years or older from 2.0 cases per 100,000 persons in 2007 to a

target goal of 1.5 cases per 100,000 persons (USDHHS, 2015).

Another target of *Healthy People 2020* is to keep the incidence of hepatitis C stable at 0.2 new symptomatic cases per 100,000 persons (USDHHS, 2015). Chronic hepatitis became a nationally reportable disease in 2003. The individuals most at risk are those who have injected illicit drugs, are undergoing hemodialysis, are seropositive for **human immunodeficiency virus** (HIV), or have elevated liver enzyme levels. Recent curative advances in drug treatment for hepatitis C have made better case finding more important (USDHHS, 2015).

Most outbreaks of meningococcal disease are sporadic; however, young adults living in college/university dormitories or crowded conditions may be more susceptible than young adults not living in close settings. Although meningococci are sensitive to penicillin and many antibiotics, the case-fatality rate is high in otherwise healthy adults, and many survivors may have residual neurological disabilities. Those most susceptible are unvaccinated or incompletely vaccinated college first-year students living in dormitories, or military recruits, who have a higher case ratio (CDC, 2013c). Approximately 44% of people aged 13 to 15 years were vaccinated against meningococcal infection, and the *Healthy People 2020* goal is for more comprehensive coverage of 80% (USDHHS, 2015). Specific recommendations are also indicated to control sudden outbreaks of meningococcal disease.

Other viruses, such as **human papilloma virus** (HPV), commonly affect young adults. HPV is spread through sexual contact, and some forms of the virus in combination with smoking are strongly related to the later development of cervical dysplasia and cancer. The prevalence of HPV infection is highest among 20- to 24-year olds and peaked in the pre-HPV vaccine era (CDC, 2013b). A vaccine to prevent cervical cancer, Gardasil HPV vaccine, is effective against four types of the virus (HPV types 6, 11, 16, and 18); it is available and is recommended for individuals from 9 to 26 years old. *Healthy People 2020* recommends three doses of HPV vaccine for females 13 to 15 years of age. Twenty-eight percent were vaccinated in 2012, and the

target is 80% (USDHHS, 2015). Recent study findings report that the rate of HPV infection in younger women has declined as a result of increased HPV testing and vaccine use (Dickson et al., 2015).

Pertussis (whooping cough) vaccination is part of the original vaccine series offered to infants. As it is now known that the antibody titer protection for pertussis diminishes with age, pertussis vaccination is recommended with the 10-year tetanus booster injection. This newly formulated vaccine recommended for adults is known as Tdap (tetanus, diphtheria, acellular pertussis). Adults younger than 65 years who have never received Tdap should substitute it for their next 10-year interval booster dose (http://www.cdc.gov/vaccines/vpd-vac/combo-vaccines/Dtap-Td-DT/tdap.html).

Nutritional-Metabolic Pattern

Young adults value slimness, defined muscle tone, and athletic ability. Emphasis on body "thinness" can lead to improper eating. Regular physical activity increases muscle and bone strength, decreases body fat, aids in weight control, enhances well-being, and reduces depression. Physical activity levels are positively influenced by structural environmental improvements, such as sidewalks, bike lanes, and parks, and by legislative policies that improve access to physical activity facilities (USDHHS, 2015). An optimally functioning **basal metabolic rate** in the young adult allows adequate oxygen intake during normal activity and rest periods. A young adult male requires approximately 1600 to 1800 calories a day to meet his body's basal metabolic needs, and a young adult female requires only 1200 to 1450 calories a day. After growth in height stops in the late teens, the basal metabolic rate declines.

During the young adult years, caloric intake increases substantially, particularly in men. Increased caloric intake without a corresponding increase in energy expenditure can lead to obesity, which is a precursor to hypertension, coronary disease, and diabetes. The presence of obesity meets three defining criteria for disease: impairment of function, attributable signs and symptoms, and

contribution to bodily harm (Ryan & Urquhart, 2015). According to information from 2009 to 2012, 35.3% of adults aged 20 years or older were at a healthy weight (USDHHS, 2015).

Although trends toward increasing weight occurred in all major racial and ethnic groups, the increase in obesity was more pronounced in the 2009 to 2012 survey period for the Hispanic population (40.5%) and the Mexican American population (42.8%) (USDHHS, 2015). In the same survey period, the prevalence of obesity among men aged 20 years or older was 34.3%, and in women aged 20-years or older it was 36.1% (USDHHS, 2015). To stabilize the trends in increasing weight and obesity, the nurse can be part of education directed toward new lifestyle, nutrition, and physical activity behavior.

For many Americans, food sources are abundant, portion sizes have increased, and lifestyles are becoming increasingly sedentary. More specifically, young adult diets should contain a variety of nutrient-dense foods, especially whole grains, fruits, vegetables, low-fat or fat-free milk, lean meats, and protein sources. Caloric intake and the intake of saturated and trans fats, cholesterol, added sugars, sodium, and alcohol should be limited. Food-label information (now includes trans fats) should be read on all processed and packaged foods. Another challenge is the increasing consumption of food prepared and eaten away from home, which is generally higher in fats, cholesterol, and sodium and lower in fiber and calcium than that prepared in the home (USDHHS, 2015). This suggests that the composition of food prepared outside the home promotes weight gain. Many states have legislation that requires restaurants and fast food outlets to list food composition on menus. There is some evidence that in poor areas with less access to transportation, neighborhood convenience stores stock nutrient-poor snacks, sugar-sweetened drinks, and less fresh fruits and vegetables and that has contributed to lower diet quality (Rummo et al., 2015). Collective national action and community involvement are needed to promote healthful diets among all Americans and to reverse the increasing trend to be overweight and obese. Whereas diet drugs and bariatric surgery may be advised for cases of severe obesity, these treatments

must be evaluated for risks and benefits (Burke & Wang, 2011). Young adults, in particular, are influenced by the body shapes of celebrities, and "celebrity worship" may be an important motivator to seeking change in body shape and plastic surgery alternatives (Maltby & Day, 2011).

Nurses with other health providers can investigate weight problems by measuring waist circumference, blood pressure, cholesterol levels, and activity levels rather than using weight alone. Assessments of weight and height are used to calculate BMI. Whereas the BMI may be a good indicator for population screening, it may not be the best measurement for predicting health risks as in each individual person cardiovascular and obesity-related complications must be assessed (Ryan & Urquhart, 2015). Those with a BMI of 25 kg/m2 or less (male waist size of 40 inches or less, female waist size of 35 inches or less) should have weight maintenance teaching. Individuals with a BMI of 30 kg/m2 or greater who have tried diets and exercise may be considered for weight-reducing drugs (CDC, 2010; LeBlanc et al., 2011). A BMI of 35 to 40 kg/m_2 or above may meet the criteria for bariatric surgery (CDC, 2010; LeBlanc et al., 2011). However, the focus of nursing advice is conservative at first, recommending lifestyle management, careful diet appraisal, and increase in exercise patterns (Ryan & Urquhart, 2015). Use of activity monitors such as FitBit, heart-rate monitors (Apple watch), and fat/muscle calculators may provide incentives for health eating and exercise patterns. Long-term weight management is a frustrating process. Applying principles of motivational interviewing (collaboration, evocation, autonomy) and addressing the problems of obesity and overweight through use of a chronic care model offers potential for long-range weight management (Apovian & Gordon, 2014; Ryan & Urquhart, 2015). Changing the upward obesity population trend is one of the most difficult goals to achieve (Jiang et al., 2011). The nurse should use people-first and nonjudgmental language that refers to the person before the disability (diabetes) rather than identifying the person on the basis of the disability (diabetic) (Ryan & Urquhart, 2015).

Proper nutrition is particularly necessary for the young adult female

during the childbearing years. The factors contributing to iron deficiency in this age group are regular loss of blood (during menses) and pregnancy. The prevalence of anemia in women of childbearing potential was 16.1% in 2003 to 2006, and the 2020 target is 14.5% (USDHHS, 2015) (see the case study and care plan at the end of this chapter). A blood loss of 2 to 4 mL per day (1–2 mg of iron) can cause iron-deficiency anemia; young women who do not eat a healthy diet and have heavy periods or use nonsteroidal antiinflammatory drugs are specifically at risk of iron-deficiency anemia. Iron supplementation is recommended during pregnancy for optimal growth of the fetus and supporting structures (Perry et al., 2013). The CDC and the USDHHS (2015) recommend that all women of childbearing age consume 0.4 mg of folic acid daily to reduce the risk of **fetal neural tube defects,** including spina bifida. The supplementation period should include at least the month before pregnancy and the first trimester during pregnancy. The CDC and the US Food and Drug Administration (FDA) also recommend folic acid fortification of food to prevent neural tube defects (USDHHS, 2015). In 2007 to 2010, only 22.8% of nonpregnant females aged 15 to 44 years reported a daily intake of folic acid of 400 mcg from fortified foods or dietary supplements; the target for 2020 is 26.2% (USDHHS, 2015). Efforts are also being made to reduce health disparities in neural tube defects, including the use of better communication modalities with the Hispanic population and other population subgroups that have higher rates of neural tube defects (USDHHS, 2015).

Most adolescents and adult women fail to meet their calcium requirements, placing them at risk of osteoporosis and bone fractures in later life. Low calcium intake is a direct result of low milk consumption related to soft drink ingestion. An increase in intake of calcium-containing foods is therefore recommended, particularly for teens and young women (see Chapter 11).

Elimination Pattern

Patterns of elimination are generally well established by young adulthood. Although eating disorders (anorexia and bulimia)

typically begin at an earlier stage of development, they can persist during young adulthood. The fashion industry is widely criticized for using underweight women as young female models, thereby emphasizing excessive thinness as the ideal female standard.

Assessment of young adults is also directed toward teaching about the common complaints of constipation, hemorrhoids, and occasional diarrhea. Although the risk of colon cancer is low in this age group, young adults should be aware that changes in elimination patterns or blood in the stool should be reported to their primary care provider. Nurses can counsel young adults on the benefits of drinking adequate amounts of fluid and eating fruits and vegetables, which are sources of fiber, to promote normal bowel activity.

Activity-Exercise Pattern

Inactivity is a factor predisposing to cardiovascular disease and obesity; increasing access to and promoting locations for physical activity are increasingly emphasized. A *Healthy People 2020* goal is to reduce the proportion of adults who engage in no leisure-time physical activity. In 2013, 30.5% of adults engaged in no leisure-time physical activity; the target was 32.6%, which was reached, but there is much room for improvement (USDHHS, 2015).

Aerobic exercise, in which oxygen is metabolized to produce energy, develops an optimally functioning cardiorespiratory system. Aerobic conditioning achieves cardiovascular fitness through five periods of moderately intense exercise weekly for approximately 30 minutes or more (USDHHS, 2015) at a heart rate of approximately 220 minus the age of the person multiplied by 65% to 85%. Although this formula is controversial and there may be individual variations, it seems a reasonable first approach. Young adults are encouraged to engage in fitness activities that increase the heart rate to approximately 150 beats or more per minute. After 5 minutes of activity at this rate, the body is required to make adjustments in cardiovascular capacity by enlarging the lungs and the capillaries in the muscles and the heart. Repeated aerobic exercise, such as swimming, cycling, running, and walking, decreases the likelihood of

problems caused by inactivity. Muscle-strengthening activities should also be stressed. Major barriers for young adults are lack of time, lack of access to exercise facilities, and inability to find safe environments in which to exercise.

Radiation and Excessive Sun Exposure

Nurses need to educate young adults about the risks of sun exposure and tanning, the preventive use of sun-blocking agents, and the awareness of skin symptoms that might indicate cancer. Sun-blocking agents reduce sunburn or other skin damage with the goal of lowering the risk of skin cancer. A number of the agents are rated on the basis of skin type and sensitivity to burning. Many lotions and creams are available with differing radiation protection levels. **Sun protection factor (SPF)** index is a measure of the effectiveness of various preparations. The agents are rated on a scale by the FDA. For example, a rating of 30 means the sunscreen provides 30 times the protection of unprotected skin. Newer guidelines for sunscreen protection were adopted in June 2012 by the FDA. New sunscreens should provide broad-spectrum protection, SPF of 30 or greater, and water resistance (American Academy of Dermatology, 2011). Women's makeup preparations and moisturizers may include sun-blocking agents. Young adults should avoid sunbathing during the 2-hour period before and after noon, because two-thirds of the day's ultraviolet light comes through Earth's atmosphere during this time. Sunscreens that block both ultraviolet A and ultraviolet B light are more effective in preventing cancer than those that block only ultraviolet B light (American Academy of Dermatology, 2011). The best protection is achieved by application of agents 15 to 30 minutes before exposure and then reapplying every 15 to 30 minutes during exposure to the sun. Further application may be necessary if activities involve swimming, sweating, or rubbing of skin. Sun-protective measures such as use of sunscreen, use of sun-protective clothing, and avoidance of ultraviolet light are an essential part of young adult education. The nurse considers that the most effective skin cancer prevention activities for young adults include primary care

counseling, sun protection, and avoidance of the use of tanning beds (DiStefano et al., 2014).

Sports

Bicycling and motorcycling are encouraged by environmentalists to decrease automobile pollution; this trend is also promoted to relieve traffic congestion, avoid the high costs of fuel and car maintenance, and increase interest in healthy exercise. Cyclists are at risk of being involved in accidents with automobiles. Head injury is responsible for many bicycle-related fatalities. In 2013, 19 states had mandatory helmet requirements for riders younger than 15 years (USDHHS, 2015). Bicycle helmets are believed to be the single most effective preventive measure available to decrease the incidence of brain and head injury (USDHHS, 2015).

Motorcycles have less occupant protection than do automobiles but are appealing to young adults, primarily because they have high-performance and speed capabilities. Use of a motorcycle helmet reduces the chance of dying in an accident. A target of *Healthy People 2020* is to increase the proportion of motorcyclists using helmets from 60% in 2013 to 74% in 2020 (USDHHS, 2015).

Accidental deaths from drowning are also common in young adults. The USDHHS (2015) estimates 1.2 drownings per 100,000 population occurred in 2013. Swimming, boating, and scuba diving are associated with the high number of water-related fatalities. Hang gliding, parachuting, and flying small aircraft are responsible for a large number of outdoor fatalities. Mountain climbing, hiking in poor weather conditions, downhill ski racing, and bobsledding are other hazardous activities. Many so-called accidents are not random, uncontrollable events, but are predictable and preventable if precautions and risks are analyzed (USDHHS, 2015).

Amateur and professional sports activities generally pose few hazards when rules and safety precautions are observed. Relatively few fatalities are associated with the professionally organized contact sports, such as football, hockey, or boxing, but chronic injuries and concussions can cause degenerative brain diseases. In 2013, 45.6

medically consulted injuries occurred per 1000 population, and the target for 2020 is 41.9 per 1000 population (USDHHS, 2015). In addition, pathological investigations by Daniloff (2010) and other Boston University researchers have linked sports-related head injuries to an increase in the incidence of dementia, memory-related diseases, and chronic traumatic encephalopathy (Mez et al., 2016). This has resulted in significant changes in professional football policies and sports concussion protocols. Many of these policy changes have been adopted for college, high school, and amateur sports programs as well (Daniloff, 2010).

A comprehensive history of recreational activities alerts the nurse to specific needs about safety education. Young adults are encouraged to learn and abide by the rules of the sport in which they are engaged. Rules in many sports have evolved from health and safety concerns, enabling the individual to learn the sport well with appropriate instruction.

Sleep-Rest Pattern

Young adults are subject to fatigue induced by work, **stress**, or inactivity. Changes in activity or stressors can help reduce fatigue. Attempting new and challenging tasks can help reduce mental stress. New physical activities, such as learning a new sport or form of exercise, can also provide stimulation. A number of digital devices now record sleep as well as activity patterns.

Cognitive-Perceptual Pattern

Physical and Mental Patterns

Visual acuity is highest at approximately age 20 years and begins to decline at approximately age 40 years, when farsightedness frequently develops. Hearing is also best at age 20 years; the ability to distinguish high-pitched tones decreases with age. The other senses—taste, smell, touch, and awareness of temperature and pain—remain stable until age 45 to 50 years.

Further maturation requires young adults to learn skills and

behaviors that increase the performance abilities gained as adolescents. The factors that an individual young adult may perceive as essential to learn will depend on specific goals, values, attitudes, and practices as influenced by intrinsic (constitutional) and extrinsic (environmental or community) factors. Executive decision-making becomes better developed: calculation of risks versus rewards, prioritizing, self-evaluation, self-correction, and long-term planning become more sophisticated. The development of intellectual maturity influences the selection of behaviors and attitudes that affect health and well-being practices.

Piaget's Theory

Several stage theorists have described the growth of young adult thought and moral development. It is important to note that these stages are fluid, and individual differences occur. Within Piaget's cognitive-developmental theory, formal operational thought evolves from concrete operational thought in adolescence and extends through the reasoning process of young adults (Piaget, 1972). Although more recent developmental theorists dispute Piaget's findings, this scheme of cognitive development assists the nurse in learning about and understanding young adult reasoning (Carey et al., 2015). Achievement of formal operational thinking allows young adults to analyze all combinations of possibilities and construct hypotheses. Young adult thought becomes more perceptive and insightful; issues can therefore be evaluated realistically and objectively. Young adults are energetic and can therefore contribute substantially to social and occupational decision-making. Although they tend to take greater risks, young adults typically demonstrate the use of appropriate reasoning, anticipation, and analytical approaches.

Intellectual Growth

Organization of information influences memory. Evidence shows that recall performance diminishes with age: at its peak in the 20s, memory starts to diminish during the 30s. Improved strategies for organization

of information, however, can enhance recall, and limitation of memory with increasing age is likely a result of retrieval rather than storage mechanisms. Recent evidence from brain development research indicates that during the early years of young adulthood important frontal lobe brain development is still occurring; this is important for control of emotions and later full adult rational decision-making (Neinstein, 2013).

Erikson's Theory

Erikson (1993), another widely cited psychological theorist, reported that the most important goal for young adults is the development of an increased sense of competency and self-esteem. In developing self-esteem, the young person learns to be truly open and capable of trust through the formation of intimate relationships that are characteristic of this period. This stage is described as a phase of psychosocial development termed **intimacy versus isolation** and loneliness.

Erikson's concept of genuine intimacy extends beyond sexual relations to a broader view of mutual psychosocial intimacy with a spouse or lover, parents, children, and friends. Characterized by the reciprocal expression of affection, intimacy requires mutual trust. These interchanges are spontaneous for the young adult; relationships should be free and allow self-disclosure. Young adults who are unsure of their identity may avoid intimate contact or engage in promiscuous behavior lacking in true intimacy, which can result in isolation and consequent self-absorption. Healthy adults search for continuity, regularity, or unity of meaningful relationships, while avoiding situations of little commitment.

Moral Development

Young adults who have successfully mastered the previous cognitive, social, and moral stages are usually able to recognize or use principled reasoning. Kohlberg identifies this ability as the **postconventional level of moral reasoning** (Kohlberg & Lickons, 1986). During this phase the individual is able to differentiate the self from the rules and

expectations of others and to define principles regarding rights in terms of self-chosen principles. The interests of individuals can be weighed against the needs of society and the state, and violations of law can be justified when individual interests are in accord with principles. Gilligan (1982, 2002, 2013), who studied the development of moral reasoning in women and girls, asserts that their moral judgments reflect less of a "rights" perspective and more of an emphasis on responsibilities in relationships. Newer framing of this theory of women's emotions and relationships is now essential to understanding intelligence and self-awareness (Gilligan, 2013).

Although development of principled moral reasoning is possible during young adulthood, it may never occur if the cognitive and social factors that stimulate higher reasoning are not present. Acts of personal violence representative of lower moral reasoning should not be present; however, such acts do occur during this period, illustrating the need for moral developmental concerns to be addressed at earlier stages of education and socialization.

Self-Perception–Self-Concept Pattern

In non-Western cultures the entrance to adulthood is generally defined and marked by social events such as marriage. In Western societies, maturation is defined through the individual's achievement of financial and residential independence, and is a more drawn-out, gradual process. There is evidence that young adults have recently been attaining traditional life milestones later; this includes completing school and leaving home, attaining financial independence, marrying, and having the first child (Neinstein, 2013).

Two emotional themes regarding the value of work and financial independence become evident during young adulthood. During their 20s, young adults yearn to explore and experiment, keeping structures temporary and reversible. These individuals may move from job to job and relationship to relationship, remaining in a transient state. At the opposite extreme is the urge to prepare for the future by making firm commitments. During this period, both men and women question their value to society, the merit of their accomplishments,

their success as sexual beings, and the probability of attaining their unfulfilled goals.

The US Census Bureau (2011) reports that more than 74.7% of women aged 25 to 35 years were employed in 2010; this percentage is expected to be approximately the same (74.2%) in 2018. As more mothers enter the labor force, the need for child care increases. The wage gap, or pay differential, between men and women is also significant. Recent legislation signed by President Barack Obama ensures women equal pay in the workforce (Morelli, 2015). Access to insurance and retirement benefits may not be available, especially to high-risk groups such as minorities or people receiving the minimum wage. Even when there is sufficient access to health care, some types of employment expose individuals to occupational risks and hazards.

Many young adults are high achievers and seek opportunities to be challenged. Employment problems are stressful and traumatic to an individual's self-esteem and self-worth, particularly in the current economic environment. The failure to obtain promotions or pay rises can accelerate the degree of stress. Employment is more than a source of income; it provides self-esteem and social interaction. Because the adjustment to the job market influences many other aspects of daily living, young adults frequently require assistance in developing coping mechanisms to manage stress. Properly managing the initial stress prevents further complications that can arise if the young adult uses unhealthy stress relievers such as alcohol or drugs.

Young women have many of the same concerns about employment and success as do young men. Many young women postpone childbearing until they have established their careers; many are absent from the job for only a standard maternity leave. Women who return to work when their children are very young frequently risk the emotional strain caused by guilt feelings and role strain. In addition to helping parents cope with the stress of being absent from their children, nurses can help them identify ways to provide high-quality supervision in their absence, through private babysitters, through day care programs, or through neighbors, friends, and relatives.

The US workforce is changing dramatically as companies merge,

restructure, downsize (right size), and shift employees around to meet changing market conditions, company mergers, and buyouts. The nature of work is changing, with a continued trend toward longer hours, increased use of contracted and temporary workers, and increased telecommuting (USDHHS, 2015). There is increasing concern about "globalization," outsourcing, and moving jobs overseas, especially in the industrial centers, the pharmaceutical industry, and the computer industry. Unemployment or underemployment for young adults is a particular concern after recovery from the prolonged recession beginning in 2008 (Rampell, 2011). There is concern that even with better job prospects, this young adult population will be behind in wages for years, and this may impact overall lifetime earnings. Younger hires may start at lower salaries and begin their employed years with firms that pay less or have less potential for advancement. If they have employment within their specific fields, it may come with fewer benefits than for more experienced, older workers (Neinstein, 2013). Nursing activity in occupational and industrial settings can be directed toward improving both working conditions and employer-employee relationships. When nurses advocate healthy work sites, this increases the chance that young adults will have access to comprehensive health-promotion programs.

Roles-Relationships Pattern

Young adult friendships are more enduring than are earlier relationships. The focus of the relationship is the sharing of feelings or confidences as well as common interests. True friendship is characteristic of a person who wants to give rather than receive. Friendships are necessary in a constantly changing society; they provide a source of emotional support and a basis of stability for developing the self-concept. Social networking sites such as Facebook, MySpace, and Twitter and social apps allow young adults to interact quickly with one another to organize events/dates and share photos, experiences, thoughts, and perceptions. Young adults use Internet dating services to widen access to potential dating candidates (Murray

& Campbell, 2015).

Establishing interpersonal relationships involves agreeable and purposeful interactions with others. Interpersonal relationships can be created with people of the same or the opposite sex. Age is typically a less important factor than it was during adolescence. The formation of intimate relationships develops within or outside a family context, the school setting, or work environment. High-speed cell phone and wireless Internet access facilitate maintenance of relationships from high school and university settings with text messaging, e-mail, and instant messaging.

For some the significant other is a person of the same sex. Among those aged 18 to 44 years, 92.3% of women and 95.1% of men reported they were heterosexual, and 1.3% of women and 1.9% of men stated they were homosexual, gay, or lesbian (Copen et al., 2016). Coming to the realization that a significant other is of the same sex often causes emotional upheaval and distress. Same-sex marriage (also known as gay marriage) legislation has been upheld by the US Supreme Court and applies to all US states; this legislation legitimizes the legal rights of same-sex couples through marriage or civil union statutes. Same-sex marriage supporters argue that civil recognition reduces the legal discrimination involved in such unions. Resistance to legalization of same-sex marriage comes from individuals who note that historically the term "marriage" has been reserved for a religious union between a man and a woman. This issue has been fiercely debated politically in the United States.

Transgender issues and rights have been headlines in the news recently. Transgender issues arise when one's gender identity or expression does not match the individual's assigned sex. Transgender expression is independent of sexual orientation as individuals may be heterosexual, homosexual, or bisexual. This category includes individuals who have reassigned their sexual identity different from that assigned at birth.

In addition to achieving intimacy, the young adult must accomplish other developmental tasks to achieve true psychosocial maturation (Figure 22-3). Decision-making about life and career directions is the

developmental milestone that heralds the transition from adolescence to adulthood. Decisions usually entail establishing independence from the family of origin. This transition may involve an actual physical move from the parents' home (going away to college, abroad, joining the military, or getting an apartment); however, movement away is not the sole indicator of independence (Figure 22-4). Young adults frequently remain in their parents' home for economic reasons, particularly when life choices involve continued schooling, unemployment, or remaining unmarried. In some cultures, unmarried adults live with their parents until they are married, and newly married young adults share the home of their parents until they begin having their own children.

FIGURE 22-3 Young adults enjoy gathering in a local café to socialize together.

FIGURE 22-4 Young adults may travel before marriage or beginning a career.

A greater proportion of young adults are enrolled in higher education than ever before (Pew Research Center, 2012). Many low-income young adults are enrolled at for-profit institutions, which have become the fastest growing sector of US higher education (Institute for Higher Education Policy, 2011). Because college loan repayment typically begins 6 months after graduation, new graduates have to face the harsh realities of trying to find employment and ways to begin loan repayment. Some reports indicate that up to 85% of new college graduates are moving home at least for a short time (Byrne, 2011). Others will start or attend graduate school to obtain better work skills.

Individuals in the later years of this age group typically choose life partners and begin families; they make decisions about childbearing and the number and education of children. Additional consideration must be given to decisions related to childbearing, such as finances, safety, family support, where to live, the relationship with extended family members, and the roles and responsibilities within the nuclear family unit. Young adults who are establishing a family must have

open communication about self-development, which includes issues of dual careers, childrearing practices, and domestic duties.

Family harmony and development are major goals for many young adults. Although family size and structure have undergone dramatic changes in recent decades, concern about each member's health and safety continues to be a primary focus. Family life is influenced by the qualities of individual family members. Typically, economic security, status, place in the community, and healthy patterns of living, such as good nutrition, personal hygiene, and physical fitness, are associated with healthy family adjustment.

Separation and Divorce

Approximately half of marriages end in divorce (US Census Bureau, 2011), and many young adults do not marry but have children. Approximately one-quarter of all children in the United States are living in single-parent, mother-led families, and half of the children affected by divorce frequently never see their fathers again. Although dissatisfaction and unhappiness are frequent precursors to separation and divorce, the decision to dissolve a marriage is not easy. Considerable emotional strain exists for both partners, their children, their families, and their close friends. Divorce requires that young adults reevaluate their basic values, individual personality, spiritual beliefs, and ego strength, job potential, and socioeconomic factors to ensure future security for themselves and their children. Some young adults are unable to adjust to role and status changes and to threats of self-concept. For these reasons, support systems in the form of groups, individual counseling, or special social activities are critical. Nurses can assist young adults to identify sources of assistance (Box 22-4: Innovative Practice). As a result of the dissolution of families or divorce, many women and their young children are forced to seek emergency shelter in publicly operated homes, including welfare hotels and group shelters.

Box 22-4

Innovative Practice

Social Media and Use of Internet and Cell Phone Delivery Systems for Preventive Health Information

The use of technology is changing practice patterns and the way that health communications may be transmitted. The transference of technology has often been slowed by the reluctance of policymakers, administrators, providers, advocates, or consumers. Some biomedical innovations for Pap test understanding and prevention of sexually transmitted infections and HIV infection have been adopted (such as use of electronic health records and cell phones/Internet to trace contacts), but full adherence by the person seeking care is often hindered by behavioral factors. Technological interventions allow behavioral supports and educational programs to be delivered with less cost and more convenience. These include STI/HIV testing and partner interventions, behavioral interventions, self-management strategies, and provider care information. These technological interventions have been demonstrated to be as effective as face-to-face interventions. Text messaging is also possible. Smartphones are connecting many individuals domestically and globally. This will allow the dissemination of more active engaging health diagnosis, treatment, and counseling.

From Christensen, S. & Morelli, R. (2012). MyPapp: A mobile app to enhance understanding of Pap testing. *Computers, Informatics and Nursing, 30*(12), 627–631; Swendeman, D., & Rotheram-Borus, M. J. (2010). Innovation in sexually transmitted disease and HIV prevention: Internet and mobile phone delivery vehicles for global diffusion. *Current Opinion in Psychiatry, 23*(2), 139–144.

Nursing care and assessment can help to identify the feelings of guilt, grief, and loss that young adults experience during a separation or divorce. Suggesting that young adults read articles or books on issues related to divorce is helpful, because they provide a reference point for their experiences. The nurse recommends marital counseling by a qualified professional; this may be the most beneficial source of support.

Male and Female Risk of Violence

Violence is a global and national health problem. Violent deaths are intentional deaths that occur from physical force or power exerted against self, others, or a community (CDC, 2011a). Although the destruction of the World Trade Center in 2001 and violent events in other countries such as France, Belgium, Iraq, Afghanistan, and Syria and ISIS (radical Islamic governance) are examples of organized terrorism, worldwide only approximately one-fifth of violent acts are related to organized events. The overthrow of governments in Egypt and Libya was largely accomplished by young adults. Young adults can be involved as both the agitators and the victims of violence.

In the United States there are approximately 51,000 violent deaths a year, and these deaths affect all Americans not only in emotional terms but also through additional medical costs and lost employment productivity (CDC, 2011a). Domestically, in the United States, the recipients of violence may be older adults, children, and women with whom they are familiar (USDHHS, 2015). Identification of, education about, and strategies to prevent bullying, dating violence, and sexual violence among young adults requires federal and community attention. Homicide (assault) is the second leading cause of death in the 15- to 24-year-old age group and the leading cause of death for black men in the same age category (Neinstein, 2013; US Census Bureau, 2011). Between 1999 and 2008, the homicide rate remained fairly static at approximately 5.4 deaths per 100,000 population; this is a significant decline from the rate seen in the early 1990s, and there are ongoing efforts to understand what has contributed to the reduction (USDHHS, 2015). Firearms are involved in approximately two-thirds of these deaths, and men have twice the risk of dying as do women (US Census Bureau, 2011). When compared with the general population, death rates are higher for men in poorer populations, in urban areas, and with less formal education. Homicide is closely associated with alcohol and drug abuse and is frequently related to other violent acts, such as assaults and robbery. Other risk factors include a history of loss of employment, detention or prison experience, access to firearms, abuse in the home, mental illness, social

isolation, and homelessness. The presence of firearms in the home is associated with the increased risk of unintentional and intentional injury to children. A target in *Healthy People 2020* is to reduce firearm-related deaths from 10.5 per 100,000 population in 2012 to 9.3 per 100,000 population and to reduce the number of nonfatal firearm-related injuries from 20.9 per 100,000 in 2010 to 18.6 per 100,000. The firearm-related death rate for young black men and boys was nearly five times the rate for young white men and boys (USDHHS, 2015).

Intimate partner violence has serious health consequences for women and men; however, because of social and legal factors, it is probably the most underreported form of abuse (Box 22-5: Diversity Awareness). Abuse crosses all socioeconomic, racial, ethnic, religious, gender, and age boundaries. Approximately 3 in 10 women and 1 in 10 men during their lifetime report intimate partner violence or abuse. Women report higher lifetime and more recent-year intimate partner violence than men (Black et al., 2011). Nurses and other primary health care providers assist in detecting or treating violence or abuse in an optimal manner; they can help others to understand the cultural background of abuse. However, more efforts must be made to recognize the scope of the problem and to provide appropriate counseling (see Box 22-5: Diversity Awareness). Physical assaults by intimate partners decreased in the last decade; this reduction is attributed to increased economic opportunities for women, increased age at first marriage, and better access to domestic violence services. A target in *Healthy People 2020* is to reduce the rate of physical assault to 19.2 assaults per 1000 from 22 assaults per 1000 recorded in 2012 (USDHHS, 2015).

Box 22-5

Diversity Awareness

Partner and Family Violence: Gender and Culture Differences

Assessing the Problem

Epidemiological researchers have attempted to determine the risks for intimate partner and family violence. Intimate partner violence includes four behaviors: physical violence, sexual violence, threats of physical or sexual violence, and/or emotional abuse. Understanding the roots of partner violence has been more difficult than ascertaining determinants of physical disease. The victims of family violence are usually children, the female spouse, intimate partners, and elderly people (Black et al., 2011). Factors associated with intimate partner violence include young age, low income, pregnancy, mental health problems, separation or divorce, and a history of abuse. The unequal position of women in a relationship and the manner in which conflict is managed, as well as differences in culture, education, and prestige associated with the partners' occupations, are related to the risk of violence. Domestic violence is a problem in all age, ethnic, and religious groups; in some cultures, attitudes toward women even legitimize the practice. Women who have gained positions of respect and power outside the home through activities in their neighborhood or community are less likely to be abused. In men and women, viewing abuse as a child increases the likelihood that abusive behaviors are used by these same individuals as adults (Landenburger & Campbell, 2012).

Are Nurses Willing to Take Action?

Some studies indicate that nurses have been reluctant to take action regarding violence against women or men. Some of the traditional reasons for not taking action are based on paternalistic attitudes, in which the victim is blamed for his or her part in the social situation that becomes violent. Nursing's strong advocacy stance and emphasis on the communication of nonjudgmental, genuine concern should provide a strong foundation to avoid blaming the victim and to focus on pathological factors that have been identified by much of the health profession's research in this area.

How Can Nurses Recognize Abuse?

Research demonstrates that nurses should be more aware of indicators of partner violence. These include the presence, as revealed by a health history, of separation or divorce, alcoholism, frequent verbal disagreements, and high levels of conflict. Other warning signs include repeated visits to emergency departments, complaints of headaches or backaches, psychiatric illness, and incidents of bruises, sprains, and lacerations. Abusers are more likely to have hostile personality styles with aggressive tendencies. As children, they may have had unattainable goals, and their achievements may have been met with harsh criticism and toxic and depersonalizing behavior (Landenburger & Campbell, 2012). Abusers may also use passive aggressive tactics, turning passive withdrawal and blaming behaviors against the helping individual in an effort to portray the abuser as a victim.

What Do You Think?

- Are nurses less than helpful in their detection and management of domestic violence? Why do you think this occurs?
- Are nurses, because of their education and sensitization to people with mental problems, more or less likely than others to experience violence in their own domestic settings? Explain why.

Sexuality-Reproductive Pattern

By young adulthood the menstrual cycle is generally well established in the woman. Cyclical hormonal function is responsible for regularity of the cycle and normal functioning of the ovaries and uterus. The normal duration of menses is 4 to 5 days (range of 2–7 days, with a blood loss of 40 mL). Blood loss greater than 80 mL per cycle is

abnormal and may lead to anemia. Irregularities such as painful menstruation, premenstrual syndrome, and prolonged or heavy bleeding need further assessment. Although these problems are not always abnormal, the symptoms and the individual's reaction to them can signal functional disorders and the need for further investigation and treatment.

Reproductive Problems

Infertility is defined as the lack of conception in the presence of unprotected sexual intercourse for at least 12 months. Approximately 10% to 15% of couples of reproductive age in the United States are believed to be infertile (Perry et al., 2013). Infertility has become more of a public issue since the advance of assisted reproductive technologies, such as in vitro fertilization and gamete intrafallopian transfer, which can enable couples with known reproductive problems to conceive children. These technologies frequently create great stress for the couple and often result in marital conflicts and distress. Infertility is not an issue for those in the 18- to 25-year age range as peak fertility is from age 20 years to age 35 years; however, after the age of 30 years, infertility is more common and a more specific diagnostic workup or referral for some type of assisted reproductive strategy may be indicated.

Common problems of the male reproductive system include **orchitis**, epididymitis, and varicoceles and hydroceles. Mumps in the postpubertal male can cause swelling of the testes, orchitis, and subfertility. Even with appropriate vaccination, mumps cases are becoming more prevalent as the mumps vaccine is not fully effective (Lewis et al., 2015). External conditions such as fungal infections, contact dermatitis, and eczema; parasites such as mites (scabies) and lice; and nonvenereal diseases such as erysipelas, abscesses, and fistulas can occur in the scrotum.

Unintended Pregnancy

According to the US Census Bureau (2011), the teen birth rate in the

United States has been declining since 1990. Improved child health and development is associated with healthy planned pregnancies. Unwanted or unplanned pregnancies can be a considerable source of stress to young adults. Unintended pregnancy is an important public health issue and relates to increased risks of delayed prenatal care, depression, and other personal and relationship problems (USDHHS, 2015). Family planning is one of the biggest public health achievements of the 20th century. Despite the advent of modern contraceptives, unintended pregnancy remains a persistent problem. Approximately half of all pregnancies are intended (USDHHS, 2015); in 2006, 51% of all pregnancies among females aged 15 to 44 years were intended, and the target for intended pregnancies in the United States in 2020 is 56%. Although most young adults consider family planning services as an essential basic health service, health insurance plans historically have attempted to manage and limit such services (USDHHS, 2015). Under the Affordable Care Act, preventive health for women must be covered with no cost sharing. This would include all FDA-approved contraceptive and sterilization methods, in addition to appropriate teaching and counseling (ACA, 2017). The current lower pregnancy rates among teens seem to result from increased involvement in school activities, effective birth control and pregnancy prevention programs, and expanding job opportunities.

College women have high rates of reported sexual violence, STIs, and unintended pregnancy that result most often from the influence of alcohol on risky behavior, lack of negotiation for **sexual consent**, and haphazard contraceptive use (Fantasia et al., 2014). First-year students are particularly vulnerable (Demers et al., 2015). To address these problems, colleges and universities have adopted stricter institutional policies and educational programs aimed at making college students fully aware of what an authentic sexual consent entails to protect victims (DeMatteo et al., 2015). The recent reporting on the inadequacies of college/university policies on sexual consent has forced higher education institutions to be more proactive and forthcoming with early incoming student counseling and elaborate policies governing appropriate student campus behavior.

Approximately half of unintended pregnancies are the result of contraceptive failure. Both married and unmarried young adults need information about contraceptives (Table 22-2) to decrease the number of unwanted pregnancies and the need for abortions. The nurse's role in contraceptive counseling involves helping individuals to choose the method most appropriate to their needs. New and improved contraceptive agents are continually becoming available (Nelson, 2015), so the nurse must understand current techniques; for example, two types of intrauterine devices are now available, the ParaGard T 380A (copper) and the Mirena hormonal device (levonorgestrel releasing), and once placed they are highly effective (Eisenberg et al., 2015). Laws and policies in some settings restrict nurses and other health care providers from engaging in certain types of counseling, including providing abortion information. Increasing the services offered by funded planning clinics is also necessary. In 2010, 53.6% of publically funded planning clinics offered the full range of FDA-approved methods, and the target for 2020 is 67% (USDHHS, 2015).

TABLE 22-2

Summary of Risks and Noncontraceptive Benefits of Selected Contraceptive Methods

Contraceptive Method	Risks of Use	Noncontraceptive Health Benefits
Oral contraceptives (various formulations: extended, combined, monophasic, biphasic, triphasic, multiphasic, and progestin only)	Thromboembolic disorders, CVA, coronary artery disease especially with smoking, hypertension, diabetes, breast cancer	Reduced risk of functional pelvic inflammation, endometriosis, uterine fibroids, endometrial cancer, ovarian cancer, iron-deficiency anemia, ectopic pregnancy, irregular cycles
Transdermal (contraceptive patch: Ortho Evra)	Similar to oral contraceptives	Easy verification of presence, weekly application
Implants (subdermal rod: Nexplanon)	Similar to oral contraceptives, data more limited	Similar to oral contraceptives, data more limited
Injectable progestin (Depo-Provera)	Prolonged amenorrhea, venous thrombosis, thromboembolism	Bone loss especially in adolescents, unsure of lifetime risk of osteoporosis
Vaginal ring (Nuvaring)	Similar to oral contraceptives, increased risks of cardiovascular events	Vaginal ring hormonal option
Intrauterine contraceptive device (IUD: Mirena)	Bleeding, anemia, difficult removal, PID, ectopic pregnancy, cramping	Reduced risk of anemia, low cost for long term

Emergency contraception (Next Choice, Plan B One-Step)	Nausea, abdominal pain, delay of menses	Not for routine use
Diaphragm	Toxic shock syndrome, allergy to latex or spermicide, urinary tract infection	Reduced risk of vaginitis, cervicitis
Condom	Allergy to rubber, latex, or spermicide	Reduced risk of STI and HIV transmission
Spermicides*	Sensitivity to agent	Antiviral activity against HPV, decreased activity of other STIs, decreased risk of PID
Sponge	Toxic shock syndrome	Decreased activity of STI organisms
Female sterilization (tubal ligation)	Anesthesia, infection, hemorrhage	One-time procedure
Male sterilization (vasectomy)	Complication rates low, reversal may be difficult	One-time procedure

*Often used in combination with other methods.

CVA, Cerebrovascular accident; *HPV*, human papilloma virus; *PID*, pelvic inflammatory disease; *STI*, sexually transmitted infection.

From Hatcher, R. A., Trussell, J., Nelson, A. L., Cates, W., Kowal, D., & Policar, M. (2012). Contraceptive technology (20th ed.). London: Ardent Media; Nelson, A. (2015). Transdermal contraception methods: Today's patches and new options. *Expert Opinion on Pharmacology*, *16*(6), 863–873.

Emergency contraception can reduce the number of unintended pregnancies. In 2010, 81% of family planning clinics offered emergency contraception, and the *Healthy People 2020* target is 87.7%, a 10% increase (USDHHS, 2015). There is a generic two-dose form, Next Choice, and a one-dose form, Plan B One-Step (Teva). The FDA approved over-the-counter use for women of all ages reports that Plan B One-Step is safe and effective. In the United States, progestin-only emergency contraception is available on the shelf without any age restriction (includes Plan B One-Step and generics). Emergency contraception must be started within 3 days of unprotected sex; it works by either altering tubal transport of either sperm or ova, or inhibiting implantation. It will not terminate an existing pregnancy, and it does not provide protection against STIs. The choice to use emergency contraception is frequently made with the partner and may involve complex decision-making centering on responsibility, relationship power, and a woman's right to choose and autonomy over her body (Beaulieu et al., 2011).

Prenatal Care

Access to prenatal care and financing of sufficient care are critical concerns. High-risk and minority women do not receive sufficient prenatal care. Lack of insurance coverage and less-than-adequate referral mechanisms exist. The well-being of mothers and their infants affects the next generation. Racial and ethnic disparities exist, especially for black American infants (USDHHS, 2015). In 2007 the proportion of mothers receiving care during the first trimester of pregnancy was 70.8%; the target in *Healthy People 2020* is 77.6% (USDHHS, 2015). The proportion of mothers receiving early prenatal care needs to increase most in American Indian or Alaska Native and black non-Hispanic mothers (USDHHS, 2015). Another target of *Healthy People 2020,* which reviewed both *early* and *adequate* prenatal care, indicated that as of 2007, 70.5% of pregnant females received adequate care, and the 2020 target hopes to raise this to 77.6% (USDHHS, 2015). The reasons why women do not seek early prenatal care are varied but may include the insensitivity and cultural biases of providers.

Sexually Transmitted Diseases

Young adults aged 20 to 24 years are the group at highest risk of STIs, although the actual rate of infection in this age group has remained fairly stable since 2003 (USDHHS, 2015). Women aged 15 to 19 years and 20 to 24 years have the highest reported rates of chlamydia and gonorrhea respectively (USDHHS, 2015; CDC, 2014). The list of STIs includes HPV infection, *Chlamydia trachomatis* infection, genital herpes, HIV infection, genital mycoplasma infections, cytomegalovirus infection, hepatitis B, and bacterial vaginitis, in addition to the more widely known diseases of syphilis and gonorrhea (Table 22-3). Untreated HPV infection is a risk factor for up to 99% of invasive cervical cancers, and early recognition of HPV infection has decreased cervical cancer incidence and mortality by 70% (Adams & Carnright, 2013). *Chlamydia trachomatis* is very common, and chlamydia screening efforts should focus on all sexually

active nonpregnant and pregnant women aged 24 years or younger (CDC, 2014). The presence of multiple STIs increases the risk of HIV infection. STIs cost billions of dollars in screening, treatment, and reporting. In addition to creating a substantial problem for young adults, STIs impose tremendous demands on health care facilities (USDHHS, 2015). Many cases are unreported and untreated for lack of screening or failure to recognize symptoms. Many young adults do not understand that STIs can be transmitted from oral and anal sex, not just vaginal intercourse. A study sponsored by the CDC found that young adults rarely discussed STIs at home or with partners or close friends; however, young women may look to these intermediary sources if they are worried about having an STI (Friedman & Bloodgood, 2010). Neighborhood structural supports can also be associated with acquisition and incidence of STIs (Ford, 2011; Ford & Browning, 2011). Most of the prevalence statistics on STIs comes from health provider reports; this emphasizes an important nursing role in gathering accurate case information on STIs in the young adult population (Friedman & Bloodgood, 2010).

TABLE 22-3

Summary of Selected Sexually Transmitted Infections

Infections	Causative Agent	Diagnostic Methods	Treatment	Risks or Complications	Nursing Teaching
Viral diseases	Treatment does not eradicate underlying infection				
AIDS	HIV	Enzyme immune assay, Western blot, viral tests	Current recommendations	Opportunistic infections, perinatal transmission	Monitor CD4 T lymphocyte analysis and HIV plasma viral load, monitor men who have sex with men, early pregnancy testing strongly recommended
Hepatitis B	Hepatitis B virus	Hepatitis B antibody test	No specific therapy available	Perinatal transmission	Routine vaccination or vaccine before pregnancy
Genital herpes	Herpes simplex virus	Herpes simplex virus antibody test, culture, viral	Acyclovir at first diagnosis or episode	Urethral stricture, lymph node	Examine partners, abstain from sex while symptomatic

		test		enlargement	
Genital warts	Human papilloma virus	Clinical inspection, colposcopy, biopsy	Podophyllin, trichloroacetic acid, cryotherapy/laser, valacyclovir, famciclovir	Cervical dysplasia, cervical cancer	Offer Gardasil or Cervarix vaccine and counseling, return for treatment as necessary, treat partner
Bacterial/Other STIs					
Gonorrhea	*Neisseria gonorrhoeae*	Culture	Ceftriaxone, cefixime, some strains becoming resistant	PID, infertility, ectopic pregnancy	Monitor antibiotic treatment, examine partner, repeat culture, check for chlamydia
Syphilis	*Treponema pallidum*	Fluorescent antibody tests of lesion or exudates, VDRL, RPR	Benzathine penicillin G	Secondary/late syphilis	Monitor treatment, test and monitor partner
Chlamydia	*Chlamydia trachomatis*	Culture, chlamydia monoclonal antibody test	Azithromycin, doxycycline	Infertility, ectopic pregnancy, urethral scarring, PID, endocervicitis, neonatal infection	Refer partners for evaluation, condoms to prevent future infection
Bacterial vaginosis	*Gardnerella vaginalis*	Clinical criteria, wet mount (clue cells)	Metronidazole (Flagyl)	Asymptomatic infection	Sexual transmission not proven
Trichomoniasis	*Trichomonas vaginalis*	Trich rapid test, culture (protozoa)	Metronidazole (Flagyl)	Recurrence, excoriation of genital area	Use condoms to prevent new infection
Vulvovaginal candidiasis	*Candida albicans,* non–*C. albicans*	Wet mount/potassium hydroxide test (hyphae and spores)	Antifungal medication: butoconazole, miconazole, clotrimazole	Recurrence of disease	Reduce moisture/heat in genital area, recheck in 14 days

PID, pelvic inflammatory disease; *RPR,* rapid plasma reagin test; *VDRL,* Venereal Disease Research Laboratory test.

Human Immunodeficiency Virus

More than 1 million people were estimated to have HIV infection in

the United States (USDHHS, 2015): improved longevity of infected persons and better treatment have made HIV infection more like a chronic disease. Meeting the treatment or prevention needs of this large group of chronically infected persons, especially HIV-positive low-income Americans, has become a priority. An important challenge is to develop more effective strategies to prevent new infections and improved case finding (USDHHS, 2015). In 2010, the White House published a three-pronged HIV/AIDS strategy to reduce the number infected individuals; increase access and care for affected individuals; and reduce HIV health-related disparities. HIV is transmitted by sexual intercourse (oral, vaginal, anal), shared needles, and infected blood. Another less common source of transmission is from the mother to the baby across the placental barrier or through breast milk. The higher level of worry about contracting HIV and other STIs in young adults is correlated with the implementation of risk-reduction behaviors. The incidence of STIs is greatly reduced with proper use of condoms. In *Healthy People 2020,* use of condoms in various age groups surpassed the targets (USDHHS, 2015), and condom use is considered to be increasing. Prevention education is aimed at all high-risk groups, including heterosexuals and men who have sex with men. All sexually active individuals are counseled on the hazards of unprotected sexual activity and on the effective use and limitations of condoms, stressing that they must be used properly and can fail. Condom failures occur at an estimated rate of 10% to 15%; therefore counseling should stress that condom use is not foolproof. Another success is the decline in perinatal transmission. The rates of HIV perinatal transmission are greatly reduced by drug therapy during pregnancy, changes in obstetric practice, and prohibition of breastfeeding in infected mothers. The US Public Health Service highly recommends voluntary testing for HIV and counseling as a part of basic prenatal care (USPSTF, 2015).

The nurse's role in intervening with regard to STIs includes providing treatment, early diagnosis, and education. When an individual is suspected of having an STI, the nurse obtains a complete history, including sexual history, sexual contacts, previous treatment

and test results, any signs or symptoms of a current infection, recent use of antibiotics, and allergic reactions to antibiotics. When treatment is required, the nurse ensures that the person understands the goals of treatment in an attempt to gain cooperation, including follow-up care with partners and adherence to the care plan.

The nurse is an educator not only of the individual but also of the general public (Ford & Browning, 2011). Appropriate health education for the individual with an STI includes the mode of transmission, incubation periods, signs and symptoms, methods of treatment, complications resulting from lack of treatment, and signs of recurrent infections.

Coping–Stress Tolerance Pattern

Assessment of Stress Levels

Stress, the result of forces operating on the individual that disrupt physiological or psychological equilibrium, is an integral part of young adulthood; therefore a comprehensive health assessment should include questions to determine stress levels. Anxiety, nervousness, depression, or somatic complaints are indicators of stress, as are events such as divorce, loss of employment, failure to be promoted, or financial difficulties. The role of the nurse is to listen, offer support, and demonstrate concern. The nurse also suggests referrals to appropriate health providers and support groups.

Achievement-Oriented Stress

Achievement-oriented stress differs from the stress of situational crises in that the stress of an overachiever is derived from internal pressures to succeed as measured by self-defined goals. Among many other stressors, young adults are often engaged in higher education programs at the college or university level. Achievement-oriented stress frequently causes workaholic habits, including loss of sleep and omission of meals. When this behavior becomes extreme, there can be serious physical and emotional consequences, such as nutrition problems or burnout, which, in turn, leads to severe emotional and

physical exhaustion. Workaholic behaviors may not be perceived by the individual and may not be apparent until changes in body functions or behavior occur. Young adults are generally health conscious and willing to alter personal lifestyles and behavior patterns to reduce stress and become healthier.

Suicide and Depression

Suicide is a leading cause of death in the young adult age group. Young adults may be thought of as "young invincibles"; however, they are in an age group exposed to new stressors (Neinstein, 2013). Suicide occurs because many young adults are unable to cope with the pressures of adulthood. For some people, pressure arises when they are dealing with interpersonal conflicts such as marital problems, family discord, or the loss of a close relationship; for others, the precipitating event is a lack of personal resources, unemployment, or dissatisfaction with work or school. Many young adults try to solve their problems before the fatal incident but see no positive solutions; in many cases, a prior suicide attempt was a signal for help.

Suicide rates are higher for men than for women; approximately four to five times as many men as women (18.4 vs. 4.7 deaths per 100,000 population in 2007) take their own lives (US Census Bureau, 2011). However, more women are known to have depressive disorders and to unsuccessfully attempt suicide. Young adults are more likely as a group to attempt suicide than are older individuals, and professionals are more likely to attempt suicide than are nonprofessionals. Suicide is more common among single, widowed, and divorced individuals. Chronically ill young adult males may also be more at risk of depression than young adult females because social support systems are more robust within female relationship networks. Young adults have the lowest rates of health insurance coverage, so a number of these risks can coincide in a "perfect storm" (Neinstein, 2013).

The USPSTF recommends depression screening for adults aged 18 years or older when staff-assisted support is available for adequate diagnosis and treatment. The USPSTF website has a 10-question

depression screening survey that includes the following questions: whether in the last month the young adult has been bothered by little interest or pleasure in doing things, and whether the young adult has felt down, depressed, or hopeless in the last month (USPSTF, 2015). A "no" answer to the questions indicates a negative screening result. The USPSTF does not recommend routine screening for suicide or recommend against it because positive research support for routine screening is not clear.

In 2007, approximately 13 per 100,000 population-specific deaths of individuals between the age of 25 years and the age of 34 years were classified as suicides (US Census Bureau, 2011). Nursing interventions are directed toward identifying behaviors in individuals who may be contemplating suicide. Presuicidal individuals also tend to exhibit impaired reality testing; feelings of hopelessness, helplessness, and rejection; impaired judgment and decision-making; anxiety; weight loss; insomnia; or a radically changed affect. In addition to identifying presuicidal behaviors, the nurse also investigates relationship patterns to determine behaviors that are complicated by feelings of worthlessness and defeat. When the nurse identifies a young adult at risk of a suicide attempt, referrals to other professionals are indicated.

If the health care provider becomes more concerned that the young adult may be at risk of suicide, the following two questions may be asked: "What thoughts have you had about hurting yourself or even killing yourself?" To question further the nurse can ask, "Have you actually done anything to hurt yourself?" (Depression Management Tool Kit, 2009; USPSTF, 2015). Even with education of the public and health care providers about the incidence of suicide in the young adult population, suicide continues to be a major health problem, and annual rates, especially for young men, remain high.

Values-Beliefs Pattern

Young adults enter their 20s with habits, values, and beliefs acquired during childhood and adolescence. Many acquired habits foster continuance of practices that are hazardous to health and well-being in later life. Prevention is directed toward altering value and belief

patterns that encourage poor health practices, and reorienting them toward those that support optimal health behaviors. Nursing care is more effective when the nurse can describe, discriminate, identify, and align value and belief patterns consistent with practices known to maximize health.

Values Involved in Parenting

Parenthood is envisioned as an important developmental stage by most young adults; therefore health-promotion and health-protection activities to ensure healthy offspring are crucial (see the case study and care plan at the end of this chapter). **Genetic impairments**, or **congenital defects** caused by abnormal chromosomes, are responsible for 4% to 6% of perinatal deaths (Perry et al., 2013). Tests are available for approximately 200 genetic diseases (Perry et al., 2013). Most of the genetic testing offered is for single-gene impairment to mothers and fathers who have a family history of genetic disease. Young adults with a genetic disease must make many important decisions; predicting the transmission of the disease to potential offspring is essential to future planning.

Values Regarding Prenatal Diagnosis and Genetic Impairment

Extensive prenatal diagnostic procedures have been available since the mid-1960s. This capability has enabled the identification of high-risk pregnancies and requires the cooperation and education of childbearing women and their partners, both of whom must provide accurate family health and obstetrical histories and comply with suggested screening and follow-up measures. Decisions about the advisability of reproduction are based on current information on genetics and known deleterious genetic factors.

The finding of a malformed or genetically impaired fetus may result in a parental decision to terminate the pregnancy. Theological and political debates in addition to legislative mandates have greatly influenced family control over many of these decisions. Genetic

counseling is an important nursing intervention for young adults. A genetic specialist gives technical explanations of genetic disorders; however, nurses have a strong supportive role in helping young adults decide whether to have children or to carry through a pregnancy that is at risk.

Environmental Processes

Physical Agents

Ethnicity, Race, and Culture

The young adult whose ethnic background is different from that of the dominant culture may encounter prejudice and discrimination, which can occur because of differences in race, creed, language, attitudes, values, preferences, or behaviors. The young adult is susceptible to these prejudices at work, at school, in health care delivery systems, and in the community.

Race and ethnicity are closely connected to educational and work-related decisions, which subsequently affect the choice of residence. Many minority families live in substandard housing or crowded living spaces. A lifestyle on the margins, when combined with insufficient economic resources, frequently affects health. Poverty is more common among black families, which often leads to unmet basic needs of food, clothing, and housing and, in turn, leads to decreased regard for health needs.

Accidents

Injuries are the leading cause of death in young adults and individuals younger than 44 years (USDHHS, 2015). Motor vehicle accidents cause more fatalities than all other causes of death combined. Reducing speed limits contributes to lower fatality rates. Most states have seat belt laws, and all states have seat belt requirements for children. All individuals in the car need to use seat belts because an unrestrained occupant can cause harm to another passenger in a crash. In 2013, 87% of motor vehicle drivers and front seat occupants used seat belts, and the target for 2020 is 92.4% (USDHHS, 2015). Distracted driving, texting while driving, and cell phone use are the cause of many motor vehicle crashes. Most states have enacted “hand-free” or Bluetooth wireless audio legislation that limits the use of hand-held car cell

phones. The continued high incidence of vehicle accidents in the young adult age group is related to accessibility of cars to young adults and peer pressure on driving behavior; reckless driving and driving under the influence of alcohol and drugs are now viewed as closely connected to violent and abusive behavior. A number of states have specific rules that limit cell phone use by drivers younger than 18 years.

Accident-prevention education, long considered appropriate for young children, is an important part of young adult instruction. Most young licensed drivers have participated in driver education courses, and a number of states have adopted progressive licensing programs. A number of states have "graduated driver licensing" programs (Trust for America's Health & Robert Wood Johnson Foundation, 2015), which have been shown to reduce younger driver crash rates by 8% to 14%. In 2015, 46 states had banned texting while driving, and two additional states ban texting by novice drivers (National Institutes of Health, 2014a). The young adult must understand the potentially fatal consequences of aggressive tendencies or thoughtless risk-taking. When young adults are encouraged to reflect on the consequences of their actions, they tend to be more willing to control and change unsafe driving behaviors.

Biological Agents

Noise Pollution

Young adults are exposed to high levels of noise in occupational and recreational settings (concerts and nightclubs). Long-term exposure to loud noise is directly related to impaired hearing and can increase irritability and stress. Young adults can be exposed to noises in the work setting from industrial machinery and equipment. Although industrial exposure can be difficult to mitigate, many young adults worsen the situation through recreational exposure, by listening to music or music videos at excessively high decibel levels. Ear protection is necessary to prevent hearing disability. Recognition of hazards and corresponding appropriate preventive education are

early nursing strategies for decreasing excessive noise exposure.

Air Pollution

Motor vehicles are the largest source of air pollution; vehicles release tons of particles and noxious gases each year, most of which is either carbon monoxide or hydrocarbons. Carbon monoxide in high concentrations is deadly; in lower concentrations, it causes headaches, dizziness, and heart palpitations. In sunlight and low-lying areas, automobile exhaust becomes photochemical smog that contains ozone, which irritates the eyes and the respiratory tract. Although air pollution is not a problem only for young adults, they frequently work in dirty, entry-level jobs in industrial settings and may be among the age group that is most affected.

Occupational Hazards and Stressors

Occupational hazards pose a threat of illness, injury, or death in all age groups, and occupational safety standards have contributed greatly to the reduction of work-related accidents. The Occupational Safety and Health Act (1970) has resulted in the improvement of work conditions, along with the provision of health care facilities, in many companies.

Young adults should not be allowed to work in certain industrial settings without vocational training to reduce hazards. Young adults frequently want a challenge and high wages; therefore they work in hazardous jobs—for example, on offshore drilling rigs, on high bridges, or in nuclear plants. Because of their age, physical stamina, and agility, young adults are suitable candidates for positions that require extreme physical abilities. Occupational training should include education about personal exposure risks, identification of work-related hazards, and identification of situations in which the severity of accidents is connected to personal behaviors or habits. For example, drivers of heavy construction machinery should be particularly observant, avoid reckless behaviors, and avoid fast driving. Working women who are pregnant can expose their fetuses

to industrial chemicals. Proper evaluation and temporary reassignment may be necessary.

Occupational preventive intervention requires that known work hazards and risks be identified early. Health histories should include questions about the place of work, type of work, and young adults' understanding of the risks associated with their occupations. Occupational risk and health are closely related; stress associated with work, the use of alcohol or drugs, and a negative attitude toward work are predictive of occupational injuries. Job counseling aimed at changing the nature of employment can be an appropriate referral for some people with health conditions. Nurses in occupational settings can provide periodic health assessments, updates of the health history, and counseling.

Chemical Agents

Drug Use

Misuse of drugs, a major risk for young adults, is associated with injury, disability, violence, homicide, and suicide and is related to social problems (criminal behaviors and maladjustment to accepted norms) (Neinstein, 2013). Drug abuse, including inappropriate use of prescription drugs (National Institutes of Health, 2014b), may be closely related to an inability to cope appropriately with adult responsibilities. Physical health problems associated with drug misuse account for more than 50% of the major acute and chronic problems of young adults. Heroin users have increased mortality rates because of overdosage or chronic disability associated with hepatitis infections. Drug use is an independent risk factor involved in HIV infections (USDHHS, 2015).

Misuse and overuse of drugs, including prescription drugs and opioids, is widespread. Heroin use more than doubled among young adults aged 18 to 25 years in the past decade, and death from heroin use is now overtaking deaths from motor vehicles in many states (CDC, 2015b; Neinstein, 2013; Trust for America's Health & Robert Wood Johnson Foundation, 2015). Young adults are more likely to use

illicit drugs and abuse prescription pain relievers (Neinstein, 2013). In addition, young adult males may also use performance-enhancing drugs such as anabolic steroids. Drug interactions can be fatal. Preventive education should focus on cautious drug use, healthier sports, and exercise. Nursing activities include preventive strategies to curb the problem of drug misuse. Distribution of current drug literature, early treatment of complications, and information regarding drug treatment centers are only part of the answer. Some states have drug monitoring enforcement of prescription drugs by providers, and more widespread legislation is recommended (Trust for America's Health & Robert Wood Johnson Foundation, 2015). Nursing efforts and political activities aimed at increasing personal prescribing awareness and altering drug-taking attitudes and behaviors are of critical importance (Box 22-6: Genomics).

Box 22-6

Genomics

Pharmacogenetics: Genomics and Personalized Medicine

Different genetic types tend to metabolize drugs differently, have different binding receptors, or have different environmental influences that change the utilization and uptake. This field of study is called pharmacogenetics. Early clues to variation in drug response were seen in comparisons of populations from different racial and ethnic backgrounds, so there are important cultural awareness implications of these avenues of study. DNA (nucleotide) gene variations are known as single nucleotide polymorphisms (SNPs) and are caused by the substitution of one nucleotide base for another. When these SNPs direct liver metabolic enzymes, the polymorphism or form of the gene inherited causes differences in drug metabolism.

In many ways, gene selection had positive effects on evolution and favored the chances of a population to survive. For example, sickle

cell trait developed through selection factors that favored resistance to malaria. Similarly, gene selection factors also favored the prevalence of glucose 6-phosphate dehydrogenase deficiency, which also provides resistance to malaria but causes drug-related red blood cell hemolysis. In related studies of warfarin response, ethnic differences were shown to affect bioavailability and distribution, which could be controlled through more precise clinical management and dosage regulation. Warfarin dosing is significantly altered by polymorphisms in the liver and enzymes affecting vitamin K synthesis.

In studies of people with hypertension, black individuals responded with a greater decrease in systolic pressure in response to thiazide diuretics (hydrochlorothiazide) and calcium channel blockers. Black individuals have a blunted response to alpha-blockers, which can be increased by addition of a diuretic. Many black individuals have renin sensitivity, which would have favored survival in warmer climates.

The situation in Asians appears to be the exact opposite. In a study of the effectiveness of propranolol in Chinese and white men, the Chinese men had at least twice as much sensitivity as did the white men to propranolol administered at several different dosages. Studies indicate that Asians are more sensitive to alcohol and its drug effects than are whites. The most outstanding difference is in the amount of facial flushing, which was experienced by a substantial percentage of Asians compared with whites. The enzyme alcohol dehydrogenase is reported to be absent in approximately half of Asians.

These examples suggest that nurses should be much more attuned to potential genetic variations that alter drug metabolism and effectiveness. In individuals who do not respond to certain drugs as expected, the nurse may consider whether this might be related to constitutional factors within the person's genomic makeup. Pharmacogenetic research also invites rethinking of managed care practices that restrict diversity of drug use with prescribed drug formulary listings.

From Kudzma, E., & Carey, E. (2009). Pharmacogenomics: Personalizing drug response.

Alcohol Use

Alcohol-related accidents among individuals aged 15 to 24 years continue to be a leading cause of preventable morbidity, disability, and death. Heavy alcohol use, that is, consumption of five or more drinks on at least one occasion within a month, is more common in 18- to 24-year-olds than it is for younger or older adults (Neinstein, 2013; USDHHS, 2015). Raising the legal drinking age to 21 years reduces not only deaths and injuries connected to motor vehicle accidents but also homicides and other violent deaths. All 50 states have now set a maximum blood alcohol concentration of 0.08% for driving while intoxicated enforcement and prosecution. Alcohol abuse is directly related to chronic conditions such as cirrhosis. Modifying alcohol consumption in young adults can decrease the frequency of chronic and disabling conditions in later life.

Binge alcohol consumption is increasing in the young adult population. In 2008, 27% of young adults aged 18 years or older reported that they have engaged in **binge drinking** in the previous 30 days (USDHHS, 2015). In the 18- to 22-year-old age group, binge drinking is higher among full-time college students than those not enrolled full-time (Neinstein, 2013). In a 2004–2006 study, approximately 7% of young military veterans had a substance abuse problem (USDHHS, 2015). This is important as many young adult men have participated in military operations. Although young adults may drink less frequently than older adults, there is a tendency to consume larger amounts of alcohol at a time; the tendency is toward binge drinking, which causes increased loss of control and is related to an additional risk of automobile crashes. Teens with work schedules of more than 10 hours per week are more often involved in heavy or binge drinking, or both. Working longer hours increases the money available to purchase alcohol and exposes the teen to older adults who drink.

Tobacco Use

Smoking is a leading cause of preventable death in the United States; therefore smoking cessation is the single most important counseling topic for all people because of its potential to lower the risk of contracting many preventable diseases. More than one-third of current smokers aged 18 to 24 years started smoking before the age of 16 years. Cigarette smoking rates among people aged 18 years or older continued to decline from the 1998 baseline of 24% to a 2013 level of 18.3% (USDHHS, 2015). Whereas general smoking rates are declining, younger adults are more likely than older adults to try or use e-cigarettes; the use of e-cigarettes was highest in current and recent former smokers (Schoenborn & Gindi, 2015). An ancillary goal of *Healthy People 2020* to keep the smoking rate low is to increase tobacco cessation counseling in office-based ambulatory settings and hospital ambulatory settings. To augment antismoking efforts, tobacco advertising and sales have been limited, and the federal excise tax has been increased.

Individuals employed in high-risk occupations (e.g., mining, construction) are informed of the synergistic relationship between smoking and other environmental exposures, including exposure to asbestos, coal dust, and radiation. Fear tactics, nagging, preaching, and threats are generally ineffective in convincing people to stop smoking. A major barrier to smoking cessation is the presence of other smokers, particularly in situations where alcohol is also being consumed.

State enforcement of no-smoking policies is important. Between 2005 and 2009, lung cancer death rates declined in states with strong tobacco control enforcement and increased in states where tobacco control measures were weak. Tobacco control measures are strongly correlated with smoking cessation rates of young adults (Henley, et al., 2014). Nurses are familiar with the antismoking resources in their communities, enabling them to make the appropriate referrals.

Carcinogens

Young adults can be exposed to environmental carcinogens in their work settings or through unhealthy practices such as having multiple

sexual partners. In the work setting, environmental regulations have limited exposure to some hazardous chemicals, but the long-term effects on health of exposure to many industrial chemicals remains unknown. In health care, latex, long considered inert and safe, has now been shown to cause long-term immune system disease in some nurses exposed to it (or the chemicals that bind it) in surgical gloves.

Determinants of Health

Social Factors and Environment

Neighborhood Resources

The environment of the community strongly influences the well-being of the young adult and sets the standard for the health of people and families living within a neighborhood. Neighbors can be an excellent source of support, which can be especially important to a young mother who does not have immediate family nearby. Nurses working in community settings facilitate the contact of individuals with common interests through community and religious activities and support groups. Community resources for exercise and recreation can make important contributions to the young adult's physical and emotional health. When these resources are available, the young adult can have the opportunity to exercise and release stress in a positive fashion.

Levels of Policy Making and Health

Young adults are one of the major political constituencies in the United States, as seen in their involvement in recent presidential elections; they support many causes and have the time and energy to publicize issues related to the common good. Some of these issues involve unemployment, college debt, sustainability, pollution, the environment, nuclear energy, and war. Relative to health, predominant issues have involved housing and health care in neighborhoods and rural areas and health, agricultural, and sanitation concerns in foreign countries. Through these efforts, young adults can influence and improve living conditions for future generations.

One of the young adult's age-related tasks is to choose and develop a lifelong career. This choice is directly related to economic factors; young adults want satisfying occupations that also yield adequate economic returns. To manage financially and maintain a lifestyle in

which personal needs can be met, young adults may elect to have fewer children. Caring for aging parents can also cause physical, psychosocial, spiritual, and economic stress.

Although goals differ greatly among young adult couples, they are generally concerned with acquiring material comforts; the desire for housing, transportation, clothing, or recreation generally necessitates that both partners are employed to meet financial obligations. This desire necessitates the changing of roles and the sharing of responsibilities, and open communication becomes a crucial component.

New career opportunities and the economic expansion in the United States during the 1990s allowed young adults obtaining first jobs more career choices. The growing technology industry provided employment in a wide variety of occupations and start-up companies. Work styles within these companies tend to be different from those in the traditional workplace, including an expectation of longer and more fluid workdays. Internet-based companies provide young adults with jobs that have the potential to give them rapid financial rewards at the cost of long-term job stability. Since 2012 the employment rate of young adults aged 18 to 24 years (54%) has been at its lowest since data were collected in 1948. Between 2008–2011, employed young adults also experienced more of a decline in weekly paychecks (decline of 6%) than any other employed age group (Pew Research Center, 2012). Because of the high cost of housing, many young adults have multiple roommates, creating additional demands and health risks. Some continue to live with their parents (Burn & Szoeke, 2016). Some young adults are interested in giving back to society by taking employment at lower salaries in nonprofit agencies involved in education and social issues, such as Habitat for Humanity, and going abroad in the Peace Corps to promote human rights in countries where such rights are nonexistent.

For many young adult couples, problems of unemployment for one or both, different careers, friends, and differing maturity levels place additional strains on their relationship. These circumstances can provide a basis for domestic difficulty. Domestic arguments can

precede family disruption, leading to marital separation or divorce. In addition to the emotional strain placed on family members, domestic arguments can result in aggressive acts of abuse and personal injury. Young adults can also be faced with decisions about day care facilities; the couple or mother may need support to resolve guilt feelings related to the separation from the child. Some young adults may also bear responsibilities for caring for aging parents or relatives.

Lifestyles may also include living arrangements with individuals of the same sex or the opposite sex. Although these lifestyles are becoming more acceptable in today's society, attitudes toward varied lifestyles contribute pressures that lead to further stress and uncertainty.

Health Services/Delivery System

The availability of health services is important. Improving health services generally means finding usual and continuing sources of primary/preventive care. Economic realities, however, influence the effectiveness of resources, particularly for the young adult who lives in an economically depressed area. In some communities, health services are lacking or, when available, are not culturally sensitive or adapted to the customs and beliefs of the people who are served. Access to public transportation can be a critical problem, affecting the ability of the young adult to keep appointments. Young adults have the fewest outpatient health care visits and the highest number of emergency department visits (Neinstein, 2013). Young adults aged 18 to 24 years are the least likely of any age group to have a usual source of care (Hing & Albert, 2016); thus a target of *Healthy People 2020* is to increase the proportion of young adults with a usual primary care provider (USDHHS, 2015). Gaps in health care insurance coverage that occur between the end of schooling and the attainment of full employment can reduce the access of young adults to primary care. The Affordable Care Act, passed in 2010 (https://www.hhs.gov/healthcare/), mandates coverage for young adults up to the age of 26 years within family health insurance coverage. This act has decreased the young adult uninsured rate

somewhat from 28% to 24% (Neinstein, 2013) and has maintained millions of young adults insured on the family health plans (Sommers et al., 2013).

Health delivery methods in the United States are based primarily on Western belief systems, which tend to be rigid in their applications. For example, women seeking birth control information and prescriptions are expected to use health clinics and adhere to a set schedule of return visits. The most common insurance claims for young adult women are associated with gynecology and obstetrics (Neinstein, 2013). Because health care provider systems have removed many traditional barriers once assumed to be responsible for poor utilization of services by low-income or minority groups (insurance, location and scheduling), nonattendance at scheduled clinic visits is frequently interpreted as nonadherence. Nurses need to be able to identify health practices and health system gaps that are barriers to care and harmful to people.

Nursing comprises the largest group of professionals within the US health care system. However, nurses may not be able to deliver care optimally within changing health care settings because of barriers to practice and ineffective workforce planning, data, and information infrastructure. A widely circulated report from the Institute of Medicine (2010) noted that the nursing profession cannot contribute optimally unless nurses fully participate in team planning and health care redesign with physicians and other health care professionals. In addition, business, government, health delivery agencies, and the insurance industry must all participate in a newly designed health care system that provides accessible, affordable quality care, leading to increases in measurable health outcomes (Institute of Medicine, 2010) (see the case study and care plan at the end of this chapter).

Nursing Application

Young adulthood is generally considered to be the most healthful period of life. In terms of physical changes, growth is complete by this stage. The physical abilities of the young adult are in peak condition, so the goals of the nurse are aimed at maintaining optimal physical condition, encouraging healthy habits, screening individuals for disease, and treating illnesses.

Preventive care is recommended to young adults in the form of screening and preventive care visits (Hing & Albert, 2016). Health examinations at recommended intervals are a crucial component of screening individuals for potential health concerns and providing education about measures to avoid disease and disability. Women are taught about breast self-examinations, whereas testicular self-examinations are taught to men with use of photos, models, and return demonstration.

It is necessary to screen individuals for cardiovascular conditions after the age of 25 years as well as to provide education about risk factor modification. Intervention efforts should reflect diversion of age, sex, ethnicity, and socioeconomic status. As the nurse obtains an assessment of the individual and family history, the necessity of further screening, education, or monitoring is determined. Elements of education include smoking cessation and dietary modifications.

Young adults are encouraged to engage in physical activity and muscle-strengthening exercise. Lack of time or lack of access may be barriers to increased physical activity. The nurse working with the young adult population should consider implementing work site wellness programs. Group fitness or weight loss programs can be an effective means of promoting wellness at work while increasing employee satisfaction and productivity. Some workforce programs use incentive systems where points are awarded for the achievement of particular milestones. Once a set level of points is reached, the employee is given a reward in the form of gift cards or movie tickets. These types of programs are often effective for smoking cessation,

weight loss, and exercise. In addition, some companies encourage the formation of facility-sponsored sports teams for charities or sports such as bowling leagues, softball teams, or a running club. This encourages camaraderie among colleagues and increases participation for people who respond well to group motivation. Nonworking young adults looking for a group fitness or sports program should be directed to resources within the community via Internet research.

The nurse working with young adults provides education about skin cancer risk, the need for adequate sunscreen, and signs and symptoms of skin cancer. Safety education is provided about recreational and sports-related injuries and how to prevent them. Additional education is required for young adult females. The nurse may be in a position of providing counseling or referrals for contraception, prenatal care, STIs, and HIV infection. It is imperative that women receive preconceptional and early prenatal care to maintain optimal health for themselves and the unborn child.

The nurse working with the young adult population often becomes a counselor. It is important to assess stressors as prolonged stress, anxiety, or depression can negatively affect the health of the individual. Stressors may be related to relationships, divorce, employment, layoffs, or financial concerns. The nurse listens, offers support and concern, and provides the individual or family with resources or support groups specific to the stressor.

Case Study

Preparing for Childbearing: Kirsten

Kirsten is a healthy 22-year-old whose favorite sport is running. Most of the time she runs outside, but she also uses gym treadmills. Since this spring, Kirsten has believed that her breathing capacity is diminishing and her levels of energy are decreasing. During her period these symptoms appear to worsen. Last week, while running up a rather steep course, Kirsten became much weaker, dizzier, and more fatigued than usual, and her best friend and running partner

recommended that she make a physician's appointment for a physical examination. Kirsten's running partner also noted that she has appeared pale lately.

In the physician's office, Kirsten is noted to have a normal temperature, elevated heart and respiratory rates, and a blood pressure of 90/60 mmHg. Kirsten's description of her period is that it tends to be heavy and has been this way for 5 years. For muscle aches and pains caused by running, she usually takes two aspirin tablets every 3 to 4 hours for as long as 7 days. When her running increases during the summer, she takes aspirin or ibuprofen continually for 2 to 3 months. Diagnostic testing indicates that her hemoglobin level is 7 g/dL, and her red blood cells are pale and small. Kirsten has been in a long-term relationship for several years, her wedding is in several months, and there has been discussion of preconceptional health planning and future children.

Reflective Questions

- What common health alteration in young adult women is most likely for Kirsten?
- What contributing factors place Kirsten at risk?
- What lifestyle modifications can Kirsten implement to decrease her risk?

Care Plan

Preparation for Childbearing: Kirsten

***NURSING DIAGNOSIS: Health-seeking behaviors related to preconceptional assessment and preparation for childbearing**

Defining Characteristics

- Expressed desire to improve overall health to prepare for

childbearing

- Expressed thoughts about planning for pregnancy soon
- Desire to improve nutritional status before childbearing
- Desire to improve nutritional intake of essential vitamins and minerals (iron and calcium)
- Plan to take a multivitamin each day
- Plan to limit consumption of foods high in sodium and fat
- Plan to limit alcohol consumption
- Plan for exercise program to increase stamina and flexibility
- Seeks physical examination to rule out problems that might negatively affect pregnancy
- Seeks information on pregnancy risk factors (biophysical, psychosocial, sociodemographic, and environmental)

Related Factors

- Expressed desire to improve the quality of relationship with husband or partner
- Desire to attend education classes to improve knowledge of childbearing and positive health practices
- Plan for room or housing for a young couple that might accommodate children in the future
- Plan for employment arrangements that accommodate child care

Expected Outcomes

- Increase in indices of well-being in person
- Healthy pregnancy and future child
- Increase in self-confidence and awareness preparation for childbearing
- Management of pregnancy risk factors before becoming pregnant
- Making the person aware of resources available for pregnancy and child care

Interventions

- Assess current level of wellness regarding preparation for childbearing.
- Identify community resources that provide information regarding preconceptional planning and preparation.
- Identify primary health provider, midwife, or obstetrician, and hospitals with delivery services.
- Assess biophysical risk factors (genetic/genomic disorders, nutrition problems, and current medical problems).
- Assess for history of pregnancy loss.
- Test for blood type and Rh factor.
- Screen for STI, tuberculosis, rubella titer, sickle cell trait.
- Review immunization status.
- Assess need to augment diet, particularly to increase intake of calcium and iron.
- Take a multivitamin daily.

- Assess for psychosocial risk factors (mental problems; use of drugs, alcohol, and caffeine; and smoking).
- Counsel to avoid alcohol consumption.
- Assess for possible sociodemographic risk factors (poverty, first pregnancy risks of dystocia or pregnancy-induced hypertension, residence [rural or urban], and ethnicity).
- Assess for environmental risks (exposures to chemicals, drugs, pesticides, pollution, smoke, stress, and radiation).
- Assess current employment situation.
- Identify child care arrangements.

[*]NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

From Gordon, M. (2016). Manual of nursing diagnosis (13th ed.). Burlington, MA: Jones & Bartlett Learning.

Summary

Nurses promote health care measures and behaviors at all places where young adults come into contact with the health care delivery system. In community colleges and university settings, efforts can be directed toward health-education curricula with an emphasis on implementation of positive health behaviors, use of appropriate social networking skills, establishment of peer counseling groups, and better utilization of sports and exercise facilities. Workshops on alcoholism, substance abuse, sports or exercise, mental health and self-expression, relationships, and various aspects of sexual care are effective in college and graduate school populations. At the work site, the occupational nurse is involved with employee counseling, blood pressure monitoring and treatment, exercise recommendations, smoking reduction, cafeteria nutrition management, and stress-reduction techniques. Insurance coverage as part of the Affordable Care Act has assisted young adults to have significant gains in health insurance and access to care (Sommers et al., 2013). Preventive care, mental health, dental health, and maternity and infertility benefits are being analyzed and increased when necessary. Young adults are generally healthy, which challenges the nurse to be even more creative, sensitive, and insightful in implementing care for individuals within this age group.

Middle-Aged Adult

Maureen Murphy

OBJECTIVES

After completing this chapter, the reader will be able to:

- Name three psychosocial and spiritual changes that frequently occur during middle age.
- Explain the normal biological changes that occur as a result of the aging process.
- Identify the major causes of death in the middle-aged adult.
- Describe frequently occurring health patterns of middle-aged adults.
- Discuss the unique health problems related to the occupations of the adult between age 35 years and age 65 years.
- Analyze the influence of psychosocial stressors on the middle-aged adult and the ways the individual's culture and occupation can affect these stressors.

KEY TERMS

Advance directive

Body mass index

Calcium

Cardiac output

Cataract

Constipation

Degenerative joint disease
Durable power of attorney
Empty nest syndrome
Functional aerobic capacity
Generativity versus stagnation
Gingivitis
Glaucoma
Health care agent
High blood pressure
Kyphosis
Living will
Macular degeneration
Menopause
Midlife crisis
Obesity
Osteoarthritis
Osteopenia
Osteoporosis
Overweight
Perimenopause
Periodontitis
Presbycusis
Presbyopia
Sleep disorders
Vitamin D

Think About It

The "Sandwich Generation"

Charlie Shelton is 48 years old and has been in excellent health. He operates heavy machinery for a construction team that clears environmentally polluted sites in an inner city. These sites are known to be contaminated (lead, mercury, other chemicals), so he visits the occupational health nurse, who supervises intermittent blood testing and physical examinations. He has never smoked and tries to follow the best health advice. He has two children (aged 15 and 18 years). His wife Sarah was working as a licensed practical nurse in a skilled nursing facility until she injured her back and is now receiving disability insurance payments. The elder child plans to enter college next fall, but the Sheltons wonder how they will afford and manage this. Sarah is also the sole caretaker of her mother, who is 80 years old and is in need of increasing assistance. Although Charlie and Sarah worked hard and saved money all their lives, they are worried about college costs, funding an eventual retirement, and the cost of care for Sarah's mother. In addition, Sarah's injury has made them far more conscious about workplace hazards and exposures. The occupational health nurse sees Charlie to assess his physical health; she is also a source for additional referral and support.

- What types of health care providers and referrals are needed by the Sheltons?
- What can health care providers do to guide and support the Sheltons during this stressful time?
- What other health-promotion and wellness strategies might be suggested and implemented to help them?
- What community organizations might the health care provider recommend to meet the needs of this family?
- What responsibilities do health care providers and policymakers have to provide health promotion to middle-aged adults?

An excellent resource for these questions that includes national demonstrations of small work site health programs may be found at CDC Workplace Health Promotion.

http://www.cdc.gov/workplacehealthpromotion/.

During their midlife years, many adults experience expanded responsibilities and increased productivity. In most cases, there is a concomitant increased sense of accomplishment. Middle adulthood spans a 30-year interval between 35 and 65 years of age. Within this age interval, significant biological, physiological, social, psychological, and spiritual changes occur. Vital statistics reports published by the Centers for Disease Control and Prevention (CDC) divide the middle-aged adult into three categories for ease of describing mortality and morbidity data. These are 35 to 44 years, 45 to 54 years, and 55 to 65 years. This age group (30-year span) comprises nearly 40% of the population of the United States (US Census Bureau, 2012).

Many changes related to aging and health that occur during this time frame will be discussed in this chapter. Health promotion addresses choices in behavior and practices that optimize health and well-being for the adult in midlife. This concept is the central focus of the presentation of materials and related figures and study aids.

An examination of the gains achieved for *Healthy People 2010* will be compared with the goals and objectives for *Healthy People 2020*. Along with analysis of these findings, the role of nurses will be interwoven throughout the text. Nurses are integral to the health of the American people, and hence to fostering health promotion and health maintenance.

Biology and Genetics

Although their onset differs, biological changes come to the forefront during the middle years, affecting most body systems. The hair of the adult begins to thin and turn gray. The skin's moisture and turgor decrease, and with the loss of subcutaneous fat, wrinkling occurs. Excessive sun exposure through the years makes some changes more pronounced, especially increased coarseness of facial features.

Fat deposition increases during these years often with concomitant increases in weight. Body height decreases as a result of decreased bone density and mass. This combination of changes results in increased body mass index (BMI). The body contour changes as love handles and saddlebags appear. Sedentary lifestyles and unchanged dietary habits contribute considerably to these changes.

The inactive lifestyle is further compromised by a decrease in energy; “I'm not as young as I used to be” is a common remark. This proclamation is legitimate because the capacity for physical work actually decreases. As **functional aerobic capacity** decreases, there is a resulting decrease in **cardiac output**. For individuals who maintain regular exercise programs that provide stretching and strengthening of skeletal muscle, cardiac output remains essentially undiminished for many years.

In the musculoskeletal system, bone density and mass progressively decrease. When 55-year-old adults say that they were 1 inch taller when they were 18 years of age, the observation is likely to be true. A 1- to 4-inch (2.5- to 10-cm) loss in height occurs as a person ages; thinning of the intervertebral disks accounts for approximately 1 inch. However, dramatic losses in height (more than 4 inches) can occur with thoracic **kyphosis**, an angulation of the posterior spine (commonly known as *hunchback*). The wear and tear on joints predisposes the adult to **degenerative joint disease**, deterioration of the joint(s), with more frequent painful backaches. The general decrease in muscle tone, categorized by many as *flab,* reduces physical agility.

Degenerative joint disease, specifically **osteoarthritis**, has its peak onset in middle age and can greatly influence activity and endurance, which impacts employment. Most frequently the knees and hands, followed by the hips, spine, shoulders, and ankles, are involved. *Healthy People 2010 Final Review* identified two objectives related to arthritis, osteoporosis, and chronic back pain as having moved toward their target attainments: activity limitations attributable to chronic back pain and weight reduction counseling for adults with arthritis. Only one objective exceeded its target by 300%: prevalence of osteoporosis (CDC, 2012).

Osteopenia is a condition of subnormally mineralized bone, usually as a result of a rate of bone lysis that exceeds the rate of bone matrix synthesis. **Osteoporosis** is a disorder characterized by abnormal loss of bone density and deterioration of bone tissue, with an increased fracture risk. It occurs most frequently in postmenopausal women who have fair complexions and are small, in sedentary individuals, and in people using corticosteroids on a long-term basis. Furthermore, osteoporosis increases with age.

The functional capacity of all organ systems generally decreases. For example, in the gastrointestinal tract, the following chain of events occurs: decreased metabolism leads to less enzyme production, resulting in lower hydrochloric acid levels, which decreases tone in the large intestine. As a result, the middle-aged adult may experience acid indigestion with increased belching.

When the adult leads a sedentary lifestyle, the effects of the diminished motility through the gastrointestinal tract can be more pronounced. It is well known that Americans eat more refined foods (foods that are low in bulk) than residents of third world nations. A low-bulk diet can contribute to the problem of **constipation**, a change in bowel habits characterized by decreased frequency or passage of hard, drier stools and difficult defecation, and is believed to be a primary contributor to the increased incidence of colon cancer in the United States. Between age 25 years and age 85 years, a 35% loss of nephron units occurs. The remaining nephrons increase in size and undergo degenerative changes. The entire weight of the kidneys

decreases. Because blood supply is also diminished, the glomerular filtration rate is decreased by nearly half.

Significant changes occur in the cardiovascular system as the blood vessels lose elasticity and become thicker. This process predisposes middle-aged adults to coronary artery disease, hypertension, myocardial infarctions, and strokes. Heart disease is the second leading cause of death in middle-aged adults (Heron, 2012).

Menopause is the cessation of menses. It is an expected physiological change related to aging, and it marks the end of a woman's reproductive function. Menopause is determined retrospectively after cessation of menses for 12 consecutive months. In North America the median age for menopause is 50.5 to 51.4 years (Palacious et al., 2010). Women now expect to live one-third of their lives after menopause. A great deal more must be learned about what causes many of the symptoms that occur in menopause. Sheehy (1993) conducted interviews of 100 women from their mid-40s to their 60s and also interviewed 75 physicians and other experts. Her analysis showed that many of these people felt there was a renewed sexual vitality and surge of mental energy for menopausal women. She characterized menopause as a gateway to a second adulthood. Northrup (2012) and King and colleagues (2013) propose that many women make menopause a time of personal inventiveness while gradually adapting to the many expected biological, psychological, social, and spiritual changes of menopause. During menopause, production of ovarian estrogen and progesterone ceases; the remaining estrogen is produced by the adrenal glands. As a result of the diminished estrogen level, a woman's secondary sex characteristics regress, evident as, for example, loss of pubic hair and decrease in breast size. The female reproductive organs shrink, and vaginal secretions decrease, requiring additional lubrication.

As men approach the end of the middle years, they experience changes in their sexual response cycle as testosterone levels plateau and then decrease. The testes undergo degenerative changes, the number of viable spermatozoa diminishes, and the volume and viscosity of semen decrease. In men, sexual energy gradually declines;

achieving an erection takes longer, but it is sustained longer. Stress, however, can significantly diminish function (Pines, 2011).

Life Expectancy and Mortality Rates

In the last decade (2001–10), life expectancy increased for all groups of Americans in the middle adult years. Across the 30-year age span, there was a decrease in mortality for all racial and ethnic groups, with the most significant decreases noted between age 35 years and age 44 years. Life expectancies for American men and women are now at record highs: 81.1 years for women and 76.3 years for men (Arias, 2015).

The leading causes of death during middle adulthood are heart disease, cancer, and accidents (National Vital Statistics, 2016). Box 23-1 shows a breakdown for each decile or 10-year interval for the middle-aged adult. Reducing disabilities and deaths from these chronic conditions are national health-promotion and disease-prevention objectives.

Box 23-1

Leading Causes of Death in Middle-Aged Adults

Age 35 to 44 Years

- Unintentional injuries (40.2 deaths per 100,000 population)
- Malignant neoplasms (31.9 deaths per 100,000 population)
- Heart disease (28.3 deaths per 100,000 population)

Age 45 to 54 Years

- Malignant neoplasms (116.3 deaths per 100,000 population)

- Heart disease (88.0 deaths per 100,000 population)
- Accidents (45.5 deaths per 100,000 population)

Age 55 to 64 Years

- Malignant neoplasms (321.2 deaths per 100,000 population)
- Heart disease (207.3 deaths per 100,000 population)
- Bronchitis/emphysema (39.2 deaths per 100,000 population)

The CDC uses a multifaceted approach to mitigate the chronic disease burden: epidemiology and surveillance to monitor trends, environmental strategies to promote healthy behaviors, health system interventions to advance clinical and preventative services, and community resources to improve clinical management of chronic conditions (Bauer et al., 2014). In Box 23-2: *Healthy People 2020*, selected objectives and target goals for the 2020 leading health indicators are outlined to give the reader some perspective of the many tasks and opportunities that lie ahead for Americans. The *Healthy People* initiative was established in 1980 to provide structure for health-promotion and disease-prevention programs. Every 10 years, revised objectives and target goals are established for each leading indicator. For 30 years, Harston (2010) has tracked and disclosed gains made toward meeting the target goals as a result of the influence of the overall health-promotion program. In some cases, progression toward the target goals has been achieved, and in other cases regression has been noted.

Box 23-2

Healthy People 2020

Selected National Health-Promotion and Disease-Prevention Objectives for the Middle-Aged Adult

Overall Goals

- Improve access to high-quality health services.
- Improve health and well-being for all age groups.
- Reduce disparities across all racial and ethnic groups of Americans.

Objectives

- Increase the proportion of adults who have a specific source of ongoing care. The target is 89.4%, a 10% increase over 2010 expected by 2020. The baseline in 2008 was 81.3% of adults.
- Reduce the proportion of adults aged 18 years or older with physician-diagnosed arthritis who experience a limitation in activity due to arthritis or joint symptoms. The baseline in 2008 was 39.4%. The target is 35.5%.
- Reduce the proportion of adults with osteoporosis. The target is 5.3%, with a baseline of 5.9% of adults aged 50 years or older with osteoporosis in 2005 to 2008.
- Reduce activity limitation due to chronic back conditions. In 2008, 30.7 adults per 1000 population aged 18 years or older experienced activity limitation due to chronic back conditions. The target is 27.6 adults per 1,000 population.
- Reduce the annual number of new cases of diagnosed diabetes to 7.2 per 100,000 population aged 18 to 84 years. The baseline in 2009 (National Health Interview Survey) was 8.0 new cases per 100,000 population.
- Reduce the proportion of persons with diabetes with a hemoglobin A_{1c} value greater than 9%. The baseline was 17.9% in 2005 to 2008. The target is 16.1%.

- Reduce deaths from work-related injuries in all industries. The target is 3.6 deaths per 100,000 full-time equivalent workers. The baseline in 2007 was 4.0 work-related injury deaths per 100,000 full-time equivalent workers.

- Reduce the overall cancer death rate. The target for 2020 is 160.6 per 100,000 population. The baseline was 176.8 per 100,000 population cited in 2007.

- Reduce the proportion of adults with hypertension. The target for 2020 is 26.9%. The baseline was 29.9% in 2005 to 2008.

- Reduce coronary heart disease deaths. The target is 100.8 deaths per 100,000 population. The baseline in 2007 was 126.0 deaths per 100,000 population.

- Reduce the proportion of adults who are obese. The target is 30.6%. The baseline in 2005 to 2008 was 34.0% of persons aged 20 years or older.

- Increase the proportion of adults who engage in aerobic physical activity of moderate intensity on a regular, preferably daily, basis for at least 30 minutes per day to 47.9%. The baseline was 43.5% in 2008.

- Increase recent smoking cessation success for adult smokers. The target is 8.0%, with a baseline of 6.0% of adult smokers aged 18 years or older who last smoked 6 months previously.

Most of the leading indicators identified in *Healthy People 2020* are preventable, or at least modifiable. Knowledge of the direction of the program offers professional nurses an incentive to modify their practice and health-promotion education efforts to best help Americans achieve the target goals specified in the *Healthy People* initiative. Health education, often conducted by professional nurses, has been effective with adults who want to or must change their

lifestyle behaviors. Nursing professionals have contributed extensively in helping the nation to meet the target goals for heart disease, stroke, and many types of cancer.

Whereas the data analysis showed some progress toward reaching many of the *Healthy People 2010* target goals, there were a number of areas of backsliding. Most notably, greater proportions of Americans are obese and have symptoms of **high blood pressure** compared with the findings reported for *Healthy People 2000*. Hypertension and obesity are conditions that significantly affect the middle-aged adult. They often lead to heart disease, stroke, and the development of diabetes. Harston (2010) suggests that the 2010 goals were perhaps too ambitious; however, findings of other research positively confirm that more Americans were obese in 2010 than earlier in the decade. The most recent national data from 2011 to 2014 on obesity prevalence indicate obesity was higher among middle-aged adults (40.2%) than among younger (32.3%) or older (37.0%) adults (Ogden et al., 2015).

Areas of improvement in reaching the target goals for *Healthy People 2010* were encouraging. For instance, decreases were noted in the number of cancer deaths and in the number of injuries at work (CDC, 2012). Furthermore, laws that discourage or forbid smoking continue to have a significant impact across populations.

In sum, there was evidence of progress in meeting approximately 670 of 955 leading health indicator target goals. Projecting ahead for 2020, efforts must be directed toward the following: increasing awareness of the *Healthy People 2020* initiative as a tool to improve the overall health of Americans; expanding knowledge of the initiative in schools, tribal communities, and local health agencies through the use of public service announcements carried on radio, television, and Internet-based programs; and linking the objectives and goals to preventive health provisions associated with work sites (occupational health programs) and health insurance policies. The good news is the *Healthy People 2020* target goals are more achievable (less ambitious than projected for 2010), and the objectives focus on individuals more than on "big" programs. There are goals that involve health counseling and behavior-modification strategies provided by nurses,

advanced practice nurses, and mental health nursing specialists in addition to physicians. In the larger picture, Americans will benefit when nurses, in all roles, incorporate the *Healthy People 2020* objectives into their practice.

Sex and Marital Status

In the midlife years, the death rate for men is higher. Men are more likely than women to die of heart disease for all age groups (35–44, 45–54, and 55–65 years) and all racial and ethnic groups (*Healthy People 2020,* 2012). Although cardiovascular disease death rates are declining for both sexes, heart disease remains one of the primary causes of death. The risk factors for heart disease include obesity, lack of physical activity, smoking, high total cholesterol level, hypertension, and genetics. **Obesity** is common, serious, and costly. More than one-third of US adults (36.5%) were reported to be obese in 2011 to 2014. Among American adults, the prevalence of obesity among middle-aged women was higher (38.3%) than in men (34.3%) (Ogden, et al., 2015). (See Chapter 11 for a discussion of overweight, obesity, and *Healthy People 2020* target goals.)

Nearly 60% of adults in the United States are married. The marriage rate for white adults (61%) is higher than that for Hispanic adults (58%) or black adults (38%). Married adults report better health than divorced, widowed, or never-married adults. Findings from the most recent census (2010) show that the number of interracial and interethnic married couples increased by 28% in the preceding decade. Among unmarried, opposite-sex partners, 18% described their union as interracial or interethnic whereas 21% of same-sex couples reported they have an interracial union (US Census Bureau, 2012).

Race, Sex, and Ethnicity

Black Americans are the second largest racial group in the United States. They constitute 12.6% of the US population (US Census Bureau, 2015). In actual numbers, there are slightly fewer than 40 million black Americans.

Cancer is the leading cause of death for black men and black women (combined incidence rates) in middle age. Findings in recent years show an encouraging decrease in both the incidence and the mortality rate for cancer among black adults since 1993. Black adults are less likely to survive 5 years after diagnosis than white adults. Researchers believe that this disparity is largely related to factors associated with a significantly lower income level than other racial or ethnic groups. Although black Americans constitute 13% of the US population, they represent 25.8% of the nation's poor (Macartney, et al., 2013; US Census Bureau, 2015). Black households have the lowest median income ($34,598), compared with non-Hispanic whites ($58,270), Hispanics ($40,963), and Asians ($67,065) (DeNavas-Walt & Proctor, 2014).

According to the US Census Bureau (2015), Hispanics are the largest ethnic group in the United States, constituting approximately 17.3% of the total population. Data from the National Vital Statistics Reports (2016) indicate accidents (unintentional injuries) are the leading cause of death for 35- to 44-year-old Hispanics; malignant neoplasms rank first among the causes of combined deaths of males and female Latinos aged between 45 and 55 years. Mortality statistics show the set of leading causes of death for white, middle-aged Americans is the same as that for Hispanics.

Individuals who describe their ancestry as Asian/Pacific Islander constitute approximately 5% of Americans. Across all age groups representing “the middle-aged adult,” malignant neoplasms and heart disease ranked as the leading causes of death within the Asian/Pacific Islander population. The types of cancer found most often among Asians are liver (including intrahepatic bile duct) and stomach cancer.

American Indians and Alaska Natives represent approximately 1% of the American population. Mortality statistics for both sexes aged 35 to 44 years show accidents to be the leading cause of death; heart disease kills more 45- to 54-year-olds, and in the oldest group (55- to 65-year-olds), malignant neoplasms, notably cancer of the kidney and renal pelvis, cause the greatest number of deaths.

Access to Health Care

Individuals who are poor, defined as having an annual income less than $20,000 for a family of four, generally have less access to medical care compared with people with a greater income. Driscoll and Bernstein (2012) reported that people who were unemployed self-reported a "poor psychological and physical health status" more often than individuals who were employed. The gravity of the situation increases because of the lost benefits, including health insurance, when individuals become unemployed. Furthermore, government reports indicate that the cost of health insurance premiums has increased and employee medical claims are at an all-time high and continue to rise. Two national initiatives have helped increase access to health care: slow trending increased rates of employment and the Patient Protection and Affordable Care Act, commonly known as the Affordable Care Act (ACA). The employment rate for US adults aged 25 to 65 years was higher in 2014 (72.3%) than it was in 2010 (71.5%) but remained lower than in 2008 (75.5%) or 2000 (77.7%) (National Center for Education Statistics, 2015). Middle-aged adults who remain employed often receive employer-provided health care benefits. Although health care policies vary, guaranteed health insurance significantly reduces the cost of preventative and emergent health care. Furthermore, business leaders across America are offering workplace health programs to help employees adopt healthier lifestyles, lower their risk of developing costly chronic diseases, and curb rising health care costs (CDC, 2016h). On March 23, 2010, the ACA was enacted to increase the quality and affordability of health insurance, lower the uninsured rate by expanding public and private insurance coverage, and reduce the costs of health care. Since the enactment of the ACA, the number of uninsured individuals has continued to decline. The proportion of adults aged 18 to 65 years who were uninsured at the time of interview decreased from 16.3% in 2014 to 13% in the first 3 months of 2015. During this same period, there was a corresponding increase in private health care insurance coverage from 67.3% to 70.4% (Cohen & Martinez, 2015).

Health care insurance coverage, access, and utilization disparities

exist. Compared with 2013, the proportion of adults aged 18 to 65 years who were uninsured decreased in 2014: Hispanics 41.1% to 34.1%, non-Hispanic whites 14.5% to 11.5%, non-Hispanic blacks 24.7% to 17.6%, and non-Hispanic Asians 16.1% to 12.2% (Martinez et al., 2015). Because of costs, those without health insurance often forgo needed health care, which can lead to continued compromised health status and potentially to greater medical expenditures in the long term. People 18 to 64 years of age with chronic conditions and without consistent health insurance coverage are much more likely to forgo needed medical care than people with the same conditions and continuous coverage (CDC, 2010b).

The second leading cause of death of non-Hispanic black Americans is heart disease. Of concern is that black Americans are less likely to receive a diagnosis of heart disease, but they are 30% more likely to die of heart disease compared to the population in general. Hypertension and overweight/obesity are risk factors for heart disease and stroke. Black adults are 50% more likely to have hypertension. A higher proportion of black women (77%) than white women (57%) are overweight. Black adults are 50% more likely than white adults to suffer a stroke.

Non-Hispanic black Americans share a disproportionate burden of HIV/AIDS. Black men are eight times more likely than non-Hispanic white men to have HIV/AIDS. Black women are 20 times more likely than non-Hispanic white women and almost five times more likely than Hispanic/Latino women to have HIV/AIDS. In 2010, blacks accounted for 45% of all new HIV infections among US adults despite representing only 12% of the US population (CDC, 2017b).

Latino/Hispanic Americans are the largest ethnic minority group in the United States, constituting 16.3% of the population. Hispanic Americans have the highest uninsured rate of any racial or ethnic group in the United States. From 2004 to 2014, the percentage of uninsured individuals younger than 65 years for whom cost was a reason for not having health insurance coverage decreased from 60.9% to 51.4% among uninsured Hispanics, from 49.5% to 38.0% among non-Hispanic whites, and from 47.4% to 34.0% among non-Hispanic

blacks (CDC, 2015c). Cancer is the second leading cause of death for young (35–44 years) middle-aged Hispanics, surpassing unintentional accidents. As the Hispanic population ages (into the 45– 65-year age range), neoplasms become the leading cause of death. Breast cancer is the most common type of cancer in Hispanic women. In Hispanic women, breast cancer is less likely to be diagnosed when the disease is localized, before spreading to nearby lymph nodes, tissues, and organs, and they are approximately 20% more likely to die than non-Hispanic white women even when breast cancer is diagnosed in them at a similar age and stage of disease.

Heart disease ranks second as a cause of death among Latino/Hispanics who are 45 to 64 years old. Hispanic adults are less likely to smoke than non-Hispanic white adults, but almost 80% of Mexican Americans are overweight; 42.3% of all Mexican American women are obese. Mexican Americans constitute approximately 60% of the Hispanic population in the United States. Obesity increases the risk of diabetes, hypertension, heart disease, and premature death (Obesity Society, 2017). Obesity is also associated with increased risk of cancers of the esophagus, pancreas, colon and rectum, breast (after menopause), endometrium (lining of the uterus), kidney, thyroid, and gallbladder (National Institutes of Health [NIH], National Cancer Institute, 2015b).

Genetics

The middle-aged adult is at greater risk than the young adult of diseases known to be associated with genetics (i.e., familial characteristics). These conditions include diabetes, hypertension, Huntington chorea, arteriosclerosis, gout, obesity, heart disease, and alcoholism. There are some malignancies that are related to genetics; for example, women with a personal or family history of breast cancer are at a higher risk of developing this type of malignancy. In addition, individuals with a family history of colorectal cancer, rectal or colon polyps, or ulcerative colitis have an increased risk of developing this type of cancer (Box 23-3: Genomics).

Box 23-3

Genomics

Genotype Targeted Therapies for Lung Cancer

Lung cancer remains the leading cause of cancer-related deaths worldwide and the second most common cancer among both men and women in the United States. In 2013 (the most recent year numbers are available), 212,584 people in the United States (111,907 men and 100,677 women) were diagnosed with lung cancer and 157,176 people (85,658 men and 70,518 women) died of lung cancer (CDC, 2016b). The number of new lung cancer cases in men is expected to stay the same between 2010 and 2020, but more than 10,000 additional new lung cancer cases are expected to be found in women each year by 2020 (CDC, 2016a). Several types of cancer treatment are available—surgery, radiation therapy, chemotherapy, immunotherapy, hormone therapy, and stem cell transplant—yet the 5-year survival rate has not increased in several decades. Molecular and genomic profiling of lung tumors has revolutionized the treatment of metastatic non–small cell lung cancer (NSCLC). The Adjuvant Lung Cancer Enrichment Marker Identification and Sequencing Trials (ALCHEMIST) involve genetic screening of resected NSCLC specimens (Cardarella & Johnson, 2013). Patients whose tumors test positive for either epidermal growth factor receptor gene *(EGFR)* or anaplastic lymphoma kinase gene (*ALK*) mutations will be referred to the ALCHEMIST for genotype-directed targeted therapies (Govindan et al., 2015; NIH, National Cancer Institute, 2016). Adjuvant targeted therapy, based on tumor mutation genotyping, will likely improve outcomes for all NSCLC patients.

non-small cell lung cancer. *Clinical Cancer Research*, 24, 5439–5444; National Institute of Health, National Cancer Institute. (2016). *The ALCHEMIST lung cancer trial.* http://www.cancer.gov/types/lung/research/alchemist.

Gordon's Functional Health Patterns

Health Perception–Health Management Pattern

To promote health in the middle-aged adult, the nurse performs a health assessment that includes the person's values and beliefs, lifestyle patterns, general perceptions of health, and health practices (Pender et al., 2015).

Habits

The self-destructive habits of the middle-aged adult that have been practiced for years (cigarette smoking, excessive alcohol use, and overeating) begin to have visible consequences. As pressures increase, adults are tempted to turn to substances such as these as a crutch for coping with stress. Prevention is extremely important, primarily because withdrawal from any of these substances is a difficult process.

Risk Factors

The major risk factors for adults in the middle years are environmental and behavioral; they can be changed through teaching, counseling, and use of other nursing interventions. Helping adults to take care of themselves and to change, when indicated, can be accomplished on an individual or a group basis.

Some of the health-promotion needs of the middle-aged adult include acceptance of aging, the need to exercise, and weight control. Decreasing or stopping cigarette smoking and alcohol consumption can also be identified needs. Preventive health screening is vital. The adult needs input into and control of as many of these behaviors as possible.

The health risks of middle-aged adults overall are categorized as group risks (age, sex, race) and personal risks. Precritical secondary prevention includes periodic selective screening for the detection of disease before it becomes clinically apparent, such as a breast self-

examination. A suggested screening examination appears in Box 23-4.

Box 23-4

Screening Examination: Age 35 to 65 Years

Database

- Health history
- Health hazard appraisal
- Psychological inventories as needed

Physical Examination Emphasizing

- Weight and height
- Blood pressure, pulse rate
- Breasts
- Pelvis
- Prostate
- Testicles
- Eyes
- Mouth
- Skin

Laboratory Procedures

- Papanicolaou smear and human papilloma virus test: every 5 years

- Hemoccult test: three stools for the Hemoccult test with physical examination after age 50 years
- Colonoscopy or sigmoidoscopy every 5 to 10 years after age 50 years as indicated
- Mammography: initial screening at age 40 years, annually at age 45 to 54 years, then every 2 years at age 55 years or older
- Urinalysis: examined at the time of physical examination
- Lipid profile: all men aged 35 years or older; women aged 20 years or older who have heart disease or risk factors for heart disease
- Chest radiograph with physical examination if heavy smoker
- Tetanus and diphtheria booster every 10 years
- Influenza vaccine: follow current recommendations
- Counseling and testing for HIV as indicated
- Rubella serological test (women of childbearing age)

Self-Care Education and Counseling

- With physical examination; individualized according to individual's risk factors
- Injury prevention: seat belts, helmets, firearms, smoke detectors
- Stress reduction
- Exercise
- Diet: cholesterol, fat, sodium, fiber, multivitamins with folic acid (women of childbearing age)

- Calcium
- Breast self-examination
- Testicular self-examination
- Dental care
- Mouth care
- Sexually transmitted diseases
- Contraception
- Skin protection from ultraviolet light
- Alcohol and other substance abuse
- Smoking cessation
- Possible hormone prophylaxis (perimenopausal and postmenopausal women)

(2016). *Preventive screening guidelines for healthy adults.* https://www.bluecrossma.com/wps/portal/members/healthier-living/manage-my-health/screening-guidelines-adults/.

Chronic conditions are defined as those that last for more than 3 months. The leading chronic diseases found in the middle-aged adult include heart disease, stroke, cancer, diabetes, obesity, arthritis, hepatitis, weak or failing kidney function, and chronic obstructive pulmonary disease, all of which are among the most common, costly, and preventable of all health problems (Lubkin and Larsen, 2013; Ward et al., 2014). As of 2012, nearly half of all American adults (49.8%, 117 million) had at least one chronic condition, of which more than half (approximately 60 million) had multiple chronic conditions:

24.3% had one chronic condition, 13.8% had two chronic conditions, and 11.7% had three or more chronic conditions (Ward et al., 2014). The cost of treating people with chronic diseases accounts for 86% of US health care costs. Two of these chronic diseases—heart disease and cancer—together accounted for nearly 48% of all deaths (CDC, 2016b).

Nutritional-Metabolic Pattern

Dietary factors are correlated with 5 of the 10 leading causes of death in the United States: coronary heart disease, some cancers, stroke, non–insulin-dependent diabetes mellitus, and atherosclerosis (CDC, 2010a).

Physical activities and nutritional patterns are frequently correlated. The middle-aged adult typically leads a more sedentary lifestyle than does the young adult primarily because of increased responsibilities at work and home and the many convenience devices that are found in homes and workplaces. Research findings published on the CDC website show that the incidence of obesity is increasing among men and boys compared with women and girls. Linked with less activity is the lack of attention to modification of food intake and calorie consumption, resulting in obesity, one of the major health problems of the middle years.

Obesity

More than one-third (36.5%) of US adults have obesity (CDC, 2016a). Obesity-related conditions (heart disease, stroke, type 2 diabetes, and certain types of cancer) contribute to the leading causes of preventable death. **Body mass index (BMI)** is used as a screening tool for overweight or obesity. BMI is a person's weight in kilograms divided by the square of height in meters (CDC, 2016b). **Overweight** is defined as having a BMI between 25 < 30. A BMI of 30.0 or greater falls within the obese range. Obesity is frequently subdivided into categories: Class 1 (BMI of 30 to <35), Class 2 (BMI of 35 to <40), and Class 3 (BMI of ≥40) (CDC 2016d). Obesity is more frequent among middle-aged adults 40 to 59 years old (40.2%) and adults age 60 and

older (37%) than among younger adults age 20 to 39 (32.3%) (CDC, 2016b). Of note, the target goal of *Healthy People 2010* of 15% was not attained. The progress report on the *Healthy People 2010* goals indicates that there was an increase in the incidence of obesity to 34% of the adult population compared with 23% in 2008 (CDC, 2012).

Overweight and obesity are major risks factors for preventable, noncommunicable conditions that contribute to increased health costs, morbidity, and death. An increased BMI substantially raises the risk of coronary heart disease, high blood pressure, high cholesterol, stroke, type 2 (non–insulin-dependent) diabetes, gallbladder disease, osteoarthritis, sleep apnea, obesity hypoventilation syndrome, and endometrial, breast, prostate, and colon cancers (CDC, 2012, 2015a; World Health Organization, 2016). Individuals who are obese often suffer from social stigmatization, discrimination, and lowered self-esteem (Hunger & Major, 2015). The US Preventive Services Task Force (2014) recommends all adults be screened for obesity. For patients with a BMI of 30 kg/m^2, clinicians refer them to a more intensive, multicomponent behavioral interventions.

Women with less education and low incomes and black and Hispanic women are at an increased risk of being overweight. In addition to sex, race, and socioeconomic status, genetics may be a contributing factor. The most significant variables, however, are health behaviors, particularly food intake and exercise and activity patterns. Although an abundance of health information is available, these challenges persist.

As much as 40% of a typical American family's food budget is spent on food in restaurants or for take-out foods, both of which are usually higher in fat (including saturated and trans fats) and salt content than foods prepared at home (Agency for Healthcare Research and Quality, 2012). Losing weight and maintaining weight loss may require an individual to change eating and activity behaviors, but the social, food preparation, and consumption behaviors of the family must change as well.

Prevention of obesity is the goal of weight management during the middle years. When the adult is obese, a clear-cut history of the onset

is imperative. A lifelong history of obesity is significantly more arduous to alter than that of adult-onset obesity. A decrease in calories should be accompanied by at least 30 minutes of exercise five times a week. When calories are reduced and exercise is increased, weight loss is achieved and maintained.

The weight-management resources available to the adult are plentiful. Weight-management programs using behavior modification can be found in various settings, such as universities and work sites, Weight Watchers, Overeaters Anonymous, and Take Off Pounds Sensibly. If the nurse identifies a need for weight management and no program is available, a self-help group can be started. A suggested list of topics generated by the group is assembled. A discussion of basic nutrition with appropriate handouts is a good place to start. Having adults record their individual goals and keep a 1-week diet log is nonthreatening and helpful for future planning; it also gives the participants some responsibility in the program. Intake food journals assist the individuals in maintaining weight loss outcomes.

High Saturated Fat Diet

Lipid levels and ratios have a significant influence on cardiovascular and cerebrovascular morbidity and mortality rates. The National Heart, Lung, and Blood Institute considers a total blood cholesterol level less than 200 mg/dL as desirable. The mean total blood cholesterol levels for adults in the United States declined by 3.9% from 1988–94 to 2005–08, from 206 to 198 mg/dL, exceeding the 2010 target of 199 mg/dL. During the same time frame, the proportion of adults with high blood cholesterol levels fell by 28.6%, from 21% to 15%, also exceeding the 2010 target of 17% (CDC, 2012).

Much of this success is attributed to the use of statin drugs that lower the level of low-density lipoproteins in the blood. Some studies demonstrate the beneficial effects of estrogen administration on heart health (Mikkola, et al. 2015). The reference Coronary Primary Prevention Trial demonstrates that men at high risk of coronary heart disease are able to reduce the risk by approximately 2% for every 1% lower blood cholesterol level. Before using medication to reduce

cholesterol level, individuals with high cholesterol levels are advised to reduce their intakes of saturated fat, total fat, and dietary cholesterol; normalize their weight; and increase their level of physical activity. If lifestyle changes are not successful, medication is often advised.

Calcium and Vitamin D

Adequate **calcium** intake is essential for developing and maintaining bone mass. Additionally, calcium is needed for other physiological processes, including muscle contraction and blood pressure regulation. Men and women need a minimal daily intake of 1000 mg of calcium. Pregnant and nursing women need 1200 mg, and postmenopausal women need either 1000 mg (when taking estrogen) or 1500 mg (when not taking estrogen). When daily intake of calcium is less than adequate, the serum calcium level will be maintained by leaching calcium from bone, resulting in osteoporosis. Weight-bearing exercise contributes to bone mass by increasing mechanical stress on the bones, whereas **vitamin D** promotes calcium absorption and regulates serum calcium and phosphate concentrations to maintain bone health (Heaney, 2013). Together with calcium, vitamin D helps to protect older adults from osteoporosis.

Vitamin D also plays an important role in overall health and the prevention of chronic diseases. Emerging studies suggest an association between inadequate levels of vitamin D and an increased risk of chronic diseases, such as in osteoporosis, diabetes, heart disease, hypertension, cancers, obesity, depression, cognitive decline, fractures and falls, and autoimmunity (LaFevre, 2015; Nair & Maseeh, 2012). Worldwide, across all ethnic, sex, and age groups, an estimated 1 billion people have inadequate levels of vitamin D (Holick, 2012; Lips, 2010). Possible causes of vitamin D deficiency include an insufficient consumption of vitamin D–fortified foods, lack of dietary supplements, and limited exposure to sunlight. It is very difficult to achieve sufficient vitamin D intake through dietary sources alone as few foods naturally contain vitamin D. The food sources that provide vitamin D include fatty fish, dairy products, liver, and fortified cereals

and beverages. The best way to ensure adequate vitamin D serum levels is through supplementation (NIH, Office of Dietary Supplements, 2016).

Vitamin D is unique because it can be synthesized endogenously when the skin is exposed to ultraviolet B radiation. Many factors can interfere with ultraviolet B exposure and the body's ability to synthesize vitamin D from sunlight: seasons, time of day, length of day, location, cloud cover, smog, skin melanin content, and use of sunscreen (Nair & Maseeh, 2012). Aging may also impede cutaneous synthesis of vitamin D. As people age the skin cannot synthesize vitamin D as efficiently as when they are younger. Older adults are also more likely to spend more time indoors (homebound or occupations that limit sun exposure). Prolonged sun exposure to prevent vitamin D deficiency is not generally recommended because exposure to ultraviolet radiation increases the risk of skin cancer. The exact definition of a low vitamin D level is not well established. Daily vitamin D intake of 600 IU in adults aged 18 to 70 years and 800 IU in adults older than 70 years will meet the needs of most adults (Institute of Medicine, 2011) (Table 23-1).

TABLE 23-1

Dietary Reference Intake for Calcium and Vitamin D

DIETARY REFERENCE INTAKES FOR CALCIUM AND VITAMIN D						
List Stage Group	CALCIUM			VITAMIN D		
	Estimated Average Requirement (mg/day)	Recommended Dietary Allowance (mg/day)	Upper Level Intake (mg/day)	Estimated Average Requirement (IU/day)	Recommended Dietary Allowance (IU/day)	Upper Level Intake (IU/day)
Infants 0 to 6 months	*	*	1000	**	**	1000
Infants 6 to 12 months	*	*	1500	**	**	1500
1–3 years old	500	700	2500	400	600	2500
4–8 years old	800	1000	2500	400	600	3000
9–13 years old	1100	1300	3000	400	600	4000
14–18 years old	1100	1300	3000	400	600	4000
19–30 years old	800	1000	2500	400	600	4000
31–50 years old	800	1000	2500	400	600	4000
51–70 year old	800	1000	2000	400	600	4000

males						
51–70 year old females	1000	1200	2000	400	600	4000
>70 years old	1000	1200	2000	400	800	4000
14–18 years old, pregnant/lactating	1100	1300	3000	400	600	4000
19–50 years old, pregnant/lactating	800	1000	2500	400	600	4000

*For infants. Adequate intake is 200 mg/day for 0 to 6 months of age and 260 mg/day for 6 to 12 months of age.

**For infants. Adequate intake is 400 IU/day for 0 to 6 months of age and 400 IU/day for 6 to 12 months of age.

From The National Academies of Sciences, Engineering, and Medicine, Health and Medicine Division. (2010). Dietary reference intakes for calcium and vitamin D as recommended by the Institutes of medicine. http://www.nationalacademies.org/hmd/Reports/2010/Dietary-Reference-Intakes-for-Calcium-and-Vitamin-D.aspx.

Caffeine

Caffeine is a popular stimulant found in coffee, tea, and some soft drinks, such as colas. Caffeine prolongs the amount of time that physical work can be performed and appears to decrease boredom and increase attention span. On the negative side, coffee has recently been the subject of significant scrutiny from the media, with reports of a link between cancer of the pancreas and coffee consumption. There is controversy regarding whether daily moderate intake of caffeine has any detrimental effects.

Like alcohol and nicotine, caffeine is readily available and has become an accepted part of daily living. Because caffeine is a strong stimulant with effects that are typically taken for granted, its importance as an addictive substance must be emphasized. Ingestion of 0.5 g of caffeine (three to four cups of coffee) can increase the basal metabolic rate by an average of 10%, and possibly as much as 25% for some people.

Long-term stimulation of the central nervous system results in restlessness, sleep disturbances, cardiac stimulation, and withdrawal effects. Nurses' assessment should screen individuals for stimulating

and addictive substances that may be producing these symptoms.

High-Sodium Diet

High-sodium diets play a significant role in hypertension, especially when consumed over many years. The result may be an increase in the amount of total body fluids, which increases peripheral vascular resistance. Salt contains approximately 40% sodium and is a contributing factor for hypertension in the 10% to 20% of Americans who are at risk. On average, Americans consume 4 to 5 g of sodium per day. A major contributor to dietary sodium is the salt found in processed foods.

In the past 3 decades, many clinical studies have demonstrated the effectiveness of lowering blood pressure by lowering dietary sodium intake. Other studies have described the relationships between urinary and sodium excretion and the change of blood pressure with age (Pöss et al., 2015).

Alcohol Abuse

Substance abuse can be a devastating habit. Many adults abuse prescription and illicit drugs and, especially, alcohol. Alcohol is frequently treated as a nondrug, but alcohol addiction is second only to nicotine addiction. Alcohol is readily available, reasonably inexpensive, and considered a part of social exchange; its long-range physiological and psychological effects are well documented. It is estimated that 16.6 million adults in the United States struggle with alcohol use disorders. These affect men (9.8 million) nearly twice as often as women (5.8 million). In 2013, approximately 1.3 million adults received treatment for an alcohol use disorder at a specialized facility (7.8% of adults who needed treatment). This included 898,000 men (8.8% of men in need) and 417,000 women (7.5% of women who needed treatment) (USDHHS, NIH, NIAAA, 2015b).

The *Dietary Guidelines for Americans,* issued jointly by the US Department of Agriculture and the USDHHS (http://www.nutrition.gov), defines moderate drinking as no more

than one drink a day for women and no more than two drinks a day for men. Women are more vulnerable than men to the effects of alcohol because, pound for pound, women have less water in their bodies, and they tend to weigh less than men. This means that identical doses of alcohol per kilogram of body weight will result in significantly higher blood alcohol levels in women. A woman's brain and other organs are exposed to more alcohol and to the toxic by-products of alcohol as it is metabolized. A woman is more likely to drink excessively if her parents, siblings, or other blood relatives have problems with alcohol; if she was abused physically or sexually as a child; if her partner drinks heavily; if she is experiencing difficulties with intimate and close relationships; or if she has a history of depression. (USDHHS, NIH, NIAAA, 2015a). Research also suggests that a woman's heavy drinking patterns may be associated with posttraumatic stress disorder, eating disorders, and suicidality although causality in the associations remains unclear (Wilsnack et al., 2014).

Alcohol use disorders are associated with motor vehicle accidents, violence, homicides, suicides, drownings, heart disease, strokes, liver disease, pancreatitis, and fetal alcohol syndrome. Fetal alcohol syndrome is the most common known preventable cause of mental impairment. The brain damage that occurs with fetal alcohol syndrome can result in lifelong problems with learning, memory, attention, and problem-solving (USDHHS, NIH, NIAAA, 2015a).

Initially, alcohol appears to be a stimulant, but it is actually a central nervous system depressant and anesthetic. Long-term alcohol use produces tolerance, thereby necessitating a gradual increase in dose to achieve the same effect. Alcohol contributes to problems with safety because of decreased reaction time and depression of the central nervous system. Those experiencing alcohol use disorders may report symptoms such as heartburn and gas, stomach distention, poor eating habits, nausea and vomiting, gastric pain, right upper quadrant pain, and irritation of the mouth, throat, and esophagus. Two additional subtle findings are spider angiomata and palmar erythema.

Primary prevention for substance and alcohol abuse is complex,

especially because adults consume these agents for many reasons, including peer pressure, loneliness, alienation, frustration, anxiety, and low self-esteem. Heavy drinkers may also be following the example established by influential people in their lives. Merely telling people about the potential physical, emotional, and legal hazards appears to have little effect as a preventive measure. Promotion of more realistic portrayals of substance abuse through the media is difficult to implement. Although techniques such as assertiveness training and teaching adults to resist persuasion are helpful, more useful approaches might include helping them learn to manage anxiety and increase their self-esteem. Less anxious and more confident people have greater skills in resisting peer influences to participate in substance abuse; they also are more likely to have fewer episodes of isolation and loneliness.

Early detection and intervention can decrease ongoing and future physical and psychosocial problems resulting from alcohol abuse. Nurses use a variety of screening strategies to identify individuals' perceptions and consequences of drinking. The CAGE questionnaire is one of the most popular screening tools used in primary care. The Michigan Alcohol Screening Test (http://counselingresource.com/quizzes/alcohol/-mast/index.html) and the Alcohol Use Disorders Identification Test (https://www.drugabuse.gov/sites/default/files/files/AUDIT.pdf) are examples of other screening instruments.

Abnormal laboratory test results, including elevations in aspartate aminotransferase level, erythrocyte mean corpuscular volume, and serum glutamyltransferase level, are not adequately sensitive and specific enough to detect alcohol use disorders as these may be a result of other causes, including trauma, disease, and medications.

A variety of treatments are known to be effective, but no single "best" intervention has been identified. Effective treatments may be to address other problems with use of interventions such as pharmacological agents, stress management, acupuncture, individual and family therapy, and supportive environments.

Oral Health

Gingivitis.

Gingivitis is found commonly among adults who fail to brush their teeth and use dental floss regularly. Redness and swelling develop around the teeth. Bleeding of the gums, while the teeth are being brushed, is an early sign of gingivitis. The gums may or may not be tender. When inflammation is not adequately treated and controlled, **periodontitis,** involving bone destruction, can develop in addition to tooth loss.

Dental hygiene and decay.

Dental health is essential to overall health. Brushing the teeth and flossing after eating, receiving routine dental checkups, and consuming fewer carbohydrates (especially simple sugars) are important interventions to prevent dental caries. Adults in the middle years have responsibility not only for their own regular dental care but also for the care of their children and parents. Fluoridation of water (versus bottled or tap water) and use of applied sealants are additional health choices that support prevention of dental caries and, possibly, tooth loss.

Dental health is one of the leading indicators identified in *Healthy People 2020*. There is increasing evidence to show that periodontal, or gum disease, is closely linked to diabetes, heart disease, and stroke. For the middle-aged woman, poor oral health can cause premature births and low-birth-weight infants (Bensley et al., 2011).

There are many conditions that begin with changes in the oropharyngeal mucosa, such as cancer of the mouth and esophageal cancer. Consequently, annual dental checkups are important because dental professionals (dentists or dental hygienists) may be the first to detect a symptom or irregularity that points to a potentially dangerous condition.

Findings described on the *Healthy People 2020* oral health webpage indicate that approximately 41.2% of Americans representing all racial and ethnic groups receive annual health care by a dentist. The target

goals for oral health services use (OH-7 outlined in the objectives for *Healthy People 2020*) indicate an expectation of a 10% increase in the proportion of adults and children aged 2 or older who receive dental care annually. The target goal is 49.0% of the population seeking dental care on an annual basis compared with the baseline of 41.2% reported in 2012.

People who are in vulnerable populations (individuals whose annual income is below the poverty line, others who are chronically ill or disabled, or still others whose medical or psychiatric treatment plans are very complicated) may not receive adequate or proper oral health care. The Surgeon General commented that, whereas there is evidence of progress being made to increase access to oral health services for a greater proportion of the population, those who are vulnerable because of their illness, such as people with HIV/AIDS, still find difficulty in obtaining proper and adequate oral health care (Benjamin, 2012). The Oral Health Care Initiative will help address the multilayered complexities that people with HIV/AIDS face. The factors that frequently deter oral health care in this population include lack of dental insurance, lack of transportation, limitations of disability, increasing costs of treatment, inability to afford the cost of oral health care, and discrimination on the part of dental health care providers. In sum, "the lack of dental care for individuals with HIV and AIDS undermines their treatment and diminishes their quality of life which in turn, can affect the overall outcomes of their overall treatment regimen" (USDHHS, 2010).

National data also indicate that the cost of dental care is a major deterrent to sustained oral health. Findings from the Healthy People Final Review (CDC, 2012) indicate that 16% of dentate adults aged 18 to 64 years reported an unmet dental need because of cost in the previous 12 months. Among adults aged 18 to 64 years, the main reason to forgo a dental visit for an oral health problem in the previous 6 months was cost; 42% could not afford treatment or did not have insurance.

Tobacco use in any form (cigarettes, pipes, and smokeless [spit] tobacco) raises the risk of gum disease. Findings from Bloom et al.,

2012 indicate that dental health is often poor among smokers (currently smoking) compared with former smokers and with those who have never smoked. Smokers who were interviewed said that they had three or more dental problems. In addition, current smokers reported infrequent visits to their dentist (in some cases, more than 5 years) or never seeing a dentist. Research findings indicate the prevalence of gum disease is two times greater in individuals who smoke cigarettes compared with individuals who have never smoked (CDC, 2017f).

In summary, oral disease is preventable. Regularly scheduled dental care with a dentist and dental hygienist is highly recommended for good dental hygiene and early treatment of dental decay and periodontal diseases, such as gingivitis. In addition, dentists can provide screening for oropharyngeal cancer. Oral health is essential in the overall digestive and elimination processes.

Elimination Pattern

Aging brings a gradual decrease of tone in the large intestine. This change, accompanied by a sedentary lifestyle, lack of fiber in the diet, and inadequate fluid intake, can predispose the adult to constipation. Advertising on television and other forms of media present strong arguments that encourage individuals to rely on external controls rather than on exercise and dietary means to solve this problem. Consequently, many adults are dependent on taking fiber products, as well as laxatives, for regular bowel movements.

In the kidneys, degenerative changes in the nephron units gradually increase during the middle years. In most cases, adults do not have any appreciable alteration in kidney function unless the person has experienced repeated infections, trauma, or the long-term effects of diabetes mellitus or hypertension.

Alteration in bladder control (incontinence) can occur in both women and men because of weakening of the muscles of the pelvic floor or damage to pelvic nerves. Urinary incontinence is problematic in women who have experienced multiple births. In men, urinary incontinence frequently occurs as a complication of surgery for

prostate cancer. Incontinence can be socially embarrassing, but the condition can be relieved with Kegel exercises (Santacreu & Fernández-Ballesteros, 2011; Siegel, 2014).

Activity-Exercise Pattern

Regular physical activity increases life expectancy and the quality of life. Exercise helps to prevent coronary heart disease, hypertension, diabetes, osteoporosis, and depression. Research findings show there is a strong correlation between physical exercise and lower rates of osteoporosis (National Osteoporosis Foundation, 2014), back injury, stroke, and colon cancer. Weight loss programs that incorporate physical activities also make significant contributions to health promotion as evidenced by increased life expectancy and quality of life.

One of the objectives of *Healthy People 2020* is to continue to decrease deaths related to heart disease. Evidence suggests that a significant percentage of Americans in the middle-aged adult bracket do not engage in regular moderate physical activity for at least 30 minutes on five or more days a week. Only a fraction of adults perform the recommended level. The proportion of adults who did not participate in any form of leisure-time physical activity (objective 22-1) decreased by 9% between 1997 and 2008, from 40% to 36%, moving toward the 2010 target of 20% (CDC, 2012). Sedentary behavior increases with aging. This finding may be due to the onset of conditions that affect mobility and strength.

Continuous, rhythmic exercise maintained for a period sufficient to stress the cardiac system (increase heart rate and blood pressure) is desirable. Some suggested activities include brisk walking, jogging, swimming, bicycling, and skipping rope, as well as walking or biking to work. Activities that focus on skill and coordination should be attempted by the adult older than 40 years rather than activities necessitating speed and strength. Moderation is key for all groups of individuals. Caution is recommended for adults nearing age 65 years to prevent muscle strains and/or falls. Overexertion, as evidenced by dizziness, chest pressure or chest pain, and unresolved shortness of

breath, should be avoided. Additionally, in hot weather, strenuous exercise should be balanced with rest periods and increased intake of fluids to prevent heat stroke.

Nurses play significant roles in assessing, teaching, and evaluating individuals relative to activity-exercise programs. Advanced practice nurses are often instrumental in creating and guiding weight loss programs; nurses working in the community may see local citizens at health fairs or health-promotion events; and other nurses or therapists visit individuals at home for care following hospitalization for surgery or acute illness as home health professionals. Activity programs are initiated to restore health (following heart attack) or to improve cardiac function (such as cardiac and pulmonary rehabilitation), and in some cases to control blood glucose levels. A thorough assessment, including a cardiac stress test, is necessary when an individual has not exercised regularly in the past. Parameters for heart rate, blood pressure, and length and frequency of exercise sessions are set in advance by a cardiologist. Nurses support and guide individuals by helping them determine program goals, by monitoring their progress, and by teaching individuals how to modify lifestyle behaviors to obtain particular objectives.

To achieve maximal effectiveness, physical exercise should involve as many muscles as possible and be performed on a regular basis. Adults should spend 30 minutes or more in brisk physical activity every day for a total of 3 to 4 hours per week. The optimal performance level differs for each individual and should be based on parameters set by the individual's physician in advance of the individual starting a fitness program. The following formula to calculate the target heart rate is shown on the American Heart Association (2012) website. Begin by subtracting one's age from 220 and then multiply this number by 0.75 to determine a heart rate that is within safe limits. For example, for an individual who is 50 years old, (220 − 50) = 170; 170 × 0.75 = 127.5 (or 128 beats per minute) for the optimal heart rate. Comparatively, the cardiac muscle capacity of a person younger than 50 years would be greater than 128 beats per minute; and as the functional aerobic capacity is increased, the target

heart rate required to tone the cardiac muscle will increase.

To summarize, routine exercise is essential to the health of the heart and overall muscle strength. The type of activity and style is an individual choice. Program goals are achieved more readily when exercise is incorporated into leisure activities or is a part of a group activity.

Sleep-Rest Pattern

Middle-aged Americans may not get as much sleep as young adults because of increased demands in their lives. Caring for immediate family, children, and sometimes parents, as well as employment responsibilities, consume most of a 24-hour period.

Insomnia is a common finding in this age category. It may be the result of overstimulation resulting from drinking too many caffeinated beverages, strenuous exercise within 2 hours of bedtime, or failure to have a regular sleep-wake schedule in a 24-hour period (National Sleep Foundation, 2017). Frequently occurring insomnia can lead to distractibility, irritability, and fatigue during the daytime hours.

Sleep apnea is a common disorder during which normal breathing is disrupted by breathing pauses or shallow breaths. Breathing pauses may occur 30 times or more each hour and may last from a few seconds to minutes. Because of collapsed or blocked airways, a loud snorting or snoring sound is produced when normal breathing resumes. This pattern of pauses and shallow breathing is typical for the most common type of sleep apnea: obstructive sleep apnea. Although obstructive sleep apnea may be experienced by all, this type of sleep apnea commonly affects obese adults. Central sleep apnea is the less common type of sleep apnea. It occurs because of a disruption of central nerve signals to the diaphragm resulting in brief periods of not breathing while asleep.

Sleep apnea is a chronic condition and may increase the risk of myocardial infarction, stroke, arrhythmias, and heart failure. Treatments include lifestyle changes such as weight loss, continuous positive airway pressure therapy, the use of mouthpieces, or surgical

intervention (USDHHS, NIH, National Heart, Lung, and Blood Institute, 2012).

Rest is essential to allow restorative functions of the body to occur. The effects of insomnia can be counteracted by regularly scheduled, high-quality sleep, and occasional napping when fatigued. If insomnia becomes a chronic problem, cognitive-behavioral therapy has also been demonstrated to be an effective treatment option (Kaldo et al., 2015). The National Sleep Foundation (http://www.nationalsleepfoundation.org) offers detailed information about treating insomnia and other **sleep disorders** with medications if that modality is indicated.

Cognitive-Perceptual Pattern

Learning is a phenomenon that occurs across the life span. The need to increase knowledge or information and the need to acquire new skills are constants as adults develop through a variety of experiences. Employment demands or new roles in life, such as becoming a parent or suddenly needing to care for an elderly family member, thrust the middle-aged adult into numerous different learning situations. The ability to learn a range of skills or to acquire knowledge through observing, performing, or participating in play activities begins in childhood as described by Gardner (1983, 1993) and extends into the middle years and beyond. The capacity to perform intellectually (i.e., reason through critical thinking, use/increase vocabulary, and apply spatial perception skills) stays constant through the 35- to 65-year-old age range. However, some decreases in reaction time and cognitive flexibility become more apparent as age increases.

Intellectual Ability

The ability to acquire new knowledge or skills, or "learning intelligence," accumulates through formal education and life experiences and continues to increase throughout life. The evidence of this phenomenon is demonstrated by the many scholars and artists who become more productive in their middle years than when they

were young adults. Some individuals discover “new talents” later in life because they have more leisure time or motivation to explore new areas or interests.

The theories of Piaget (1970), Bloom (1984), and Havighurst and Orr (1956) are relevant to the middle-aged adult. These theorists conclude that the prime time to be in the learner role is when the developmental task for that role is to be accomplished. The adult in the middle years as the learner-performer is a case in point. For example, to balance the responsibilities of caring for children and parents and being employed outside the home, the adult may explore new career options or creative endeavors.

Havighurst and Orr (1956) defines developmental tasks as the basic tasks of living that must be achieved for the adult to live successfully. These tasks are dictated by the expectations of society, the physiological changes of the body throughout life, and the individual's own value system and goals. Although initially described in 1956, Havighurst and Orr's developmental tasks of middle age remain timely (Box 23-5).

Box 23-5

Developmental Tasks of Middle Age

- Helping children become responsible, happy adults
- Rediscovering or developing new satisfaction in the relationship with one's spouse (for the single adult, this can occur in a relationship with a sibling or significant other)
- Developing an affectionate, but independent, relationship with aging parents
- Reaching the peak in one's career
- Achieving mature social and civic responsibility

- Accepting and adapting to biological changes
- Maintaining or developing friendships
- Developing leisure-time activities

If career goals have been previously identified, then attaining them can be highly rewarding, both psychologically and financially. In addition to career activities, the mature adult has an increased social awareness and often assumes more civic responsibility.

Piaget's theory of cognitive development, formal operations are the highest or most complex level. This stage begins at approximately age 12 years and continues throughout life. Piaget describes the thoughts of adults as being both flexible and effective. The adult can deal efficiently with complex problems of reasoning, including hypothesis testing (Piaget, 1970).

Bloom (1984) developed a hierarchy of cognitive levels in the adult learner. Knowledge is the simplest or most basic cognitive level. Knowledge is the acquisition of information. The adult learner defines "high blood pressure" in lay terms.

Comprehension is the second level, as indicated by the learner grasping the meaning of the communicated message and relating the term(s) to other material. For example, the individual can state one way that obesity influences high blood pressure.

The third level is application of knowledge. At this level the learner demonstrates an understanding of ideas and concepts by extending them to describe or relate them to real-life situations. For example, the individual with hypertension becomes involved in an exercise program.

The fourth level is analysis. At this level, all aspects of learning are united in thought, and the individual is cognizant of the relationships and interactions of all the parts. For example, the individual considers his or her values and life goals when making decisions about taking action in regard to understanding health care needs.

The highest order of learning involves synthesis and evaluation. The person is able to combine various elements to form a plan and

then is able to judge the extent to which the actions and results satisfy the original objectives. For example, people may develop plans to improve their health status and increase their disease self-management responsibilities. The next step is to validate the results of ongoing health care programs in relation to their projected expectations. Genetic and personality factors, in combination with environmental conditions and lifestyle practices, account for the large difference in the ways in which individuals maintain mental abilities. Schaie and Willis (2005) have identified seven factors that maintain cognitive function in later life:

- Absence of chronic diseases
- Living with favorable socioeconomic factors, including maximal occupational complexity, a low degree of routine, and an intact family
- Involvement in complex social activities
- Flexible personality style
- Marriage to a spouse with high cognitive function
- Maintaining high levels of performance speed
- Personal satisfaction with accomplishments in midlife and early old age (see Box 23-5)

Perceptual Changes

Presbyopia (farsightedness) is common in middle-aged adults, even in individuals who have had no previous problems with their vision. This condition occurs because of the loss of elasticity in the lens of the eye so that the adult cannot focus on objects that are in close range, such as reading without using prescription lenses.

Presbyopia is corrected with prescription lenses, which may be needed only for reading or for close work. LASIK surgery, a surgical intervention to correct refraction, is currently widely used and is favored by individuals who do not want to use standard eyeglasses.

Other visual conditions that may not be as easily corrected include decreased peripheral vision and decreased visual sensitivity in the

dark. Both conditions are slow and insidious in their development and occur as the cornea becomes less transparent. Because all these conditions are not readily detected by the individual, middle-aged adults should undergo a routine professional eye examination every year.

Glaucoma occurs as a result of increased intraocular pressure, which can damage the optic nerve, resulting in vision loss and blindness (CDC, 2017a). Loss of peripheral vision, or tunnel vision, is a common condition associated with glaucoma. Damage to the optic nerve is irreversible, but visual loss can be prevented if damage is identified early and treatment is initiated. Information available at http://www.aao.org/eyecare-america shows that glaucoma is the leading cause of blindness among black Americans in the United States. A current estimate is three times the number of black Americans compared with white Americans have glaucoma; also in addition, the rate of blindness attributable to glaucoma is four times greater in black Americans relative to white Americans. The importance of regular eye examinations by an ophthalmologist cannot be underestimated.

A **cataract,** opacity of the lens, can develop and cloud the vision in the later years of middle age. Often cataracts develop in people who have diabetes. Another disorder, diabetic retinopathy, gradually causes rupture of vessels in the retina, which leak into the eye causing lack of color differentiation and central vision changes.

Macular degeneration is often referred to as age-related macular degeneration (AMD). This age-related disorder is a progressive deterioration of the maculae of the retina and choroid structures of the eye and results in damaged sharp and central vision. Approximately 1.8 million Americans aged 40 years or older are affected by AMD, and the number of people with AMD is estimated to reach 2.95 million by 2020 (CDC, 2015b). This condition is very serious because it represents the effects of several disorders. Once a diagnosis of macular degeneration has been made, retinal ophthalmologists should be involved in the care of the individual.

Another common perceptual change in middle age is **presbycusis**

(impaired auditory acuity). The first sounds to be lost are higher frequencies, such as a woman's voice. This is important in the work environment and situations that require social interaction. Because this process is subtle, middle age is a time for auditory evaluations as a part of routine examinations.

Beginning in the middle years, the sense of taste diminishes in a progressive and predictable manner. The taste buds located more anteriorly on the tongue are the first to be affected, causing an inability to detect sweet and salt. When the effectiveness of the posterior taste buds declines, detection of bitter and sour flavors is lost. Consequently, this change can alter a person's food preferences and present problems for people who insist on adding salt to compensate for the deficit. Nurses involved in the care of the middle-aged adult, perhaps in the community or in home health, can show the individual how the use of various herbs and spices can enhance flavor.

Self-Perception–Self-Concept Pattern

Levinson's Theory

In Levinson's research on men (Levinson, 1986a,b) and women (Levinson, 1996), a theory on "individual life structures" is posed. Levinson describes age-associated seasons or eras. The midlife transition, beginning at age 38 to 40 years, appears to include reappraising one's life, integrating the polarities, and modifying one's life structure toward being who one wants to be. Middle-aged adults struggle with meaning, value, and direction of their lives.

Erikson's Theory

In Erikson's eight stages of the life cycle (Erikson & Erikson, 1998), the last three stages are related to adulthood. Stage 7, **generativity versus stagnation** or self-absorption, is most frequently associated with the middle years.

Erikson identifies generativity as the primary task to achieve during adulthood. Generativity includes a sense of productivity and

creativity as evidenced by reaching previously established goals versus stagnation, the failure to achieve lifelong goals (Hornstein, 1986; Reifman et al., 1991; Thomas, 1995). Generativity also encompasses a desire to care for others versus self-absorption, the tendency to direct most of one's interest and attention to oneself thereby excluding others.

Middle age is a time of critical self-review. For some, this review may prompt sadness, disappointment, self-doubt, and regret if the desired and expected life goals have not been met. Both women and men question their value to society, the merit of their accomplishments, their success as sexual beings, and the probability of attaining yet unfilled life goals. Women generally make this life assessment between 35 and 50 years or age, whereas men do not usually begin until approximately age 40 years. Women typically begin earlier to look for changes they may want to make in their lives (Apter, 1995), whereas men remain content with the status quo. Because the male life assessment tends to begin later, there is potential for couples of approximately the same age to experience conflict within the relationship. This type of self-review and lack of effective communication of personal needs with a spouse or life partner is a threat to marital stability (Erikson & Erikson, 1998; Vaillant & Vaillant, 1990).

Physiological Changes

The effect of physiological changes on mental health is nearly as critical during the middle years as it is during adolescence. Some of the most obvious changes that influence self-esteem are graying hair, an increase in the number of wrinkles, decreased visual and auditory acuity, and changes in body shape. The extent to which these changes are tolerated depends largely on the person's level of self-satisfaction and acceptance. Some people try to “hold on” to youth by dressing as more youthful counterparts dress, whereas others adapt their attire to their age and position in life.

Before 2002, hormone therapy (estrogen alone or estrogen and progesterone) was given to millions of postmenopausal women.

Estrogen is still the only therapy approved by the Food and Drug Administration for the treatment of hot flashes associated with menopause. Millions of women took hormone therapy not only to relieve hot flashes but also in the hope that it might prevent heart disease, the number one cause of death in postmenopausal women. All of that changed in 2002, however, when data from the Women's Health Initiative (WHI) showed that postmenopausal women who took estrogen and progesterone actually had higher rates of heart attacks and other health problems, including stroke, blood clots, and breast cancer.

Follow-up analysis of the WHI data showed that the effects of hormone therapy depend on a woman's age and the length of time since menopause. In younger postmenopausal women, between 50 and 59 years of age, hormone use did not increase the risk of cardiac events, as it did in older women. There is new evidence that hormone therapy may actually be beneficial for younger postmenopausal women, but for now, hormone therapy is not recommended for the prevention of heart disease (Whayne & Mukherjee, 2015).

Health benefits of hormone therapy include decreased risk of osteoporosis and decreased rates of colorectal cancer (American Cancer Society, 2015; Whayne & Mukherjee, 2015). Research is ongoing regarding the risks and benefits of hormone therapy. Currently, the only approved indication for postmenopausal hormone therapy is for the relief of moderate to severe vasomotor symptoms (hot flashes). Only short-term use is advised (1–3 years) (Lowdermilk & Perry, 2012).

Increasing numbers of women are now looking for non-hormonal ways to treat hot flashes and other symptoms associated with menopause. The law passed in 1994 to regulate dietary supplements provides some oversight for natural health products but does not require manufacturers to prove that dietary supplements are either safe or effective (AACE Menopause Guidelines Revision Task Force, 2011).

Because there are few scientific data, many midlife women find it difficult to make decisions about using alternative products. Black

cohosh, soy, and vitamin E are just a few of the products marketed to women. Even if these products are effective, women must be cautious about drug interactions that may occur. The use of prescription medication increases with age. The benefits of using alternative therapy may outweigh the risks, but more research is needed on the safety profile of natural remedies (AACE Menopause Guidelines Revision Task Force, 2011).

It is difficult to separate menopause from the physical and psychological changes that women experience as they age. The stressors common to women in their 40s and 50s include raising a family, helping parents as they age, coping with divorce or death of a spouse, retirement, and financial insecurity. Menopause happens in the midst of this. All the events in a woman's life influence her experience of menopause and the **perimenopause,** a period that precedes menopause and lasts approximately 4 years. Symptoms such as mood swings, nervousness, agitation, fatigue, and depression are often ascribed to the decline in estrogen levels that occurs during this time. The physiological changes are important, but a woman's experience in menopause is profoundly affected by all the events in her life (Lowdermilk & Perry, 2012).

Men also experience physical and psychological reactions to middle age. The hormonal changes in men are gradual, typically beginning between 40 and 55 years of age. The symptoms are similar to those experienced by women with the emotional effects related to other life events, past coping patterns, and general feelings of self-esteem.

Roles-Relationships Pattern

Middle age is frequently a time of reassessment, turmoil, and change. This time has been called **"midlife crisis."** The turning point occurs for several reasons. Over time, middle-aged adults become aware of subtle and compromising changes in physical, cognitive, and emotional agility. Furthermore, the inevitability of one's own death is recognized, perhaps for the first time. Middle-aged adults must accept that lifestyle choices have been made, unintended consequences may have lasting repercussions, and the opportunity to amend prior

decisions may no longer be possible. Alternatively, middle-aged adults may be quite satisfied with prior life choices and the resultant personal satisfaction and contentment (Box 23-6: Research for Evidence-based Practice).

Box 23-6

Research for Evidence-Based Practice

"Regrets are the natural property of grey hairs"—Charles Dickens

Disappointment and regret are common emotions experienced across all ages. Life-span theorists suggest that regret-producing consequences are associated with low levels of life satisfaction, low levels of subjective well-being, and high levels of biological age-related changes among midlife and older adults more often than among younger adults (Wrosch et al., 2005). Time lived was understood to intensify the degree of angst associated with perceived regrettable situations because middle-aged and older adults have less time to take corrective action or make amends.

The latest research suggests that middle-aged and older adults are less likely to engage in remorseful rumination than are younger adults (Brassen et al., 2012; Charles, 2010; Mather, 2012). Despite normative age-related physical decline, middle-aged and older adults typically report greater life satisfaction and remarkably higher levels of emotional well-being than young adults, including a decline in their experience of negative emotions (Chowdhury et al., 2014). Even in the presence of physical comorbidities, decreased cognitive agility, a diminishing social circle, and perhaps the death of a spouse, family member, or close friends, middle-aged and older adults have harnessed strategies that preserve emotional well-being, even as they continue to age (Mather, 2012). According to Mather (2012), age-related emotional processing has a biological basis that helps explains why patterns of coping with regret differ between young adults and

those in the middle years and beyond.

Family

Duvall and Miller (1985) delineate eight stages of the family life cycle, with stages 5, 6, and 7 in the middle years (see Chapter 7):

- Stage 5: Families with children, with the oldest child aged 13 to 20 years; lasts approximately 7 years
- Stage 6: Families launching young adults, from the first leaving until the last; lasts approximately 8 years
- Stage 7: Families from empty nest to retirement; lasts approximately 15 years

The developmental tasks identified for the families in stages 6 and 7 are similar to those described by Havighurst and Orr (1956); they focus on changes from a nuclear family to a marital couple with other responsibilities. For example, in stage 6, the parents who are helping their children become independent may also be caring for their aging parents. Additionally, middle-aged adults fulfill multiple complex responsibilities within a variety of career, social, and civic positions.

These transitions can be even more challenging for the family headed by a single parent. Approximately 21 million children, approximately 28% of children in the United States, lived with one parent in 2012, most typically the mother. The single most significant health risk in families headed by a single mother is poverty. In 2012, nearly one in two children whose mother was the sole head of the household were found to be living below the poverty level. Comparatively, 70% of children who lived with two married parents

were in households that were at least 200% above the poverty level (US Census Bureau, 2013). Inadequate resources make it extremely difficult for middle-aged mothers, who are frequently raising grandchildren as well, to fulfill their responsibilities.

Families with young adolescent or young adult children have been described in research studies as both *postparental* and *launching families.* In contrast, criticism of this emphasis on the separation of children (regardless of age) from their families is increasing. Gilligan (1982) criticizes the work of many human development theorists who identify human development in terms of separation from the family. Apter (1990) also challenges the conventional view that adolescent girls must reject their mothers as part of a healthy development. Middle-aged parents are encouraged to continue to care for and nurture their adolescent and adult children while recognizing the increasing interdependence of their relationships.

By supporting their children's efforts, parents can increase the self-esteem of their children while being effective role models. The parent assumes less of a parent-child relationship while interacting more on an adult-to-adult level. As the children are "launched," the parents may have uninterrupted time alone and time to share activities. Family life may also be threatened by older children living at home, opposition to a child's partner, or the inability to establish satisfactory relationships with potential or actual partners or sons-in-law and daughters-in-law. For many parents, the idea of their children leaving home is anticipated with relief that the heavy care responsibilities of parenting are over or with dread over having to fill the void of time and inactivity. The **empty nest syndrome** may be exacerbated if the husband and wife have never learned to communicate effectively and to enjoy each other's company without the children.

At the other end of the family spectrum, aging parents can place demands on the adult child primarily because older adults are frequently beset with health problems. A caring relationship is in order, in which the aging parent's need for independence is recognized.

Because of society's emphasis on youth, the middle-aged adult must

associate feelings of self-worth with personal integrity rather than with body appearance or physical prowess. Friends of both sexes can provide invaluable support systems. With the newly found free time after children have left home, the middle-aged adult can share favorite activities and learn new ones. Middle-aged adults should remind themselves how much and how well they are doing, especially considering the complexity of the demands placed on them. Never before in history have families pursued such varied and individual-oriented goals as they do today.

Although for many Americans the concept of family remains of major importance, the perceptions are different from those held by previous generations. Parents and children in most families are involved in numerous activities, as evidenced by a "let's-hurry-or-we'll-be-late" orientation. Even younger children frequently have schedules that must be met if they are to get to their dance, drama, play, or enrichment classes. None of these activities necessarily have a negative effect, but the cumulative influence places heavy demands on all family members. Additionally, many activities in which both children and adults are involved have a certain degree of competitiveness. For example, parents frequently become emotionally involved in the athletic activities of their children to the extent that the failure of a 6-year-old to play a winning softball game causes a great deal of parental anguish. One only has to listen to the cheering of parents at a Little League baseball game to note whose self-esteem is at stake. Shouts of "Kill her," "Grab the third baseman," and so on do not tend to engender feelings of team spirit or a notion of playing for the sake of having a good time (Erikson & Erikson, 1998).

Work

Perhaps the most common role that middle-aged adults share is that of a worker. Much of their pride and sense of satisfaction is derived from their work. Work is equated with being "grown up." One can easily recall the "What do you want to be when you grow up?" questioning of youth. Success and achievement are evaluated in terms of careers and family life. The work ethic still persists, especially for

individuals born during the Great Depression and for many of their offspring as well. Much of their conversation evolves from what they do, such as "My name is Leslie Smith. I am a real estate agent." To be mature is to be a responsible, hard-working individual (Erikson & Erikson, 1998). Research has shown that middle-aged adults are more satisfied with their jobs than are younger adults.

Middle-aged adults constitute most of the American workforce. For many, vocations play a major role in defining personal levels of wellness. There were approximately 2.9 million nonfatal workplace injuries and illnesses in 2015. The 2015 rate continues a pattern of annual decline over the last 13 years. Employers reported nearly 48,000 fewer nonfatal injury and illness cases in 2015 compared to 2014 (US Department of Labor, Occupational Safety and Health Administration, 2016b). The highest rates of nonfatal injuries occur in construction, manufacturing, and health services. Thirty percent of nonfatal injuries and illnesses requiring days away from work continue to be due to overexertion and repetitive motion (Nicholson, 2011).

A total of 4836 workers died from a work-related injury in the US during 2015, the highest annual figure since 2008. Nearly 20% of the fatally-injured workers were employed in the private construction industry (US Department of Labor, Occupational Safety and Health Administration, 2016a). More than 22% of workplace fatal injuries involved motor vehicles; other causes included falls, nonvehicular injuries, blows, and electrocutions. In decreasing order, workers in mining, agriculture, forestry, fishing, construction, and transportation are at an increased risk of dying from a work-related injury (Nicholson, 2011; US Department of Labor, Occupational Safety and Health Administration, 2010). Poor housekeeping and poor design predispose workers to falls and other accidents; exposure to noise and toxic chemicals also make employees susceptible to injury and illness. Many injuries that contribute significantly to the morbidity and mortality of adults can be prevented. Fixing faulty steps, repairing faulty electrical wires, and securing carpets are only a few of the many preventive measures.

Accidents are twice as common among smokers than among nonsmokers. Possible explanations include the loss of attention, the use of one hand for smoking, and irritation of the eyes. Other work-related problems include exposure to harmful substances resulting in lung diseases, cancers, and workplace violence (Box 23-7: Quality and Safety Scenario).

Box 23-7

Quality and Safety Scenario

Lifetime Prevention of Cardiovascular Disease in Women

- **Eat a healthy diet** with fruits, vegetables, whole grains, and fat-free or low-fat milk and milk products. Choose foods low in saturated fats, cholesterol, salt (sodium), and added sugars.
- **Exercise regularly.** Adults need 2 hours and 30 minutes (or 150 minutes total) of exercise each week. You can spread your activity out during the week, and can break it up into smaller chunks of time during the day.
- **Be smoke-free.** If you are ready to quit, call 1-800-QUIT-NOW (1-800-784-8669) or 1-855-DÉJELO-YA (1-855-335-3569 for Spanish speakers) for free resources, including free quit coaching, a free quit plan, free educational materials, and referrals to other resources where you live.
- **Limit alcohol use,** which can lead to long-term health problems, including heart disease and cancer. If you do choose to drink, do so in moderation, which is no more than one drink a day for women. Do not drink at all if you are pregnant.
- **Know your family history.** There may be factors that could increase your risk for heart disease and stroke.

- **Manage any medical condition** you might have. Learn the **ABCS** of heart health. Keep them in mind every day and especially when you talk to your health provider:

- **Appropriate aspirin therapy** for those who need it.
- **Blood pressure control**
- **Cholesterol management**
- **Smoking cessation**

The effect of life events on mental health depends on the personal strength of the individual, the availability of supports, and the nature and number of events and their significance for the person. Three common examples of life events with potential disruptive effects are marital separation or divorce, having two or more jobs, and caring for aging parents. Their negative effects may be alleviated if assistance is provided early in the process of a change. In some organizations, resources for managing problems of addiction, life transitions, emotional issues, financial problems, stress reduction, and grief counseling are available off-site to all employees. These resources are offered without cost to the individual and, in some cases, to their family members or support persons.

Two-or-More-Job Family: Family and Work Responsibilities

More and more women are in the workforce for their own financial well-being or that of their family, especially with the increased cost of living, health care insurance, and college expenses and the decreased

availability of employer-sponsored pension. Other women, who are postmenopausal and have launched their last child, have a newfound freedom and begin to rediscover themselves, sometimes through a new career. The husband may be a support person in this venture or he may feel threatened by his wife's new pursuits. These role changes and life transitions can be stressors to the family.

The balance between marital status, with or without children at home, caring for older parents, and employment obligations can significantly affect the psychological well-being of the woman in her middle years. In recent years, changes in family patterns with adult children moving back into their parents' home, sometimes with their offspring, bring new challenges to relationships, resources, and responsibilities within the home.

Historically, women worked with their husbands within the family farm or business. Only in the few decades immediately after World War II did many middle class white women stay at home while their husbands went to work. Currently, women make up a significant portion of the workforce. Additionally, many women have become highly educated and motivated to pursue careers. Both men and women are increasingly taking jobs that do not end at 5:00 p.m. The problems and challenges of the workplace are experienced at home as adults bring projects and problems home with them.

Job-related travel has also increased during the last few years for both men and women. Travel by either partner means additional responsibilities for the one who remains at home. Additionally, if one spouse travels far more than the other travels, feelings of resentment may develop, or the common ground for discussion of work events may be altered. The one who stays at home may feel “put upon” when the spouse is perceived as having fun. In contrast, travel is tiring and is not usually as exciting as it appears to observers. The traveling spouse can come home tired and irritable and desire peace and quiet, which may conflict with the expectations of other family members.

Men may feel threatened by highly successful and visible women. For some families the post–World War II prototype was for the husband to support the family financially and gain status through

achievements of work outside the home. As women gain recognition and acclaim for their career accomplishments, even the most "enlightened" man may experience twinges of envy and discomfort. Men have few role models to learn how best to be a participant in a successful two-career family. Men may need as much, if not more, support than women in adapting to contemporary family styles. Opportunities to discuss what it means to be a man in today's society can be helpful, such as in support groups with volunteers or professionals who provide services to various agencies and community resources.

In addition to the changes in women and the effect on families of each adult working at one or more jobs, the nature of the parental work environment is critical to family coping ability. Work that is emotionally draining, particularly when it is filled with conflict, poses special threats to family stability. When parents come home tired, angry, or frustrated from their experiences at work, they likely have limited emotional support to share with other family members. When people gain self-esteem from their jobs and generally enjoy going to work, they tend to experience less frustration and dissatisfaction with themselves and their positions, enabling them to give more of themselves to other members of the family.

Middle age is important when one is looking at the career clock. Issues that need to be considered include midcareer changes and preretirement planning. Retirement is a major turning point; to many people, it is the transition from middle age to old age and the period of work to the period of leisure or different work.

Adults are working up to and beyond the age of retirement. Many are entering new careers later in life because they are living longer and are in need of more financial resources to successfully enter the older adult years. As adults progress through the middle years, they become increasingly aware of the time remaining until retirement: "Can I readjust my goals?" "Is there disparity between where I am in my career and where I would like to be?" An example might be the 60-year-old veteran nightclub singer whose goal to record a solo album remains to be achieved. The heightened awareness of age and

the decreased likelihood of finding another suitable job can precipitate increased anxiety or depression in this singer.

Comprehensive health-promotion programs at the work site contain these elements: “health education that focuses on skill development and lifestyle behavior change in addition to information dissemination and awareness building, preferably tailored to employees' interests and needs; supportive social and physical work environments, including established norms for healthy behavior and policies that promote health and reduce the risk of disease, such as work site smoking policies, healthy nutrition alternatives in the cafeteria and vending services, and opportunities for obtaining regular physical activity; integration of the work site program into the organization's administrative structure; related programs, such as employee assistance programs; and screening programs, preferably linked to health care service delivery to ensure follow-up and appropriate treatment as necessary and to encourage adherence. Optimally, these efforts should be part of a comprehensive occupational health and safety program” (US Department of Labor, Occupational Safety and Health Administration, 2010).

Caring for Aging Parents

The needs of aging parents and of the middle-aged adult's own children can create additional demands during the middle years (Figure 23-1). The middle-aged adult can feel caught between the children and the parents. Both children and older parents can present unrealistic, excessive demands and be difficult to please.

FIGURE 23-1 Middle-aged adults, young adults, and older adults can enjoy meaningful relationships with one another.

Middle-aged adults may be faced with having frail and ill parents live within their own family unit or placing them in a nursing home. These dilemmas are complicated by the reality that their parents are growing older and may not have long to live. The recognition of the parents' impending death heightens middle-aged adults' awareness of their own aging and mortality.

Difficulties in caring for older parents can be somewhat lessened when potential situations are discussed before a crisis arises. This is particularly true when all members of the middle-aged adult family are working, space in their home is limited, and the community has few resources for the well or ill older adults. Although institutionalization is undesirable to many families, the care of ill, older parents may eventually require it. By anticipating these needs and preparing for them, middle-aged adults and their parents can develop further meaningful relationships with one another.

Divorce

Divorce is a major disruption to the marriage and family and to each individual's short-term and long-term health. As the divorce rate has risen in recent years, individuals and families have been challenged to find solutions to new and multiple problems. When a divorce occurs,

each family member must confront the necessity to examine and, in many cases, modify an accustomed style of living and adapting.

In the early 1970s, Wallerstein and colleagues (2000) began a longitudinal study of 131 children of divorced parents through extensive interviews with the children and their parents. The children are now adults with families of their own. The most significant findings of this ongoing study are the long-lasting, cumulative, and demonstrative effects of divorce, which continue for decades. Although Wallerstein found healing in adults is more or less complete 3 years after divorce, this is not so for the children, who experience the divorce differently from their parents.

Some of the limitations of Wallerstein's research are anecdotal methods versus double-blind interviews; the children are primarily white, educated, and upper middle class; and the findings are not differentiated from those of high-conflict families, nor are distinctions made between the influences of conflict that caused the divorce and the actual divorce itself. Continuing research is being done to illuminate these initial findings on the long-term effects of divorce. Sumnera (2013) suggests that parental midlife divorce also impacts children who are adults at the time of parental separation. Therapeutic interventions that assist adult children of divorced parents to reconcile the divorce experience of their parents should be offered and available.

Death

Similarly to divorce, death of a spouse can result in grieving for the loss of companionship and the loss of an anticipated future free from the responsibilities of work and children. The surviving spouse may be unprepared to be single again, to be the only parent, or to live alone. The loneliness may be exacerbated by ill or dying peers or parents. Middle-aged adults become increasingly aware of the finite nature of life, thinking not only of the number of years since birth but also of the number of years left to live. The midlife review is a common outcome of this recognition.

Sexuality-Reproductive Pattern

Research suggests that a high proportion of men and women remain sexually active well into later life (Lochlainn & Kenny, 2013). Men and women can continue to have a satisfactory pattern of sexual functioning throughout the middle and older adult years. As they would in any other developmental phase, middle-aged adults may need counseling to make health-promoting decisions about their sexual and reproductive behaviors and health.

Unintended pregnancies are high across all ages of American women but are highest (77% of all pregnancies) in middle-aged women. Fertility begins to decline for women between 35 and 40 years of age; however, perimenopausal women are still at risk of an unintended pregnancy (Nelson, 2011). Nearly 30% of pregnancies in women older than 35 years are unintended (Godfrey et al., 2011). Upson and colleagues (2010) found that 14% of women aged between 35 and 44 years failed to use a contraceptive at the last sexual intercourse and that the rate of unprotected intercourse nearly doubled for women aged between 40 and 44 years. In contrast, women planning to have children during the fourth and fifth decades of life should know that fertility rates decrease and infant mortality rates increase, especially when mothers are aged 45 years or older. In 2013, fetal mortality rates for women aged 45 years or older were more than twice the rate for women aged 25 to 29 years (MacDorman & Gregory, 2015).

The pregnancy-related mortality rate for all women in the United States was 17.8 deaths per 100,000 live births in 2011 as compared with 7.2 deaths per 100,000 live births in 1987. Research indicates that an increasing number of pregnant women in the United States have chronic health conditions such as hypertension, diabetes, and chronic heart disease that increase the risk of complications. Considerable racial disparities in pregnancy-related mortality exist. In 2011, the pregnancy-related mortality rates were 12.5 deaths per 100,000 live births for white women, 42.8 deaths per 100,000 live births for black women, and 17.3 deaths per 100,000 live births for women of other races (MacDorman & Gregory, 2015). Achieving the *Healthy People*

2020 target goal of reducing maternal deaths will require that national, state, and local policies address women's needs before and during pregnancy, and that gaps in research and prevention programs be identified through improved monitoring.

Changes in the reproductive systems of men and women result in changes in sexual function throughout adulthood. During middle adulthood, sexual arousal is slower, orgasms are less intense, and a return to pre-arousal levels is more rapid, with men having longer refractory periods between erection and ejaculation. When a person continues to be sexually active, these functional changes occur over decades and are minimally noticeable until later in adulthood, unless external factors are present, such as the negative effects of some antihypertensive and antidepressant agents.

After menopause, many women enjoy sex more, especially because the risk of pregnancy no longer exists. Conversely, menopause can bring many challenges to a woman. American culture values women largely for their youth, beauty, and childbearing ability. Middle-aged women may confront their own aging for the first time and may be perplexed as to the symptomatic factors and possibly changing roles. Women can experience vaginal dryness, difficulty finding a partner, less interest in initiating sex, and longer times to reach orgasm. However, perceived emotional closeness during sex was found to be associated with more frequent arousal, lubrication, and orgasm (Trompeter et al., 2012).

Although men and women frequently enjoy satisfactory sexual relationships throughout the middle adult years, men in their middle age are more vulnerable to sexual dysfunction than are women. Erectile dysfunction, the inability to attain or maintain an erection sufficient enough for sexual activity, is a common disorder among older men. The gradual decline of age-related physiological function combined with chronic comorbidities may impair erectile function (Hockenberry & Masson, 2015). Common disorders related to erectile dysfunction include cardiovascular disease, diabetes, lower urinary tract symptoms, and depression—all of which should be considered by health care providers when assessing middle-aged men

experiencing erectile dysfunction. Several readily available, nonsurgical treatments for erectile dysfunction exist: medications, supplements, hormonal therapy, penile injection, and external vacuum devices. The successful treatment of erectile dysfunction has the potential to increase sexual performance satisfaction, intimacy between partners, and overall quality and satisfaction with life. Although the risk of pregnancy is no longer a concern for middle-aged consenting adults, improved sexual function may increase the frequency of sexual activity and perhaps with more than one partner. Health care providers should not hesitate to initiate a sexual wellness assessment with middle-aged adults. Discussions should include specific sexual wellness strategies designed to prevent sexually transmitted infections.

Abnormal genital bleeding and secondary amenorrhea are common gynecological conditions that indicate serious physical problems. Abnormal genital bleeding is the most common reason for gynecological office visits by adult women. Although pregnancy and menopause are the most common causes of secondary amenorrhea, other conditions related to abnormal pregnancy, functional disorders, physiological changes, and pathological factors must be considered (Eliopoulos, 2010).

As for adolescents and young adults, sexually transmitted diseases continue to be a major public health problem for middle-aged adults. Women and children bear an inordinate share of the burden: sterility, ectopic pregnancy, fetal and infant deaths, birth defects, and mental retardation. Virtually all cases of cervical cancer are caused by human papilloma virus (HPV), and just two HPV types, 16 and 18, are responsible for approximately 70% of all cases (NIH, National Cancer Institute, 2015a). As with many other health behaviors and diseases, the full effect on the life of an individual and the family may not be realized until middle age.

Adults in middle age have many of the same HIV/AIDS risk factors as younger people, but they may be less aware of their risk. In 2014, people aged 50 years or older accounted for 17% (7391) of an estimated 44,073 HIV diagnoses in the United States. Of these, 44%

(3242) were among those aged 50 to 54 years (CDC, 2017d). More than 50% of new HIV infections occur as a result of people who have HIV but do not know it (CDC, 2016e). The actual numbers may be higher because HIV/AIDS is often misdiagnosed, underreported, and undertested in this population. Middle-aged Americans are more likely to receive a diagnosis of HIV infection later in the course of their disease, which can lead to a poorer prognosis and shorter survival after an HIV infection diagnosis (CDC, 2017d).

Nearly three-fourths of all people currently with HIV/AIDS in the United States are men. In 2015, gay and bisexual men accounted for 82% of the estimated HIV diagnoses among men and 67% of the estimated AIDS diagnoses in the United States (CDC, 2016f). Among all gay and bisexual men who received an HIV diagnoses in the United States in 2015, African American accounted for the highest number (10,315; 39%), followed by whites (7,570; 29%) and Hispanics/Latinos (7013; 27%) (CDC, 2017c). Transgender women who have sex with men are among the groups at highest risk of HIV infection, followed by injection drug users, who remain at significant risk of getting HIV. The US Preventive Services Task Force now recommends HIV screening for adolescents and adults between 15 and 64 years, those who engage in risky behaviors, and all pregnant women, including those who present in labor whose HIV status is unknown (USPSTF, 2013).

Coping–Stress Tolerance Pattern

Kobasa (1979) was the first to investigate the concept of stress hardiness. She identified hardiness as an aspect of personality which included control, commitment, and challenge. Her theory is clinically relevant because it suggests hardiness acts as a mediator between perceived stress and self-efficacy across many dimensions: physical, psychological, mental, and emotional. According to Kobasa, individuals who demonstrate hardiness, across the health continuum, appear to be more resistant to the effects of stress.

Stress is an unavoidable human life experience that triggers a reactive physiological response often derived from perceived

psychological stressors. The many negative effects of perceived stress on physical health are well documented. Physiologically, stress causes the hormones cortisol, epinephrine, and norepinephrine to activate or exacerbate a number of conditions, including chronic physical, mental, and comorbid health conditions (Manchanda & Madan, 2014; Vranceanu et al., 2014). Stress tolerance is a learned behavior. More than 35 years ago, Benson first described the "relaxation response" as a reproducible state of deep rest (Benson & Klipper, 1975). The immediate and long-lasting effects of stress can be mitigated with effective coping skills including holistic mind-body interventions such as meditation, yoga, tai chi, and deep breathing (Manchanda & Madan, 2014; Wang et al. 2014). Evidence-based research demonstrates how the mind-body connection helps individuals to cope with a wide range of illnesses and stressful life events (Box 23-8: Innovative Practice).

Box 23-8

Innovative Practice

Benson-Henry Mind Body Institute of Massachusetts General Hospital, Harvard Medical School Mind/Body Medical Symptom Reduction Programs

Research demonstrates that 60% to 90% of health care visits are for symptoms such as headaches, insomnia, weakness or fatigue, and gastrointestinal symptoms, all of which are frequently stress related. The Mind/Body Medical Symptom Reduction Programs are designed to help individuals who have chronic illnesses (including life-threatening illnesses) or stress-related symptoms to better manage their health problems and optimize their quality of life. The interventions combine conventional medical care with knowledge of the effects of behaviors and attitudes on health. The following are included in the biopsychosocial-spiritual approach of the assessment

and treatment plans:

- Eliciting the relaxation response, a state of deep rest that changes responses to stress (decreases vital signs and muscle tenseness, increased mindfulness)
- Enhancing coping skills through cognitive-behavioral strategies
- Encouraging exercise or physical activity
- Providing nutritional counseling
- Monitoring and adjusting medication, when necessary, in consultation with the physician

Insurance claims for these outpatient visits are submitted directly to each person's insurance carrier. Because health insurance policies differ, coverage and reimbursement differ. An advocate helps persons seeking care research their specific health insurance coverage and billing requirements. Research demonstrates the following results may occur after these interventions:

- Persons with pain reduced their number of physician visits by 36%.
- Visits to a health maintenance organization were reduced by approximately 50% after a relaxation response–based intervention, resulting in significant cost savings.
- Blood pressure was lowered and use of medications decreased in 80% of hypertensive persons; 16% were able to discontinue all of their medications.
- Sleep patterns were improved for 100% of persons with insomnia; 90% reduced or eliminated the use of sleep medication.
- Infertile women reported decreased levels of depression, anxiety, and anger, along with a 35% conception rate.

- Women with severe premenstrual syndrome experienced a 57% reduction in physical and psychological symptoms.
- Health-promoting behaviors, such as nutrition, social supports, self-esteem, health responsibility, and exercise, increased after the program and were maintained by the 6-month follow-up visit.
- Six months after the program, 80% of persons continued to experience reduction of their physical symptoms.
- Anxiety and depression normalized for most participants and were maintained for 6 months following the program.
- Women with menopause reported fewer hot flashes, lower blood pressure, improved sleep, and decreased depression, anxiety, and anger.

In a 45-year longitudinal study of 173 men, Vaillant and his colleagues (Vaillant, 2003; Vaillant & Vaillant, 1990) found that the extent of tranquilizer use before age 50 years was the most powerful negative predictor of both mental and physical health outcomes at age 65 years. Another important predictor for health outcomes was the maturity of defenses against stress such as sublimation, anticipation, altruism, and humor.

Stress and Heart Disease

As reiterated throughout this chapter, heart disease is the second leading cause of death in the middle-aged adult. In landmark studies, Haynes and colleagues (1978, 1980) described the relationship of psychosocial factors to coronary heart disease using the Framingham study. In the study, 24 measures of psychosocial stress were used. In men, aging worries correlated significantly with systolic and diastolic blood pressure. Marital disagreement and personal worries correlated significantly with diastolic blood pressure. Both diastolic and systolic pressure correlated significantly with work changes and anxiety in

employed women between 45 and 64 years of age. Anger suppressed, anger discussed, tension, and anger symptoms correlated significantly with diastolic blood pressure in this age group.

Among white-collar men in this age group, the Framingham type A and ambitiousness scales also correlated significantly with elevated diastolic blood pressure. The correlation of anger symptoms and anger discussed with diastolic pressures was significant for white-collar women aged between 45 and 65 years. The initial findings of Haynes and her colleagues have been supported by many other studies, including those of Spielberger and colleagues (1983), Kawachi and colleagues (1996), Williams and colleagues (2000), and Sanchez-Gonzalez and colleagues (2015).

The death of a parent enhances awareness of one's vulnerability to illness and death. The more opportunities and time people have to prepare for these stressful events, the more likely they will be to feel in control and the less likely they will be to feel anxious and helpless. When individuals assume more responsibility for their life, decisions lead to concrete behaviors, such as drafting a will, developing an advance directive (which includes **living will, health care agent,** and granting a durable power of attorney), and making funeral prearrangements. An **advance directive** is a legal document prepared when an individual is alive, competent, and able to make decisions to provide guidelines for health care providers in the future, when the individual is not able to make decisions because of physical disability (being unconscious) or mental incompetence. By granting a **durable power of attorney,** the individual designates another person (spouse, son, daughter, or friend) to make health care decisions (especially about how aggressive treatment should be in forestalling death) when an individual becomes unable to make such decisions. The nurse helps middle-aged adults anticipate stressors so that they are better prepared to cope with and to prevent additional physical, psychosocial, and spiritual stressors, thereby optimizing their health.

Values-Beliefs Pattern

When adults make decisions affecting their lives, this is usually the

result of a personal, complex pattern of values and beliefs. Much of what people value or believe to be true is formed early in life and can be the most difficult to alter. Usually, people do not spend a great deal of conscious thought on abstract explanations of the meaning of life and why certain things are valued. However, during times of illness or crisis, most people will take time to review their value systems and seek meaning about what is important.

A crisis at any age can be a turning point during which both increased vulnerability and increased potential are present. When the crisis is managed successfully, a virtue or strength will evolve. Erikson and Erikson (1998) identified *caring* as a middle-aged adult virtue that is often developed during times of crisis.

Committed responsibilities for the care and welfare of others promote moral development. When middle age is lived with generativity, many opportunities are afforded to live life by one's higher principles. The middle-aged adult can differentiate among personal wants and needs, duties demanded by society, and principles by which to live. Kohlberg's work on moral development delineated these phases as conventional and postconventional. His studies of men described stage 3 as an interpersonal definition of morality, whereas stage 4 is a societal definition based on law and order. Kohlberg concludes that most American adults are in these phases of moral development. In contrast, stage 5 is the concern and willingness to sacrifice oneself for the well-being of others (Kohlberg & Lickona, 1986). Subsequent studies by Gilligan (1982) on moral development in women and men demonstrate sex differences when describing high morality. Women discussed issues of selfishness versus responsibility, of exercising care with decision-making, and avoiding hurting others. Men described terms of *justice, fairness,* and *rights of individuals.* Gilligan (1982, 1990) concluded that women possess a process of moral development different from that of men.

Valuing others, having relationships, and being responsible to others enable middle-aged adults to make the transitions of moral development. This process is accomplished through raising children, developing more junior employees, and serving the community. As

people fulfill these commitments, they increasingly treat others as equals and gradually develop a sensitivity and desire to change barriers to human worth and equality such as racial prejudice, homelessness, inadequate access to health care, and the availability of stockpiles of weapons.

Environmental Processes

Environmental factors are significant variables in health promotion. Cleanliness in home, work, and school environments helps control the spread of infectious diseases such as influenza. The effect of handwashing in controlling illness cannot be overstated. In a larger context, continued efforts at improving sanitation and controlling pollution (air, water, noise) will result in a reduction of health problems such as lung disease, transmission of bacterial and viral infections, and hearing loss.

Because there are approximately 100 million workers in the United States, occupational hazards are a serious threat to national health. Exposures to toxic chemicals, asbestos, coal dust, cotton fiber, ionizing radiation, physical hazards, excessive noise, and stress can precipitate numerous health problems (USDL, 2012). For the middle-aged worker, these problems include cancers, lung and heart diseases, decreased hearing, physical injuries, and mental health problems (USDL, 2010).

Physical Agents

Ionizing radiation is a physical agent that can cause cancer. One example of this is cancer caused by medical procedures that include the use of diagnostic radiography and therapeutic radiation.

Water pollution has become another major concern. Many industrial and agricultural wastes, such as benzene and chlordane, have been recovered in rivers and lakes from which drinking water is obtained. These substances can potentially lead to carcinomas and other health problems.

Air pollution from automobile emissions, burning fuels, and industrial incineration has warranted smog alerts and air pollution indices. This issue is especially important to the individual with chronic respiratory or cardiovascular disease (USDL, 2010).

Noise pollution in industry is a potential problem for the middle-

aged adult worker. Hearing loss is the most common occupational disease, but it can be prevented if federal guidelines are followed with regard to noise exposure levels and hearing conservation programs, especially prevention activities aimed at miners and construction workers, for whom hearing loss is a major problem. Exposure to excessive noise, radon, radiation, sunlight, and vibration can produce problems such as chronic obstructive lung disease, cancer, and degenerative diseases (Nissenbaum et al., 2012).

Biological Agents

As noted throughout this text, health and disease are influenced by the interactions among the agent, host, and environment. Agent factors can be biological, physical, chemical, or psychological. The biological causes of diseases include bacteria, viruses, rickettsiae, fungi, parasites, and food poisoning. Because these causes are often limited to identifiable occupations, they can be readily diagnosed, treated, and prevented. Many of these agents are transmitted through the air or by contact with certain media, such as water, food, blood, or feces.

Hepatitis A is caused by viral infection, with transmission occurring primarily through the fecal-oral route. This host-agent interaction typically occurs in the middle-aged adult living in an environment with poor sanitation and having close contact with an infected person. The person may also be exposed through contaminated food and water. The Hepatitis B viral agent is transmitted primarily in the blood or plasma of the infected individuals, which is particularly significant for the adult who is employed in a health care setting. Among medical and dental personnel (with surgeons, oral surgeons, and pathologists at the highest risk), the risk of contracting hepatitis B is six times higher than that of the general population.

There are two other infections that are of particular concern for middle-aged adults: pneumonia and varicella/herpes zoster ("shingles"). Both can be prevented through vaccinations, which adults aged 60 years or older are advised to receive (CDC, 2017e).

Chemical Agents

Chemicals include a wide variety of substances that increase the risk of morbidity and death in the middle-aged adult. When a home is located near an industry, there is the risk of exposure to toxic chemicals that pollute the air. Contaminants can also be carried home on the clothing from the workplace.

Workers at increased risk include coal miners, wood handlers, and those who work with asbestos and coke. Pneumoconiosis is found in approximately 15% of coal miners, with "black lung disease" implicated in 2430 deaths in 2005 (the *Healthy People 2020* target is a 10% reduction). Wood handlers have increased risk of certain cancers. The asbestos worker has an increased risk of mesothelioma and asbestosis. Approximately 2 million workers each year are exposed to benzene and vinyl chloride, which may be carcinogens. Among American industrial workers, 9 in 10 may be inadequately protected from exposure to at least 10 of the 163 most common hazardous chemicals. More than 2000 of the 50,000 chemicals found in the workplace are suspected human carcinogens (USDL, 2012).

Tobacco

Cigarette smoking is the leading cause of preventable death, disease, and disability in the United States. In 2014 an estimated 40 million adults in the United States smoked cigarettes. Currently, 18.8% of men and 14.8% of women in the United States smoke. Adult smoking rates differ across the Unites States, but the states with the most smokers are in the Midwest and Southeast (CDC, 2016c). Among Americans, cigarette smoking, and exposure to second hand smoke, is responsible for more than 480,000 premature deaths annually: 278,544 deaths annually among men and 201,773 deaths annually among women (CDC, 2016g). Smoke recipients are at increased risks of heart disease as well as colds, chronic bronchitis, emphysema, and cancers of the mouth, lungs, esophagus, pancreas, and bladder. Many 50-year-old adults have a 30-plus-year history of cigarette smoking. The life expectancy for smokers is at least 10 years less than that of

nonsmokers; however, quitting smoking before the age of 40 years reduces the risk of dying of smoking-related disease by approximately 90% (CDC, 2016g).

Few smokers realize that cigarettes contain 2000 known chemicals, including tar, nicotine, hydrogen cyanide, formaldehyde, and ammonia. Cigarette smoking is, for most smokers, an addiction to nicotine, which is absorbed into the bloodstream. Nicotine acts on the two divisions of the nervous system: central (brain and the spinal cord) and peripheral (autonomic nervous system and motor and sensory fibers to the arms and legs). The effects of nicotine stimulation can be observed both in electroencephalographic changes and in hand tremors. Nicotine also stimulates the heart, leading to an increased pulse rate and elevated blood pressure. Although smokers frequently believe that cigarettes have a calming effect, this notion is misleading. Nicotine stimulates the body, whereas carbon monoxide causes lethargy. Smokers may feel calm, although they are actually having their sensations dulled by carbon monoxide. Additive effects such as those from chlorine, cotton dust, and γ-radiation can lower midexpiratory flow values. Profound effects can also be observed with asbestos interaction.

Determinants of Health

Social Factors and Environment

Culture is a set of beliefs, practices, norms, customs, rituals, and assumptions about life that are first learned from one's parents and extended family during the early years of socialization (Spector, 2012). Spector further relates the ways in which one's cultural background is a component of one's ethnic background.

Nurses understand the potential influences their own ethnic cultures have on those of others. The middle-aged adult may not interpret dizziness as a possible symptom of hypertension; for example, it may be described simply as a spell. The black adult's definition of health may be completely different from that of the white health care provider or the Asian person. The obese adult who has received positive reinforcement throughout life for being pleasingly plump is less motivated to lose weight than is the adult who defines health as being svelte.

The health problems of middle-aged adults, even within major ethnic groups, are varied. Recent immigrants who live in crowded urban areas have higher mortality rates than do earlier immigrants of the same cultural group who live in healthier environments. Immigrants' working conditions continue to be poor, with long hours and minimal wages. Modern preventive health care is difficult, if not impossible, to obtain.

Poverty rates are important indicators of community well-being and the health status of community members. According to the 2007 to 2011 American Community Survey, 42.7 million people, or 14.3% of the US population, had income below the poverty level. By race, the highest national poverty rates were for American Indians and Alaska Natives (27.0%), followed by blacks (25.8%). The poverty level for whites was 11.6% (US Census Bureau, 2013). Economic adversity, disproportionate access to health services, and cultural differences may contribute to lower life expectancy and the disproportionate disease burden for American Indians and Alaska Natives. The

American Indian life expectancy (73.7 years) is still more than 4 years less than that for the US general population (78.1 years). Death rates are significantly higher in many areas for American Indians compared with the US general population, including those for chronic liver disease and cirrhosis, diabetes mellitus, unintentional injuries, assault/homicide, intentional self-harm/suicide, and chronic lower respiratory disease (USDHHS, Indian Health Service, 2015).

Culture also determines acceptable gender-specific and age-specific attitudes and behaviors. Accepted gender-specific attitudes and behaviors associated with life-defining rituals (birth, marriage, illness, and death) are particularly important for stabilizing and preserving one's culture. Aging confers vast decline and compromise for both sexes. Middle-aged adults who conform to stereotypical patterns of expected role behaviors often receive continued communal support and reverence even as their health status and abilities decline. Conversely, those who choose not to conform to expected changes in behaviors and roles risk exclusion, isolation, loneliness, and compromised health. Nurses who have attained cultural competency can ensure that appropriate health promotion is provided, especially for vulnerable populations and those individuals, families, and communities who have special health care needs (Box 23-9: Diversity Awareness).

Box 23-9

Diversity Awareness

Health Care for Middle-Aged Gypsies

Culturally competent and effective health care is imperative for all, especially people with several comorbid conditions who do not have a consistent primary care provider or clinic. Middle-aged gypsies, or Roma, are in need of consistent health care. The Roma are a large vulnerable population in Europe. However, because they tend to travel from one place to another and do not put down roots, health providers need to understand their beliefs so the episodic interactions

will be most productive. Barriers to adequate care delivery include affordability of care, lower self-reported health, and higher death risks. The Roma population is very distinctive in its use of language, community, family, and cultural traditions. It is important to realize the Roma prefer to involve their family when it comes to their health. Hence a family member should be allowed to participate in each interaction with a health provider. Involvement of the family will increase the person's adherence to the health regimen.

From Cook, B., Wayne, G. F., Valentine, A., Lessios, A., & Yeh, E. (2013). Revisiting the evidence on health and health care disparities among the Roma: A systematic review 2003–2012. *International Journal of Public Health*, *58*, 885–991.

Levels of Policy Making and Health

Adults in the middle years are frequently at the peak of their careers. Although their net income may be greater than it was during early adulthood, they frequently have significant additional financial obligations. For many individuals in their late 50s or early 60s, retirement is a life stage they have dreamt about and anticipated for years (Figure 23-2). Leaving full-time employment for a less strenuous daily routine may not be possible for many middle-aged adults. A number of reasons are offered to account for this relatively new trend:

FIGURE 23-2 Middle-aged adults may enjoy travel after retirement.

- The high quality of health care in the United States provides technological advances that extend the limits for life expectancy. Individuals are living longer than previous generations, and therefore they cannot "afford" to retire in their mid-50s to early 60s because they have a financial need to "fund" another 25 to 30 years of life.
- Quality health care is expensive. The costs of health care are mounting because research and development expenses associated with medical treatments, including pharmaceuticals, are escalating. When an illness has been diagnosed, individuals expect "the best" type of care and interventions, which, in turn, influences the financial burden borne by almost all Americans.
- Changes in the American economy in the past 10 years have necessitated significant changes in family patterns. Increasingly, more than one generation lives together in the same home so as to afford the rising costs of commodities that have been taken for granted. For example, the costs of a college education funded by middle-aged adults are not necessarily balanced by a full-time

position at the end of the 4 or 5 years needed to obtain a college degree. Young adults are not leaving home at 22 or 23 years of age. Consequently, their parents, if still employed, must continue to work to support adult children and also to pay the debt of the college educational experience.

- Individuals may have accrued increasing debt to pay for health insurance that is becoming more costly. As people develop health conditions that are related to accumulated stress and the aging process, they require more use of their benefits from their health insurance companies. In addition, they may be supporting elderly parents, whose health conditions have consumed their savings and home investment to pay for their parents' medications, hospitalizations, and/or nursing home expenses. When the adult or family members have ongoing health problems, the economic status of the family can be compromised further (see Box 23-9: Diversity Awareness).
- Unemployment statistics show an increasing rate of unemployment across the United States. When people lose their jobs, they are often without health insurance, and when they develop illness or conditions that are associated with the middle years, they rely on their savings or must resort to less expensive housing. Such changes can cause extreme mental strain and possibly lead to mental health problems. The individual's economic status plays a role in the incidence of mental illness, with higher rates of anxiety, depression, and phobias evident in adults at the lower socioeconomic level.
- Technological changes have opened opportunities for individuals to work at home and/or remote sites. These extensions of the workplace often necessitate individuals to change their routines, and to take educational courses to keep current with job requirements, or to be competent to take on more responsibilities. Training to increase skills or knowledge can be expensive and often must be funded by the individual.

Health Services/Delivery System

Numerous agencies are geared to providing information and other resources for the middle-aged adult. These can be categorized as official, voluntary, and service agencies. Councils of community services frequently publish a directory. Official agencies include those that are state and federally funded, such as public health departments and drug treatment centers. Voluntary agencies include the American Heart Association, the American Cancer Society, the American Lung Association, and Alcoholics Anonymous. Many educational and self-help programs are sponsored by these organizations. The American Lung Association sponsors a "Stop Smoking" program, which can be conducted on a group basis in a work or community setting. Service agencies include professional organizations, such as state nurses' associations, the American Medical Association (sponsor of the Tel-Med program), bar associations, Young Men's Christian Association (YMCA), hospice programs, and the Women's Occupational Health Resource Center. The Affordable Care Act of 2010 is a law with provisions (Internal Revenue Service, 2012) that meet one of the primary objectives of *Healthy People 2020;* that is, increasing access to health care for all Americans. The implications of this statute are most significant for middle-aged adults who are currently uninsured and/or have preexisting health conditions. Preventive screening will allow individuals to receive testing for the detection of cancer and other conditions that can influence initiation of treatment at an earlier stage of illness. Thus the financial expense of treatment will potentially be less and the stresses on the individual and family considerably eased. In addition, costs for unemployment benefits where individuals work will be reduced.

From another perspective, the Affordable Care Act has already expanded coverage for individuals younger than 26 years who are still carried on the health insurance policy held by their parents. This provision is particularly relevant for young adults who are still in college or who have not found employment after college graduation. The economic impact of unemployment among this age group on families with middle-aged parents described in the previous section cannot be understated (Jarrett, 2012). Specific details of the Affordable

Care Act of 2010 may be found at
http://www.irs.gov/newsroom/article.

Nursing Application

Interventions focused on health promotion span the gamut for nurses working in the community or on location at work sites. Consequently, there are many ways nurses interact with middle-aged adults.

Individuals in this middle-age range will likely need the services of a professional nurse *several times* before they reach their 60s. They may meet a nurse when seeking care for themselves in a physician's office or primary care center. As a parent, they are likely to accompany their school-age child or their own elderly parent to the emergency department to obtain care for a sports-related injury or trauma following a fall. In the employment realm, some individuals will have their initial experience with a nurse through a pre-employment evaluation visit. As a company employee, the same person may receive first aid for a minor injury or have his or her blood pressure monitored periodically by a nurse working in the occupational health department.

If the individual needs surgery or hospitalization, they may meet a home health nurse after discharge. Nurses are also available in rehabilitation settings to instruct and coach people regarding lifestyle changes following a heart attack or other acute events. Community health nurses provide health-promotion activities such as senior health fairs that include “flu clinics” where adults are vaccinated against influenza. Life events such as the death of a partner, sudden unemployment, or disability may cause anxiety, depression, or other stress-related symptoms. Nurses who specialize in mental health can provide counseling and other forms of treatment for grief support or mental disorders resulting from trauma or sudden losses.

In a variety of settings, nurses are health educators. For example, the nurse who works in the community or in occupational health initiates events that raise awareness to identify health risks among middle-aged adults. She teaches strategies for controlling symptoms and accepting responsibility for changing potentially dangerous health habits. These interventions can be provided on a one-to-one or

group basis or as a lecture presented in a health seminar.

The target groups identified by occupational health nurses frequently have common needs for information, interventions, and periodic monitoring. The following are common concerns in the workplace: exposure to chemical or toxic substances, tobacco and substance abuse and addiction, and ongoing problems with fatigue attributable to frequent changes in scheduled shifts.

The occupational health nurse has a wide range of responsibilities. For example, he or she may evaluate patterns of absenteeism to identify a source for infection that is affecting a group of employees. The nurse participates in policy development focused on preventing or reducing the incidence of work site injuries or incidents. In another instance, the nurse provides clarification of Occupational Safety and Health Administration (OSHA) regulations when new machinery is incorporated into operation. The nurse is wise to invite a broad spectrum of employee participants to join a company safety committee. Their primary purpose is focused on keeping the work site safe for employees. Strategies to achieve that objective include determining health hazards that exist in each department of the company and developing or refining procedures that promote safety, such as creating policies that address infection control or procedures for fire drills. If the nurse has certification from the American Heart Association, he or she can offer classes in cardiopulmonary resuscitation and use of the automated external defibrillator.

The scope of practice for community health nurses (CHNs) differs from state to state. They may be employed by a city or town, or derive their authority through the state health department. The role of the CHN focuses on health promotion and disease prevention for a population living in a specific area. The CHN interfaces with nurses working in the municipality and surrounding areas such as in medical offices, state health department offices, hospitals, urgent care clinics, schools, emergency services, YMCA/Young Women's Christian Association (YWCA), and local businesses. Frequently, lectures or demonstrations are sponsored by the CHN at the request of service organizations in communities such as the Lions or Kiwanis Club. The

CHN may combine efforts with nurses who volunteer as parish nurses. Together they may present an annual health fair or senior health fair to serve a broad scope of health-information needs of the local community. The features of the fair would include 15 to 20 displays that offer some of the following—all on a single occasion: demonstrations in the use of car seats and seat belts; short presentations on fall prevention; screening measures to identify risk factors for heart disease, cancer, and diabetes; town planning guides for emergency preparedness; massage therapy for stress reduction; informational guides for the regional poison control center; and "flu shots" against influenza for anyone who desires one. Such events allow the CHN to generate interest and enthusiasm among people who are interested in improving the health and well-being of residents living in their local community.

Health-promotion strategies will become more widely recognized as the objectives and target goals of *Healthy People 2020* are incorporated into health plans supported by health insurance policies, employers, wellness programs, and health care providers. With the passage of the Affordable Care Act in 2010, accessibility and utilization of health care services, especially for minorities, are expected to increase. Nurses will be in leadership roles to organize and implement early detection and screening programs. They will survey communities and identify needs of the specific populations, and evaluate the effectiveness of public health measures already in place. They will be called on to develop educational programs and create on-line information sites that disseminate current medical research findings to the public showing how changes in lifestyle behaviors can positively influence health outcomes. Progress toward the target goals of *Healthy People 2020* can be incorporated in these websites or blogs so that the American people can see, and learn first-hand, how important changes in their own lifestyle will affect the overall health of the United States.

In summary, better health and enhanced well-being of the American people are expected outcomes of health promotion. The *Healthy People 2020* objectives and target goals provide the framework

and direction for improving health awareness and practices among US residents.

In this chapter, health needs and potential diseases and conditions relevant to middle-aged adults have been addressed along with strategies to mitigate symptoms, prevent complications, and foster well-being. Normal changes expected with the aging process were also presented. Selected objectives and target goals of *Healthy People 2020* were compared with findings published for outcomes of *Healthy People 2010.* In addition, the impact of social processes, such as relationships, family, work, values and belief systems, disability and death, and finances, completed the discussion.

Nurses provide important strategies for fostering health promotion. They are employed in most settings where middle-aged adults live, work, play, and raise their families. Because of this integral position in society, nurses are highly influential in identifying health concerns, organizing interventions, and evaluating the effectiveness of program outcomes. *Healthy People 2020* is presented as one approach for health professionals to use in their mission to improve the health and well-being of the American people.

The Occupational Safety and Health Administration (OSHA) mandates that the employee have a healthy and safe work environment. Therefore a complete health history is essential. Is there a history of hypertension, arthritis, cancer, or hernia? Is there significant family history? Is the person a smoker? How many packs per day are smoked? Does the person take medications? Medical limitations must be addressed; for example, decreased visual acuity means no driving, and dermatitis means no skin exposure to oils, chemicals, or solvents. Removing a worker from a particular job may be indicated if the worker might endanger coworkers, if the worker has a disease condition that might be aggravated by the job, or if the worker is taking prescribed medications with potentially harmful side effects.

The nurse in the community and in industry should reiterate key safety directives to the middle-aged adult. For example, wear seat belts and observe speed limits, use only hands-free phone

communication, and avoid texting while driving. The middle-aged adult's reaction time is also decreasing, which reinforces the need for periodic driving testing as recommended by the National Highway Traffic Safety Administration.

With an increase in leisure time, the middle-aged adult is at greater risk of recreational accidents. As noted, moderation should be stressed. Alcohol is a depressant and should be avoided in activities that require attentiveness.

Protection from burns is essential; 56% of fatal residential fires are directly related to cigarette smoking while in bed. Falls can occur at any age; safety measures should be considered for the entire family, including specific preparatory planning for the very young and aging parents. A few suggestions to the middle-aged adult might be to avoid highly waxed floors, correct poor environmental lighting, avoid high beds, and avoid bathtubs lacking nonslip bottoms.

Handgun availability is controversial at best; however, approximately 20% of American households have handguns. When the person believes strongly that it is necessary to have a firearm, safety measures to avoid accidental injury should be discussed, such as security locks and proper storage.

The Occupational Safety and Health Act (1970) was designed to ensure that workers are employed under safe and healthy working conditions. The act is applicable to every employer who is engaged in a business that affects commerce. The employer must ascertain that the workplace is free from recognized hazards and must comply with the act. The OSHA has offices in most major cities and can provide recommended standards for occupational agents.

Nurses can participate actively in the safety committee of the industry in which they are employed. When no such committee exists, many protection measures will fall on the nurse. The following are some suggestions:

- Tour the facilities on a regular basis. Be familiar with resource books, laws, and codes.
- Develop a toxicology chart with symptoms of overexposure and recommended treatment. Update this chart frequently.

- Be a role model in safety issues; wear safety glasses, protective footwear, and gloves; and do not smoke.
- Discuss the pre-employment physical examination with the employee, with an emphasis on risk factors. Monitor health problems and exposure levels in the work setting.

The worker must be aware of the protective clothing that should be worn, sanitation measures for the work environment, general hygiene measures, and proper immunization. The food handler, for instance, should have an annual tuberculosis skin test, wear clean clothing and appropriate hair protection, and use good handwashing techniques. The nurse should not assume that workers know how to protect themselves and others.

Since 1996, the National Occupational Research Agenda has become the research framework for the National Institute for Occupational Safety and Health and the nation. Partners work together to identify, research, and address the most critical issues in workplace safety (http://cdc.gov/niosh/about.html).

A major challenge for the nurse is to encourage workers to assume responsibility for protecting their own health. Increasingly, organizations are interested in promoting the health of their employees for many reasons, including enhancing their recruiting efforts and minimizing lateness, absenteeism, turnover, physical and emotional inability to work, disability costs, and health and life insurance costs. Health-promotion programs are increasingly recognized for their vital contributions to the financial viability of organizations.

Health-promotion programs within an organizational setting can be categorized in one of three levels: awareness, lifestyle change, and supportive environment. The goal of a health program, at the level of awareness, is to increase the individual's knowledge or interest in a particular health issue, such as smoking cessation. Examples of awareness programs include special events, flyers, lunch seminars, meetings, and newsletters. Changing health behaviors or status is not the goal of awareness programs, but is the goal of lifestyle change programs.

Lifestyle change programs last at least 8 to 12 weeks and include assessment, education, and evaluation components to help individuals implement long-term modifications in health behavior and experience the results of their instituted changes. To maintain these long-term changes and to develop a healthy lifestyle, a supportive organizational environment is needed. This type of environment may include health-promoting physical settings, corporate policies and culture, ongoing programs, and employee ownership of programs.

Case Study

Caregiver Role Strain: Ms. Sandra A.

Sandra, a 47-year-old divorced woman, received a diagnosis of stage 3 ovarian cancer 4 years ago, for which she had a total hysterectomy, bilateral salpingo-oophorectomy, omentectomy, lymphadenectomy, and tumor debulking followed by chemotherapy, consisting of cisplatin (Platinol), paclitaxel (Taxol), and doxorubicin (Adriamycin). She did well for 2 years and then moved back to her hometown near her family and underwent three more rounds of second-line chemotherapy. She accepted a less stressful job, bought a house, renewed old friendships, and became more involved with her two sisters and their families.

Sandra developed several complications, including metastasis to the lungs. Then she could no longer work, drive, or care for herself. She had been told by her oncologist that there was nothing else that could be done and that she should consider entering a hospice. She met her attorney and prepared an advance directive and completed her will. She decided to have hospice care at home and, with the help of her family, set up her first floor as a living and sleeping area. She was cared for by family members around the clock for approximately 3 days. Sandra observed that she was tiring everyone out so much that they could not really enjoy each other's company. At this time, she contacted the Visiting Nurse Association (VNA) to seek

assistance. Her plan was to try to enjoy her family and friend's visits. After assessment, the VNA nurse prioritized her problems to include fatigue and caregiver role strain. Other potential problem areas that may need to be incorporated into the care plan include anticipatory grieving and impaired comfort.

Reflective Questions

- What are some of the stresses on Sandra's middle-aged sisters and their families?
- What resources are available to manage these stresses and support the sisters while caring for their dying sister Sandra?
- Describe Sandra's feelings about dependency and loss of autonomy because she is unable to do her own activities of daily living any longer.

Care Plan

Caregiver Role Strain: Ms. Sandra A.

***NURSING DIAGNOSIS: Risk of caregiver role strain related to sister's terminal cancer**

Defining Characteristics

- Sandra's sisters are weary from doing all of the daily care for Sandra.
- Sandra and her family are at a point where they are accepting her terminal status.
- Sandra and her family want to prepare for a death at home.

Related Factors

- The sisters are missing work and neglecting their own families.
- The sisters need assistance to care for Sandra as she continues to become compromised.

Expected Outcomes

- Sandra and her sisters will contact the VNA to assist in planning daily hospice care at home.
- The VNA and the family will plan realistic care.
- Sandra will have quality time with her sisters and friends as her condition allows.
- The sisters will be able to voice their grief and anger about Sandra's upcoming death.

Interventions

- Home health aides are scheduled for 24 hours a day.
- A psychiatric nurse practitioner will meet Sandra and her family to schedule therapy time for anticipatory grieving.
- The sisters will attend a support group for families involved in hospice care at home.
- A schedule will be made to allow each sister time at home, one-on-one time with Sandra, and time for rest.

---

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the

diagnoses listed in this work.

Summary

Nurses help middle-aged adults improve their quality of life, both for the present and for the future, through the identification of risk factors, health promotion, and other nursing interventions. Nurses work in a variety of health care settings available to middle-aged adults: outpatient clinics, occupational health clinics, and private practice.

Health promotion and disease prevention are aimed at the personal habits and lifestyles of adults to improve their biological, spiritual, and psychosocial development. The strategies to help an adult achieve a higher level of health include individual and group counseling based on identified risk factors, providing self-help information that is most relevant to the middle-aged adult, and describing available resources. Using these strategies, the nurse can motivate middle-aged adults to prioritize their own health and quality of life for the individual middle-aged adult, including it as a prerequisite for their own present and future health and particularly preceding the responsibilities in promoting the health and quality of life of younger and older generations. After years of poor health practices, adults can make changes that reduce their risk of disability from chronic disease and promote functioning and quality of life.

Older Adult

Jeanne Merkle Sorrell

OBJECTIVES

After completing this chapter, the reader will be able to:

- Discuss how the population of older adults has changed in recent years.
- Describe health-promotion activities specifically targeted to older adults.
- Discuss various theories of aging.
- Discuss *Healthy People 2020* objectives as they relate to health promotion for older adults.
- Describe how normal aging changes in the older adult relate to health-promotion strategies.
- Discuss nutritional factors that promote healthy living for the older adult.
- Discuss preventive strategies related to risk factors that could lead to health problems in older adults.
- Describe health-promotion strategies for the five most prevalent health conditions and the five leading causes of death among older adults.
- Discuss how health-promotion activities can impact problems related to environmental, physical, biological, and chemical agents that contribute to disability, morbidity, and death in later adulthood.
- Analyze social and political issues that influence the well-being of older adults.
- Identify major resources for healthy living that are available for older adults.

KEY TERMS

Activities of daily living
Alzheimer disease
Atrophy
Cognition
Decubitus ulcer
Delirium
Dementia
Depression
Euthanasia
Glaucoma
Health literacy
Impotence
Influenza
Instrumental activities of daily living
Life review
Mild cognitive impairment
Mini-Mental State Examination
Nutritional screening
Osteoporosis
Physician-assisted suicide
Polypharmacy
Postoperative cognitive dysfunction
Presbycusis
Presbyopia
Reminiscence
Restless legs syndrome
Sclerosis
Social portfolio

Stress incontinence

Theories of aging

Urge incontinence

Think About It

Older Adult Smokers

You are the director of a senior center in which 10 of your 40 members smoke. Several of the smoking individuals currently experience health problems. One older woman has chronic obstructive pulmonary disease and avoids using her oxygen because she is not supposed to smoke while the oxygen tank is in the room. One older man has high blood pressure; lung cancer has been diagnosed in another one of the smokers. As director of the center, you would like to help these older adults to stop smoking. You have referred them to their physicians to obtain assistance with smoking cessation. All involved are on limited incomes and cannot afford to pay the charge for either a behavior-management class or nicotine-replacement therapy.

- What additional information do you need to determine the potential efficacy of a smoking cessation program in your center?
- What types of resources are available to help you obtain the necessary assistance for these smokers?
- What provisions are available under Medicare and the Affordable Care Act of 2010 to assist a person with smoking cessation?
- What policy changes might be instituted within the senior center to prevent secondhand smoke from harming the residents in the center's care?

There is a popular poster featuring an older man with an impressive muscular physique that is obviously the result of hours and hours of working out. The poster's title carries a strong message: “Aging is not

for sissies." Because older adults are living longer and healthier as a result of health-promotion and technological advances, health care professionals often enjoy the gift of caring for older adults who are active and still making important contributions to society. To be caring for a group of human beings that was virtually nonexistent 100 years ago is truly extraordinary. It is important to help ensure, however, that these individuals are not only living longer but also that their lives are fulfilling and lived in dignity with as much independence as possible.

Who is the older adult today? Older adults are living longer and working longer. In 2014, 23% of men and approximately 15% of women 65 years or older were still working (Mather, 2016). According to preliminary data from the US Census Bureau, an individual who was 65 years of age in 2010 could expect to live 19.2 years more, for a total of 84.2 years. Individuals aged 85 years in 2010 could expect to live an average of 6.6 years more, for a total of 91.6 years (Murphy et al., 2012).

The older adult population is also becoming more racially and ethnically diverse. The percentage of white Americans in the population of adults aged 65 years or older is expected to decrease during the next 30 years, whereas the percentages of black Americans, Hispanics, and Asian Americans will continue to rise. By 2044, it is projected that more than half of Americans will belong to a minority group, with almost one in five being foreign born (US Census Bureau, 2015b). Considering this shift in population characteristics, nurses need to develop an awareness of the cultural diversity of this population and identify the cultural beliefs that influence their health care decisions.

There are many positive changes for older adults today. This share of the population is much better educated and more proficient in using technology than in the past. In 1965 only 5% of older adults had completed a bachelor's or higher degree, and by 2014 this had increased to 25% (Mather, 2016). Also, the gap in life expectancy of the sexes is narrowing, with the gap between men and women decreasing from 7 years to less than 5 years between 1990 and 2013 (Mather,

2016). The poverty rate for older adult Americans has also decreased significantly from approximately 30% in 1966 to 10% today (Mather, 2016). More older adults are "aging in place" in the community, with new living options that include retirement communities and independent living facilities or assisted living facilities, as well as skilled care institutions.

On the other hand, there are new challenges for health promotion in older adults. Obesity rates are increasing, and there are widening economic disparities across minority groups. In 2014 the percentage of Latino and black American older adults who lived in poverty was more than double the percentage of non-Hispanic whites (Mather, 2016). There has also been an increase in divorce rates, and more women are living alone. Forty-two percent of women aged between 75 and 84 years are living alone; the proportion jumps to 56% for women aged 85 years or older (Mather, 2016). All these changes have implications for health-promotion planning and interventions.

In 2013, approximately 44.7 million Americans (14.1% of the population) were 65 years or older (US Census Bureau, 2015a). By 2060 the number of adults aged 65 years or older is expected to be 98.2 million, with 19.7 million aged 85 years or older (US Census Bureau, 2015b). The 65 years or older population is expected to increase from 15% today to 24% by 2060 (Mather, 2016). Adults aged 85 years or older are the fastest-growing group within the older adult population, which means that nurses in the community, acute care settings, and long-term facilities will increasingly be caring for these individuals. Women comprise approximately four-fifths of the centenarians (Health Editor, 2016). Many factors have come together to help older adults live longer and healthier. These include continued vaccination development, injury prevention, decrease in smoking, less air pollution, and health-promotion activities (Health Editor, 2016).

During the past few decades, older adults have used the most health care dollars in the last 7 years of their lives, tending to wait until they became sick before seeking health care. Health care providers focused more on illness care than wellness care, resulting in a high prevalence of illness and limited health-promotion

interventions. Misconceptions surrounding health promotion for older adults can impede the ability of nurses and other health providers to provide care that will enhance healthy aging. These misconceptions need to be overcome so that older adults receive health-promotion interventions that help to keep them active and healthy.

Health promotion is as important in later adulthood as it is in childhood. Older adults derive the same benefits from health-promotion activities as do their younger counterparts; they are not "too old" to stop smoking, start exercising, change their diet, or relinquish other bad health habits. Specific health-promotion strategies may differ for the young old (55–75 years), the middle old (75–85 years) and the very old, or oldest old (85 years or older). For example, strength training may be very appropriate for the young and middle old groups but may not be feasible for the oldest old. Balance exercises need to be addressed especially for those in the older two age groups. The potential for improvement with all groups is great, and nurses have a key role in changing common societal misconceptions and in creating new understandings regarding health promotion for older adults.

The diversity of cultural backgrounds in the United States influences the many biological, psychological, social, and economic changes as well as the spiritual and life transitions associated with aging that will be discussed in this chapter. Older adults who have immigrated to the United States have brought with them different languages, spiritual and cultural beliefs, eating preferences, and views about health and illness that may seem strange to younger Americans. Furthermore, people of different cultures may value older adults differently on the basis of their cultural perspective. Many cultures view older adults as a source of family and cultural history and wisdom. Throughout this chapter, cultural norms and behaviors will be discussed within each functional health pattern.

Healthy People 2020

In 2005, halfway through the *Healthy People 2010* project period, a midcourse review of the status of the national objectives was conducted. Data were collected to measure the progress of the goals and to revise and reword the goals to make sure they were accurate and scientifically relevant. Through this process it was determined that many goals focusing on older adults were being met. Importantly, the life expectancy continues to increase and the quality of life continues to improve throughout the nation. The number of years in good or better health and the number of years free of activity limitations and chronic illness have also increased slightly. At the same time, it was determined that new goals, topic areas, and topic-specific objectives needed to be developed. In December 2010 the US Department of Health and Human Services (USDHHS, 2010) released *Healthy People 2020.* The overall goals of *Healthy People 2020* expanded on previous goals and are to:

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

As part of the development of *Healthy People 2020,* several new topic areas were added, several of which focus on the health and wellness of older adults. These new topic areas are dementias, including Alzheimer disease; health-related quality of life and well-being; health care–associated infections; sleep health; and a unique category—older adults—which recognizes the special needs of this population. Selected national health-promotion and disease-prevention objectives for the older adult are listed in Box 24-1: *Healthy People 2020*. These

objectives focus on increasing health-promotion programs and decreasing morbidity and mortality related to various disease states. In addition, other specific topic areas provide objectives that address the needs of older adults. Some of these will be addressed later in this chapter.

Box 24-1

Healthy People 2020

Selected National Health-Promotion and Disease-Prevention Topics and Objectives Relevant for Older Adults

Older Adult

- Increase the proportion of older adults who are up-to-date on a core set of clinical preventive services.
- Increase the proportion of older adults with one or more chronic health conditions who report confidence in managing their conditions.
- Increase the proportion of older adults who receive diabetes self-management benefits.
- Reduce the proportion of older adults who have moderate to severe functional limitations.
- Increase the proportion of older adults who engage in light, moderate, or vigorous leisure-time activities.
- Increase the proportion of the health care workforce with geriatric certification.
- Reduce the proportion of noninstitutionalized older adults with

disabilities who have an unmet need for long-term services and supports.

- Reduce the proportion of unpaid caregivers of older adults who report an unmet need for caregiver support services.
- Reduce the rate of pressure ulcer–related hospitalizations among older adults.
- Reduce the rate of emergency department visits attributable to falls among older adults.
- Increase the number of states, including the District of Columbia, and tribes that collect and make publicly available information on the characteristics of victims, perpetrators, and cases of elder abuse, neglect, and exploitation.

Dementias, Including Alzheimer Disease

- Increase the proportion of persons with diagnosed Alzheimer disease and other dementias, or their caregivers, who are aware of the diagnosis.
- Reduce the proportion of preventable hospitalizations in persons with diagnosed Alzheimer disease and other dementias.

Hearing and Other Sensory Communication Disorders

- Reduce the proportion of adults who have elevated hearing thresholds, or audiometric notches, in high frequencies (3, 4, or 6 kHz) in both ears, signifying noise-induced hearing loss.
- Increase the proportion of adults bothered by tinnitus who have seen a physician or other health care professionals.

- Increase the proportion of adults for whom tinnitus is a moderate to severe problem who have tried appropriate treatments.
- Increase the proportion of adults with balance or dizziness problems in the past 12 months who have ever seen a health care provider about their balance or dizziness problems.
- Increase the proportion of adults with moderate to severe balance or dizziness problems who have seen or been referred to a health care specialist for evaluation or treatment.
- Reduce the proportion of adults with chemosensory (smell or taste) disorders who as a result have experienced a negative impact on their general health status, work, or quality of life in the past 12 months.
- Increase the proportion of persons with communication disorders of voice, swallowing, speech, or language who have seen a speech-language pathologist for evaluation or treatment.
- Increase the proportion of persons with communication disorders of voice, swallowing, speech, or language who have participated in rehabilitation services.

Sleep Health

- Increase the proportion of adults who get sufficient sleep.

Respiratory Diseases

- Reduce activity limitations among adults with chronic obstructive pulmonary disease.
- Reduce deaths from chronic obstructive pulmonary disease among adults.
- Reduce hospitalizations for chronic obstructive pulmonary disease.

- Reduce hospital emergency department visits for chronic obstructive pulmonary disease.
- Increase the proportion of adults with abnormal lung function whose underlying obstructive disease has been diagnosed.

Vision

- Reduce visual impairment.
- Increase the use of personal protective eyewear in recreational activities and hazardous situations around the home.
- Increase vision rehabilitation.
- (Developmental) Increase the proportion of federally qualified health centers that provide comprehensive vision health services.

As the population of older adults continues to increase, the cultural diversity within this population will also increase. Cultural background and race have an effect on the prevalence of disease in the United States. A 2011 National Healthcare Quality and Disparities Report noted that despite some improvements, inequities persist among racial and ethnic minority groups (Agency for Healthcare Research and Quality, 2012). Researchers found a serious disparity in health care quality for blacks (41%), Hispanics (39%), and Asians (30%) as compared with whites. Language barriers are also associated with decreased quality of care, as well as decreased safety. The report emphasized the need to step up measures to increase quality and access to health care so as to achieve equitable health care for all.

Biology and Genetics

Although there is a serious need to promote the health of the older population, there are numerous challenges in meeting this need. One of the great challenges to health promotion for older adults lies in the misconceptions about the benefits of disease prevention and health promotion. Another challenge relates to the difficulty in separating normal changes of aging from pathological processes and illness. Age-related changes are frequently regarded as inevitable and irreversible. However, there is a large amount of variability in age-related changes within each individual. Environmental, economic, physiological, genetic, psychological, social, and cultural factors combine to influence the aging process. Many older adults have an interest in learning about their genetic makeup and how this may influence their aging process and development of disease. Box 24-2: Personal Genomic Testing provides information about personal genomic testing.

Box 24-2

Genomics

Personal Testing

Older adults are increasingly interested in learning about their own DNA to find clues about their heritage and about factors that may affect their future health. With technological developments in recent years, it is now possible to purchase low-cost genetic kits for as little as $100. Do the results of these tests prompt older adults to change their habits to more healthy lifestyles?

In the United States, three companies have dominated the market for do-it-yourself, direct-to-consumer (DTC) genetic kits that allow consumers to bypass medical intermediaries: 23andMe, Navigenics, and DeCODEme. These genetic tests offer a wide array of information

about ancestry, physical traits, and health information. (Ancestry.com does not provide health information at this time). Health-related genetic tests include predictive tests for alterations in genes known to be strongly associated with disease onset (e.g., Alzheimer disease and several cancer syndromes), along with susceptibility tests that give feedback of much lower increased risk of developing common health conditions (e.g., type 2 diabetes).

Bioethicists and health researchers have raised concern about the health-risk genre of these tests, and the Food and Drug Administration asked 23andMe to stop marketing the health tests until it could provide evidence that their results are reliable. Those who favor DTC health-related testing argue that direct access to personal genetic information is a fundamental right and helps to preserve autonomy and privacy by eliminating health care intermediaries. Others argue that providing genetic information directly to consumers without health professional support to explain the information could result in numerous harms, in that consumers may not have adequate information to make determinations about the meaning of the results. There is concern that individuals who are told they carry genetic risk variants may have harmful psychological responses, such as feeling fatalistic about their potential to reduce their risk of health problems. Early users of the DTC kits, however, have not reported strong emotional response to test results, regardless of whether or not the findings show increased risk.

An important advantage of DTC testing is the potential that the results could motivate consumers to make lifestyle changes to reduce their disease risk. Consumers state that genetic susceptibility tests for conditions such as obesity would motivate them to adopt a healthier lifestyle and could also provide information that could help their primary care provider monitor their health.

Very few studies have evaluated whether individuals change their lifestyle after receiving genetic risk results. Early evidence suggests, however, that thus far genetic test results have not had a demoralizing effect on consumers' efforts or desire to change health habits. There is mixed evidence on how susceptibility testing may

influence use of health services. The bottom line is that when consumers receive the results of their testing, they often find that their personalized risk results are matched with the same health recommendations they already know. Most experts believe that potential breakthroughs that could enable genomic risk information to be used routinely to prevent disease and foster healthy aging are still in the future.

From McBride, C. (2015). Personal genomic tests for healthy aging: Neither feast nor foul. *Generations. Journal of the American Society on Aging*. http://www.asaging.org/blog/personal-genomic-tests-healthy-aging-neither-feast-nor-foul.

Most researchers agree that biological changes show that growth and development peak during early adulthood, with subsequent linear decline until death. These normal changes must be distinguished from pathological changes to focus health-promotion interventions on behaviors that can be changed. For example, it is normal for older adults to experience a decline in their respiratory vital capacity. Therefore when nurses are recommending exercise programs, older people must start gradually, allowing them to experience the exercise free from respiratory distress. Selected changes will be discussed specifically in the Gordon's Functional Health Patterns section.

Another challenge in promoting the health of older adults relates to the prevalence of chronic illness and multiple health problems. Although chronic illness is not a normal part of aging, years of environmental assault, poor health behaviors, and stress have placed older adults at a high risk of developing these illnesses. Table 24-1 lists the percentage of older adults with chronic conditions. Illness influences the older adult's capacity and motivation to learn new behaviors, so health-promotion activities need to be individualized to fit functional abilities. According to the Centers for Disease Control and Prevention (CDC, 2014a), in 2013 61.1% of adults aged 65 years or older had difficulty in performing at least one basic action or had a complex activity limitation. Most of these limitations are associated with physical changes of aging and chronic disease such as arthritis,

heart disease, stroke, and respiratory disease. The prevalence of preventable illness and the concomitant physical limitations associated with chronic disease clearly indicate that there is a great need for health-promotion and disease/injury-prevention activities in this population. It is important to note that health-promotion practices among older adults may vary because of the individual's self-perception of health status and the individual's economic and cultural background (Box 24-3: Diversity Awareness).

TABLE 24-1

Average Percentage of People Aged 65 Years or Older Who Have Chronic Health Conditions

Chronic Condition	Age 65–74 yr	Age ≥75 yr
Hypertension	54.2	57.3
Arthritis	49.0	54.1
Heart disease	16.5	25.8
Cancer	20.4	27.2
Diabetes	22.0	21.7
Asthma	8.7	7.4
Chronic bronchitis or emphysema	11.4	12.6
Stroke	6.1	10.7

From Centers for Disease Control and Prevention, National Center for Health Statistics. (2010). Summary health statistics for U.S. adults: National Health Interview Survey 2010. http://www.cdc.gov/nchs/data/series/sr_10/sr10_252.pdf.

Box 24-3

Diversity Awareness

Perceptions of Health Status, Need for Assistance With Routine Needs, and Need for Assistance With Activities of Daily Living Related to Race

Data from the National Health Interview Survey conducted by the CDC in 2010 (CDC, National Center for Health Statistics, 2010) provide interesting information about the perceptions of Hispanic,

non-Hispanic black, and non-Hispanic white older adults regarding their health status, their need for assistance with routine activities, and their need for assistance with activities of daily living.

When asked about health status, 42.7% of white adults 65 years or older stated that their health was excellent or very good, 34% described their health as good, and 22.9% described their health as fair or poor; 44% of Asian American older adults reported their health as excellent or very good, 34.4% stated their health was good, and 21.6% stated their health was fair or poor. In contrast, 25.3% of black older adults reported their health as excellent or very good, 36.4% stated their health was good, and 38.2% stated that their health was fair or poor. Of Hispanic older adults, 28.1% reported that their health was excellent or very good, 33.8% reported their health as good, and 38.2% stated their health was fair or poor. In all groups, those who described their health as fair or poor were also more likely to be financially poor, with 40% of white older adults, 51.6% of black older adults, 53.4% of Hispanic older adults, and 45.6% of Asian American older adults who reported their health status as fair or poor also being financially poor.

Respondents were also asked about their need for assistance with activities of daily living, such as bathing, showering, dressing, eating, getting in and out of the bed or chair, using the toilet, or getting around inside the home; and their need for assistance with routine activities, such as performing everyday household chores, doing necessary business, shopping, and getting around for other purposes outside the home. The results indicated that 11.2% of non-Hispanic white older adults reported needing assistance with routine needs, 18.1% of Hispanic and 17.1% of non-Hispanic black older adults reported needing assistance, and 6.2% of non-Hispanic white older adults reported needing assistance with activities of daily living, whereas 11.5% of both Hispanic and non-Hispanic black older adults reported needing assistance.

Nurses must be aware of racial disparities in the incidence of chronic disease, perceived health status, and perceived need for assistance with activities of daily living and routine tasks in the

people for whom they provide care. Assessing older adults holistically and planning interventions that focus on health promotion, illness and injury prevention, and effective management of chronic illness will help to ensure improved quality of life for all older adults.

From Centers for Disease Control and Prevention, National Center for Health Statistics. (2010). Summary health statistics for U.S. adults: National Health Interview Survey 2010. http://www.cdc.gov/nchs/data/series/sr_10/sr10_252.pdf.

Theories of Aging

The study of how and why people age has continued over many years and has been the source of a great deal of debate. For many years, the cause of death on many older adults' death certificates was listed simply as "old age." At the 55th Annual Meeting of the Gerontological Society of America, Butler and Olshansky (2002) explored this mind-set in a presentation entitled "Has Anyone Ever Died of Old Age?" As the specialization of gerontology has progressed, researchers have clarified the physiological, social, and psychological reasons related to why people die.

There is no formula to predict how a person will age or how long that individual will live. Many **theories of aging** continue to be examined today, including those regarding metabolism, free radicals, stress, the role of the immune system, genetics, epigenetics (the blending of nature/genetics and nurture/environment), and diet. It is postulated that genetic markers may predict the development of disease and play a large role in determining how a person will age and how long the person will live. In addition, researchers report that calorie-restricted diets have resulted in an increase in longevity in animals; however, there is debate regarding whether calorie restriction alone or calorie restriction in the presence of genetic markers increases longevity. The role of antioxidants in binding free radicals is also being researched as an important influence on increasing longevity. Although no consensus has yet been reached that describes the entire aging process, exciting theories continue to be forthcoming (National Institute on Aging, 2011). Some of the theories

used to explain aging are briefly described in Box 24-4.

Box 24-4

Theories of Aging

Biological Theories of Aging

- Programmed theories of aging: Aging is the result of predictable cellular death.

- Immunity theory: Aging is a programmed accumulation of damage and decline in the function of the immune system resulting from oxidative stress.

- Neuroendocrine control/pacemaker theory: Aging is a programmed decline in the functioning of the nervous, endocrine, and immune systems. The cells lose their ability to reproduce.

- Gene theory: Longevity may be associated with a genetic trait or a "longevity gene," "juvenescent" genes mediate youthful vigor and mature adult well-being, "senescent" genes promote functional decline and structural deterioration.

- Error theories of aging: Aging is the result of an accumulation of random errors in the synthesis of cellular DNA and RNA.

- Oxidative stress theory (free radical theory): Errors

are a result of random damage from free radicals.

- Cross-linkage theory: Aging is a product of accumulated damage from errors associated with cross-linked proteins where cross-linked proteins become stiff and thick.

- Wear-and-tear theory: Cellular errors are the result of deterioration over time because of continued use.

- Calorie restriction theory: In animal models, calorie restriction increased the life span and the health of the animals.

Sociological Theories of Aging

- Activity theory: Continued activity is an indicator of successful aging.

- Disengagement theory: In the course of aging, the individual slowly withdraws from former roles and activities.

- Role theory: The ability of an individual to adapt to changing roles throughout life is predictive of adjustment to the changing roles associated with aging.

- Continuity theory: In normal aging, personality remains consistent. Personality influences role activity and life satisfaction.

- Age stratification theory: Focuses on the relationship between age as an element of social structure and aging people as a cohort.

- Subculture theory: Older people have their own norms, habits, and beliefs and interact better among age peers than with other age groups.

Developmental Theories of Aging

- Erikson's developmental theory: There is a predetermined order of development, and specific tasks are associated with specific periods in a person's life. For older adults, the developmental stage is integrity versus despair.

- Peck's developmental theory: This theory expanded on Erikson's theory with identification of discrete tasks of late life that when accomplished together result in ego integrity.

- Havighurst's developmental theory: There are specific tasks associated with aging, including adjusting to the losses of aging (e.g., health, income, death of spouse and age peers), adapting to change and new roles, and accepting life's experiences.

- Tornstam's theory of gerotranscendence: Aging is viewed as the movement from birth to death and maturation toward wisdom. Gerotranscendence involves achieving wisdom through personal transformation.

Gordon's Functional Health Patterns

Health Perception–Health Management Pattern

Motivation is an important factor in maintaining health. Nurses who care for older adults know that the best nursing in the world cannot make an individual do something he or she believes to be unnecessary. A primary factor in the older adult's motivation to promote personal health is the perception of health and its subsequent management. For older adults who have always been healthy and then receive a diagnosis of a serious disease, it is important that they find ways to promote health while living with the disease. For example, new research shows that many of the debilitating aspects of Parkinson disease can be minimized through active exercise, including bicycling (Paddock, 2012). Older adults with a diagnosis of spinal stenosis or back pain that prevents them from walking long distances may think they can no longer travel. New mobile devices such as scooters, which allow the person to ride through the airport and then check the scooter at the gate, help to make travel to visit friends or family or dreamed-of adventures possible. These devices also provide independence for older adults to go out in their neighborhood to socialize (Figure 24-1).

FIGURE 24-1 Mobile devices such as scooters provide independence for older adults with limited mobility.

Nurses can be very helpful in talking with older adults to learn their goals for health and what motivates them. If a person dislikes group activity, it may not be effective to encourage him or her to take exercise or nutrition classes. Suggesting an exercise DVD that can be used at home or reading about nutrition may be more helpful. It is important not to underestimate older adults' abilities; many older adults continue to actively participate in competitive sports. Even chronic illnesses do not need to prevent health-promotion activities. Older adults should be encouraged to continue with self-care activities rather than to relinquish them to caregivers. Because some memory impairment may be present in cognitively healthy older adults, memory aids and familiar environments should be encouraged so that they keep their minds active, continue learning, and maintain their self-confidence.

A variety of activities promote health and prevent frailty. These include maintaining healthy weight and diet; staying active; practicing fall prevention; maintaining relationships; and keeping

regular medical appointments. Additionally, the CDC (2011a) recommends clinical preventive services for older adults that include immunizations (influenza and pneumococcal) and screenings for early detection of breast cancer, colorectal cancer, diabetes, lipid disorders, and osteoporosis; and smoking cessation counseling for those who smoke. Under the Affordable Care Act of 2010, many of these services are provided at no cost to older adults who have Medicare. SilverSneakers is a popular exercise program that is available at no cost to many older adults through their Medicare or private insurance plan (Healthways, 2014). There are also many different on-line and mobile applications that aid in monitoring exercise and may be fun for older adults to use. Helping an older adult to understand the importance of learning or maintaining healthy behaviors is an essential nursing role.

Health-maintenance behaviors include exercise, good nutrition, sexual safety, and appropriate sleep-rest patterns. Health-maintenance practices also include regular health care checkups, which will provide early detection and management of disease. Although these behaviors are important for all older adults, the perception of these activities and the ability to practice good health behaviors differ by cultural group. It is essential that nurses are culturally competent and understand the cultural values that guide behavior. In so doing, the nurse will be most effective in helping the older adult form a positive health perception and practice good health behaviors (Box 24-5 Innovative Practice).

Box 24-5

Innovative Practice

Geriatric Assessment

The health care system, with its emphasis on acute care, busy office schedules, and fragmented delivery systems, often frustrates older people and their families. The very old or frail person's health problems are often overlooked, ignored, or only partially treated.

Many communities have a health care service that uses a team approach to meet the special needs of older adults. This service is known as geriatric assessment.

Goals of Geriatric Assessment

- Maintain health and health maintenance practices.
- Promote disease prevention through routine immunizations and health screenings.
- Implement fall prevention strategies to decrease the incidence of falls and fall-related injuries.
- Minimize hospitalizations.
- Establish complete diagnoses that are often missed or overlooked, including hearing impairment, vision deficits, early dementia, depression, and poor nutrition.
- Decrease overprescription and misuse of medications, including prescription medications, over-the-counter medications, vitamins/minerals/supplements, and herbal remedies.

Geriatric assessment uses an interdisciplinary team consisting of a geriatric nurse practitioner, a physical therapist, and a social worker. Each member of the team evaluates the person from a health care, functional, cognitive, or psychosocial perspective. Additional members of the team might include a geriatric psychiatrist, geriatrician, nutritionist, pharmacist, dentist, or podiatrist. The program team evaluates the home environment, risk of falls, incontinence, vision and hearing impairments, memory loss, depression and anxiety, functional decline, physical deconditioning, caregiver stress, economic resources, advance directives, and quality-of-life issues. The team is coordinated by the geriatric nurse

practitioner.

Geriatric assessment is not meant for all older people. The people who benefit are those who are frail. An older person who might benefit from geriatric assessment is one who:

- Is older than 80 years
- Has a history of frequent falls
- Is losing weight
- Is depressed
- Has mild memory loss
- Has been hospitalized three times in 2 months
- Takes more than five medications regularly and frequently gets them confused
- Has no close family or other support persons in the community
- Is in need of health teaching

Geriatric assessment usually identifies the strengths and weaknesses of the older adult and evaluates that person's situation, including family and other social support. Following the assessment, the geriatric nurse practitioner begins developing a care plan to incorporate usable strengths and assist with weaknesses.

The primary care physician, family physician, internist, geriatrician, or geriatric nurse practitioner is a key link between the geriatric assessment team and the individual, primarily because this provider carries out the team's recommendation and monitors the person's progress. In most cases the nurse practitioner coordinates between the team and the person's primary physician and family.

Geriatric assessment clinics are available in many larger cities. As the US health care system changes from its costly system of treating

acute health problems with frequent office and hospital visits to a more cost-controlled, coordinated, comprehensive health management system, geriatric assessment will play a key role in identifying individual strengths, correcting problems, and maintaining the health and quality of life of older citizens.

Nutritional-Metabolic Pattern

Proper nutrition helps prevent cancer, obesity, and gastrointestinal disorders and provides older adults with the energy required to function in all **activities of daily living**. One can measure good nutrition by determining whether the individual is meeting the recommended daily allowance (RDA) for caloric intake. The US Department of Agriculture (2010) established the RDA of 2000 to 2800 calories for men aged 51 years or older: 2000 to 2200 calories for sedentary men, 2200 to 2400 calories for moderately active men, and 2400 to 2800 calories for active men. The range for women aged 51 years or older is 1600 to 2200 calories—1600 calories for sedentary women, 1800 calories for moderately active women, and 2000 to 2200 calories for active women.

Poor nutrition in older adults not only affects their overall health but also contributes to higher health care costs. Specific nutritional risk factors for US older adults include solitary living, being of a particular race/ethnicity, low income, social isolation, and low social support (Tyler et al., 2014). The National Resource Center on Nutrition, Physical Activity & Aging (2012) stated that between 35% and 50% of older residents living in long-term care facilities are malnourished and approximately 65% of older adults in hospitals may be malnourished. These data underscore the problems of maintaining good nutrition. For independent seniors, the barriers that may interfere with the ability to obtain adequate and nutritional food include limited transportation, income, and social support resources.

Problems with access to food are compounded by the effect of normal changes of aging. Declines in gastrointestinal organ function can lead to changes in digestive metabolism and the absorption and elimination of nutrients. A deterioration of the smell, vision, and taste

senses and the high frequency of dental and swallowing problems make maintaining adequate daily nutrition even more difficult. Additionally, side effects of required medications may affect appetite. Cultural food preferences and lifelong eating habits, such as diets high in fat and cholesterol, are other obstacles to maintaining optimal nutrition.

Because of physiological and metabolic changes associated with aging, nutritional problems are more difficult to quantify and evaluate in older adults (Mueller, 2015). A nutritional assessment for an older adult entails a comprehensive approach that includes a health history, physical examination, laboratory data, dietary data, and measurement of functional status. Initial **nutritional screening**, however, is more straightforward. Nutritional screening evaluates the risk of malnutrition and may identify the need for a more formal nutrition assessment. There are a variety of tools, such as the Mini Nutritional Assessment (MNA), that can be used for nutritional screening in older adults. The MNA contains an initial set of questions that if scored below 11 indicates risk of malnutrition and requires the completion of additional questions to confirm the likelihood of malnutrition (Mueller, 2015). The MNA and other screening tools can identify the risk of malnutrition, but a formal nutritional assessment is needed to establish a diagnosis of malnutrition and appropriate interventions.

The living environment further affects nutritional status. Community-dwelling seniors are at high risk of nutritional disorders because access to food may be limited. Older adults in long-term care facilities do not have a problem with availability of food, but the meals may contain excessive fat, cholesterol, or salt, and may lack sufficient fiber. Additionally, fresh fruit and vegetables are less available. Institutional food may be unappealing, and institutions may not be able to adapt their meals to the cultural and religious preferences of their residents. Encouraging family members to bring in special foods that the resident enjoys is helpful. Nurses who work in institutional settings make an important difference for older adults by assessing the person's food preferences and any difficulties in eating, followed by careful planning of an appropriate menu, to

encourage healthy eating.

A pleasant setting with social interaction enhances the desire to eat. In one study an expert panel of nutrition practitioners concluded that the two most important enablers of healthy eating among older adults are accessibility and social support (Tyler et al., 2014). Many older adults want to age in their own home without having to relocate to a long-term care facility. Research suggests that nutritional supports play a critical role in older adults' ability to remain in their homes (Tyler et al., 2014). Food assistance from friends and family in the form of cooking or food sharing is an important facilitator of nutritional health and being able to age in place. One study focused on how social lives and community environmental supports and barriers affected older adults' nutritional health (Tyler et al., 2014). The researchers conducted 29 focus group discussions with 144 residents of one of the largest retirement communities in the United States. The findings revealed that the high social connectedness of residents was associated with both positive and negative influences. The high degree of social support in the retirement community positively influenced the nutritional health of the participants. Social gatherings, however, also appeared to encourage residents to eat more than they would by themselves and to eat less nutritious foods. The findings also suggested that friends and neighbors provide an excellent point of entry for nutritional interventions such as information about food assistance strategies and other types of educational programs for health promotion.

Anorexia, or lack of appetite, can accompany disease. Medications, poor dentition, difficulty swallowing, or a lack of dentures can also cause older people to eat less than is optimal. Those in acute care hospitals or long-term care facilities may experience a lack of appetite as a result of illness. The hospital stay is a time during which good nutrition is most important to heal wounds and to restore energy; however, a lack of interest in or energy for eating during hospitalization places the older adult at a high risk of developing nutritional disorders.

Obesity is also a problem for older adults. Ogden and colleagues

(2012) reported that 39.7% of adults aged 60 years or older are obese, with older women having a greater incidence of obesity (42.3%) than older men (36.6%). Obesity is associated with several chronic health conditions, including hypertension, diabetes, and heart disease. It is important to recognize, however, that scientists have described a phenomenon called "the obesity paradox," in which obesity in older adults, unlike in younger individuals, does not appear to be clearly associated with a shorter life span. Some studies have suggested that the "ideal" protective weight might be higher in the older population (Pietrzykowska, 2016). There is still much debate about this, however, and because obesity is clearly linked to a lesser quality of life, it is important to discuss options for weight reduction. During weight loss, muscle is lost, as well as fat. This is an important consideration when one is planning a weight loss program for older adults because, as a result of normal aging and often deconditioning, they are likely to have less muscle mass and more fat than when they were younger. Studies have found, however, that a moderate weight loss of 5% to 10% results in significant health benefits and that even a weight loss of 3% in older adults significantly reduces inflammation, blood pressure, cholesterol levels, and blood glucose levels (Pietrzykowska, 2016). For nurses working with older adults who are trying to lose weight, it is important to recognize that these individuals may have struggled with trying to lose weight for years and may be very frustrated with their unsuccessful efforts to achieve an ideal weight. Factors such as living alone and not wanting to cook for one person, the expense and short shelf life of fresh fruits and vegetables, medications, fast food, lack of motivation, and difficulty exercising make losing weight difficult. Nurses can help empower older adults by identifying realistic strategies for them to attain and maintain a healthy weight.

Nurses assist older adults in maintaining the highest possible nutritional level by teaching them about the food needed to maintain optimal nutritional status and by providing information about resources to help purchase food. One important resource is the federal Supplemental Nutrition Assistance Program (SNAP), formerly known as the Food Stamps program. SNAP is available to those who meet

certain economic criteria, and can help older adults obtain nutritious food at participating markets without them depleting their limited budgets. When the economy declines, there is an increase in unemployment and poverty, and more people need help buying nutritious food. SNAP can provide needed help, but many people who are eligible for SNAP benefits, including 67% of struggling older adults, do not apply (Squires, 2014). Only three in five older adults who qualify for SNAP actually use it, which means that 5.2 million seniors are missing out on benefits of the program (National Council on Aging, n.d.). Some older adults are too embarrassed to apply, and others think it is too difficult to apply or do not even know the program exists. Yet for years they have paid taxes that help to support the program. The American Association of Retired Persons (AARP) has implemented initiatives to encourage more older adults to participate in SNAP. As a result of the AARP's work, in collaboration with other organizations, 20,000 new SNAP applications were submitted in 2013 (Squires, 2014).

In addition to SNAP, there are other federally supported nutrition assistance programs available to older adults, including the Commodity Supplemental Food Program, the Child and Adult Care Food Program, older adult nutrition program ("meals on wheels"), and the Emergency Food Assistance Program. The Older Adults Nutrition Services Program, which includes meals on wheels, provides nutritional services specifically to older adults. Detailed information about this program, as well as other important nutritional information related to older adults, is given in Chapter 11.

Elimination Pattern

Bowel and bladder functions in the older adult are altered by normal changes of aging. The bladder retains its tonus, but its capacity decreases. Gastrointestinal motility decreases as people age. In addition to some of the normal changes of aging, diet plays a significant role in problems with intestinal motility and constipation. Decreased intake of fluids and fiber contribute in large part to constipation. Many medications taken by older adults also cause

elimination concerns. Lack of physical activity and changes in the environment that decrease privacy also contribute to elimination problems. Many older adults may believe elimination problems are a necessary part of aging and may be embarrassed to mention their concerns to health care providers. It is important to reassure them that through diet and exercise they can gain control of most elimination problems.

Constipation is often a major problem for older adults and has far-reaching effects on their quality of life. There are several bowel elimination problems that are described by people as constipation: hard stools, infrequent stools, the need for excessive straining, and a feeling of incomplete bowel evacuation often associated with abdominal cramping or feeling bloated. Although inadequate diet and inactivity are common causes of constipation, it is important to consider whether constipation is related to metabolic disease such as hypothyroidism, neurological disease such as Parkinson disease, psychological illness such as depression, or medications. Nurses can assess the cause of constipation and develop an appropriate plan of care. Encouraging older adults to exercise and increase their fluid intake helps reduce the incidence of constipation. Integrating more fiber into the diet and eating prunes each day can also be very effective for preventing constipation.

Urinary incontinence affects approximately 50% of older adults who live at home or in long-term care facilities (Gorina et al., 2014). Incontinence is classified as either acute (transient) or chronic (established) (Touhy & Jett, 2012). Acute incontinence has a sudden onset, has been present for less than 6 months, and is usually secondary to a treatable condition. Chronic incontinence has either a sudden or a gradual onset and is categorized into four major types: **stress incontinence**, which is the most common and occurs during exercise, laughing, coughing, or sneezing; **urge incontinence**, or the inability to delay voiding after the bladder is full; urge, mixed, or stress urinary incontinence with high postvoid residual incontinence, which occurs when the bladder does not empty completely and becomes overdistended, which may be caused by an obstruction in the

urinary elimination tract, such as that caused by an enlarged prostate gland; and functional incontinence, which is associated with environmental barriers, physical limitations, or cognitive impairment where the person is unable to reach the toilet.

Incontinence results in threats to both psychological and physical health, including depression, urinary tract infections, skin breakdown, and falls. Nurses can help older adults to understand incontinence as a manageable problem. Implementing appropriate management is important for the older adult's continued good health and self-esteem. Pelvic floor or Kegel exercises can be taught to strengthen the musculature of the urinary system (Mayo Clinic, 2015a,b). Pilates exercises have also been demonstrated to be effective in treating incontinence (Crawford, 2013). Management programs may include scheduling regular times to void, improving access to toileting facilities, management of diet and fluids, and the use of disposable absorbent undergarments. Voiding schedules are most effective when the person selects specific times during the day for urination. Eliminating dietary caffeine helps people with urge incontinence and increasing fiber in the diet helps those whose incontinence is related to constipation.

Activity-Exercise Pattern

It is estimated that only 20% of American adults meet the aerobic and muscle-strengthening components of federal physical activity recommendations, and studies show that older adults get even less activity (CDC, 2013b). Men are more likely to meet the guidelines than women, and white older adults are more likely to meet them than black or Hispanic older adults. The benefits of regular exercise in promoting health and preventing disease are widely accepted. The overwhelming evidence of the positive effects of exercise has led the USDHHS to develop within its *Healthy People 2020* program national objectives for increasing the percentage of adults who exercise regularly. Regular physical activity helps and may even prevent many chronic health problems associated with aging, including hypertension, obesity, diabetes, and depression. Regular physical

activity can increase both the years of life and the quality of those years. Strength training can improve balance and reduce the risk of falls, strengthen bones, and reduce blood glucose levels. Normal changes of aging, pathological conditions, and environmental deterrents do not need to prevent the older adult from exercising (Figure 24-2).

FIGURE 24-2 Normal changes of aging and environmental deterrents do not prevent older adults from exercising.

The CDC (2011b) recommends a combination of aerobic exercise and muscle-strengthening activities every week. Aerobic exercise may range from moderate intensity to vigorous intensity depending on the older person's level of fitness, and muscle-strengthening activities can include exercises that work all major muscle groups. Teaching the many benefits of exercise is the first lesson in motivating older adults to engage. With respect to the role that culture plays on the value of exercise, individual counseling is needed to identify exercises that can be enjoyed and continued (Figure 24-3). The nurse or physical therapist assists in designing an appropriate exercise program that will help to maintain strength, flexibility, and balance. Walking, which

can be done in both community settings and health care facilities, is a popular form of exercise among older adults.

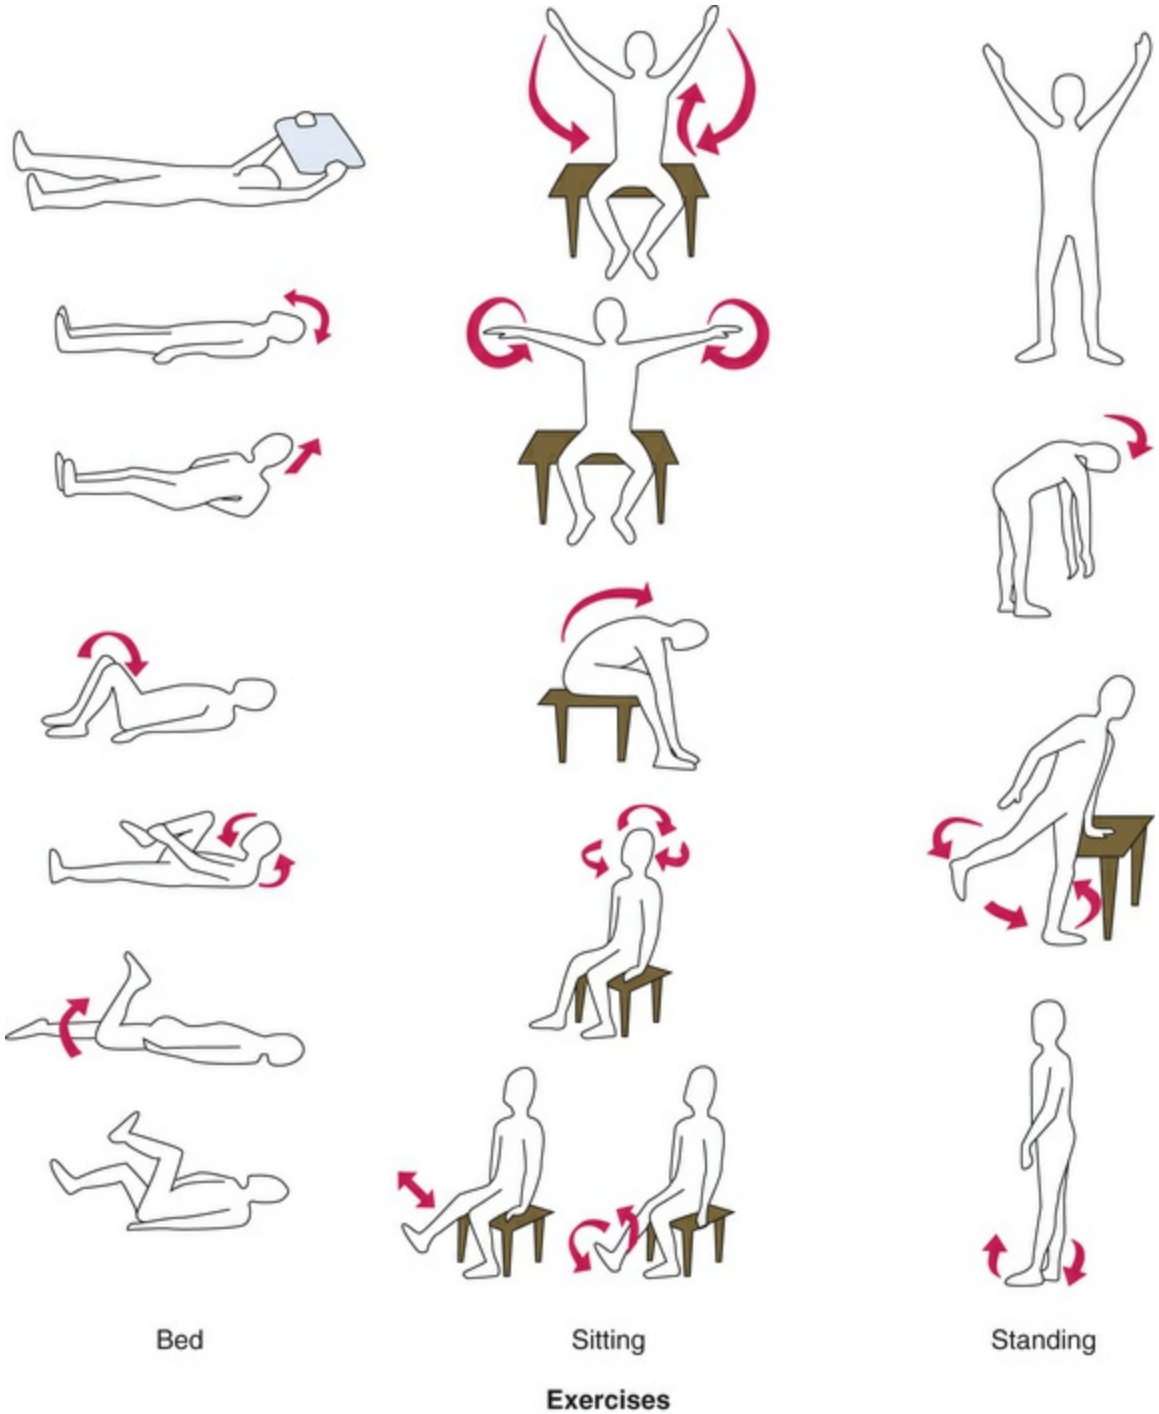

FIGURE 24-3 Bed-lying, sitting, and standing exercises.
(Redrawn from Ebersole, P., & Hess, P. [1998]. *Toward healthy aging: Human*

need and nursing response [3rd ed.]. St. Louis: Mosby.)

Other popular activities for older adults include swimming, weight-bearing exercises, and aquatic exercises. Weight-bearing and muscle-building exercises help to maintain functional mobility, promote independence, and prevent falls. Weight-bearing exercises are shown to be highly effective in reducing bone wasting associated with osteoporosis. Regular exercise promotes maintenance of bone mineral density in older adults. People with conditions such as spinal stenosis and arthritis often find that they can exercise in a swimming pool without pain, so this is an important way for them to maintain an exercise plan and increase their functional ability. Box 24-6 lists many benefits that can be derived from participation in an exercise program.

Box 24-6

Benefits of Exercise in the Older Adult

- Better sleep
- Reduced constipation
- Lower cholesterol level
- Lower blood pressure
- Better digestion
- Weight loss
- Socializing opportunities
- Greater sense of well-being

Before beginning any exercise program, an older person who has not been exercising should consult a physician or nurse practitioner. After the program begins, activity levels can be increased gradually.

Adherence to an exercise program is a major problem for all populations. The best strategies to encourage continued exercise among older adults are to communicate the importance of exercise in maintaining quality of life and to help them choose an exercise that they enjoy and is easily accessible. Exercising with a family member or friend is also helpful in motivating older adults to exercise.

Sleep-Rest Pattern

Inability to sleep is a frequent concern of older adults. Neikrug and Ancoli-Israel (2010) reported that approximately 50% of older adults state that they have difficulty sleeping. Sleep difficulties may include sleep apnea, the inability to fall asleep, the inability to stay asleep, the inability to fall back to sleep when awakening in the night, or the feeling of not being refreshed when awakening in the morning. Sleep-disordered breathing, or sleep apnea, may affect 20% to 40% of older adults and is associated with increased risk of stroke and death (Redline et al., 2010). **Restless legs syndrome**, characterized by unpleasant throbbing, pulling, or creeping sensations in the legs and an almost uncontrollable urge to move the legs, is a neurological disorder that affects many older adults (National Institute of Neurological Disorders and Stroke, 2015). As the sensations are worse when the person is lying down and trying to sleep, the disorder can seriously limit sleep quality. Older adults are more likely to report excessive daytime sleepiness, which means that they find it difficult to remain awake or alert at appropriate times during the day (Chervin, 2015). The high prevalence of sleep disorders in older adults indicates that it is an important area for health care providers to address.

The benefits of a good night's sleep are numerous. Quality sleep results in overall increases in energy, motivation to continue a high quality of life, and improved immune function. Because of the problem with sleep, *Healthy People 2020* added a new topic related to sleep health with the goal to "increase public knowledge of how adequate sleep and treatment of sleep disorders improve health, productivity, wellness, quality of life, and safety." Nurses assist older adults in achieving a good night's sleep through assessment that

might reveal possible causes of sleep disturbances. The Pittsburgh Sleep Quality Index is a subjective tool that is helpful in assessing the quality and patterns of sleep in older adults (Smyth, 2012). The tool measures seven areas: subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medication, and daytime dysfunction. Teaching older adults about normal changes reassures them that their sleep patterns have changed but are not necessarily harmful. Having this information may decrease anxiety. Identifying normal bedtime rituals, such as drinking a glass of milk, taking a relaxing bath, reading, or meditating, and ensuring that the person is able to continue these practices may help to establish normal sleep routines. Increasing physical activity during the day also helps them fall asleep more readily at night. Taking pain medication or using alternative pain-relief methods before going to bed can help those who suffer from painful conditions obtain better rest at night.

Residents of nursing facilities or people in acute care facilities may have difficulty adjusting to the environment at night. Adjustments in noise and lighting help these individuals sleep better. Emotional disorders frequently interfering with sleep can be identified, and therapy and medication can be administered during the day to help people experiencing these problems sleep peacefully at night. Although a nap may be beneficial, it is important to ensure that daytime napping is not interfering with nighttime sleep (Box 24-7: Innovative Practice).

Box 24-7

Innovative Practice

Measures to Promote Sleep

Sleep problems can be caused by many things, including stress; medications; medical conditions such as angina, asthma, anxiety, or depression; poor sleeping habits; and sleep disorders. The following are some suggestions to improve sleep in older adults.

Do

- Plan a regular bedtime and wake-up schedule.
- Participate in exercise, hobbies, and other activities during the day.
- Develop specific bedtime rituals, such as reading, meditating, drinking a glass of milk, or taking a warm bath. These tell the body it is almost time for sleep.
- Ensure a comfortable and quiet sleep environment, which is dark except for night safety lights.
- Sleep on a comfortably firm mattress with comfortable pillows and bedclothes.
- Use the bed only for sleep and sexual activities.
- Check with a physician about prescription and over-the-counter medications that may interfere with sleep.

Avoid

- Long daytime naps that may interfere with nighttime sleep
- Exercise or vigorous activity immediately before bedtime
- Caffeine after mid-morning
- Drinking alcohol before going to bed
- Sleep medications
- Tobacco products
- Driving when tired or sleepy

When Sleep Problems Persist

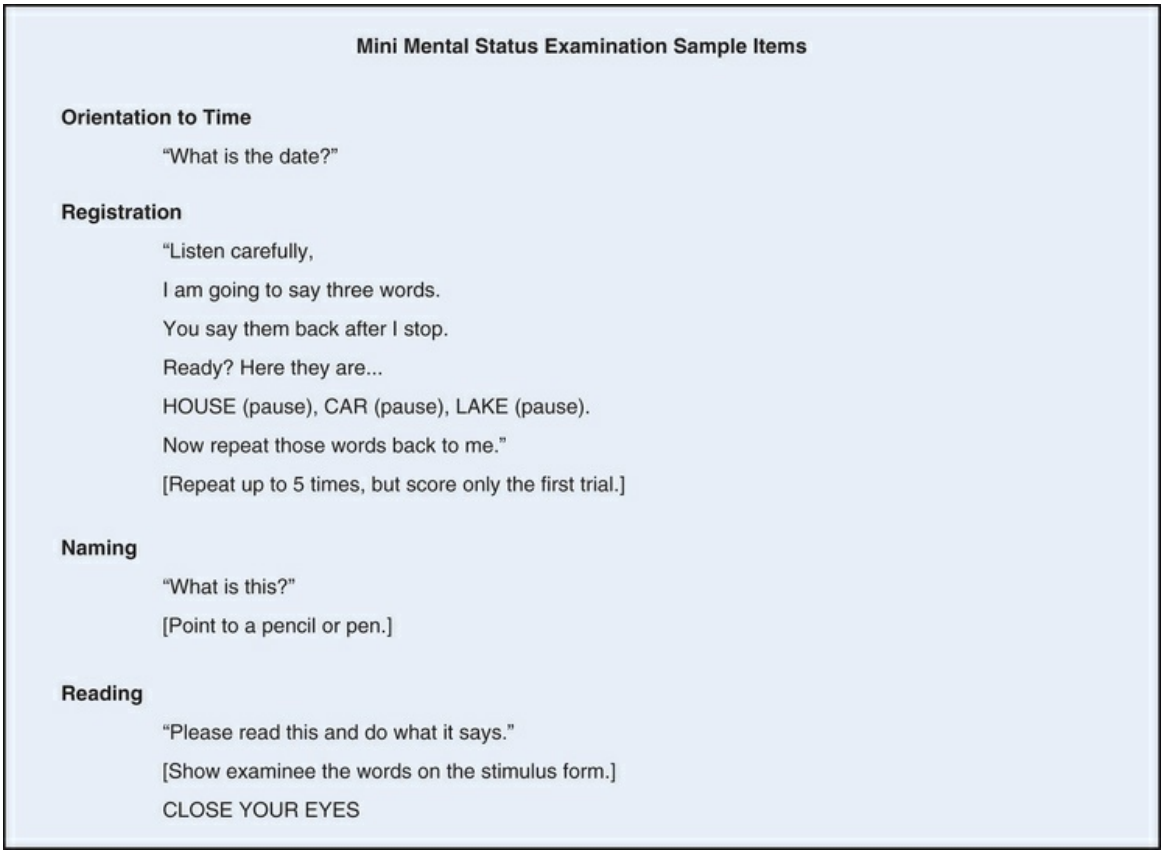
- Keep a sleep log, recording times and duration of sleep throughout the 24-hour period for at least 1 week.
- Ask sleep companion about sleep habits, such as snoring or restlessness.
- See health care provider.

Sleep medications may be helpful for short-term use; however, the American Geriatrics Society (2015) Beers criteria recommend avoidance of long-term use of benzodiazepines, barbiturates, and chloral hydrate for treatment of insomnia in older adults because of older adults' increased sensitivity to these drugs and increased risk of dependency, and the decreased metabolism of long-term agents, resulting in an increased risk of cognitive impairment, falls, and overdose.

Cognitive-Perceptual Pattern

Cognition

Thinking processes **(cognition)** in old age have been the subject of intensive study in the past few decades. Brain weight decreases with aging, and a shift occurs in the proportion of gray matter to white matter. The ways in which these changes are manifested in individuals differ because of culture, heredity, lifestyle, environmental exposures, and many other factors. Obesity affects cognition, which includes the processing of information, memory, comprehension, problem-solving, and decisions. It is important to think about how even subtle changes in cognition may affect older adults in their day-to-day activities. For example, older adults are often targeted by scams that ask them to send money or personally identifiable information to callers who appeal to their sense of fear or the promise of a reward.



There is a common belief that most older adults will eventually develop dementia; however, cognitive problems are not a normal change of aging, and many individuals live well into old age without ever experiencing dementia. It is important to be cautious in assessing older people who present with confusion, because confusion is not always indicative of dementia, but can be the result of many treatable health problems, including electrolyte imbalances, diabetic ketoacidosis, and hypoxia. **Mild cognitive impairment** is a pathological collection of symptoms that results in memory loss, language difficulties, and impairments in judgment and reasoning. A review of **instrumental activities of daily living** will help identify changes in higher executive functions, such as paying bills, taking medications as ordered, using the phone, and driving safely.

A condition that is receiving increased attention in older adults is **postoperative cognitive dysfunction** (POCD). POCD is a temporary deterioration in cognition that is associated with surgery and anesthesia (Sorrell, 2014). As the population of older adults has increased dramatically in recent years, surgery is more common at advanced ages. Individuals with POCD experience postoperative cognitive changes that may include anxiety, blurred vision, inability to sleep, hallucinations, and depression. POCD is not the same as **delirium**, which is a short-term change in cognition that may develop in the immediate postoperative period. Cognitive changes in POCD are more subtle and extend over a longer period—sometimes for months after discharge from the hospital. These changes can be very distressing to the older adult and the older adult's family. POCD is thought to be related to the type or amount of anesthesia administered during surgery, but more research needs to be done to establish the cause of POCD and how to prevent it. It is important for nurses in all health care contexts to be aware of the possibility of POCD in older adults and to identify ways in which they can intervene. Because there is no specific treatment for POCD, nurses need to anticipate the needs of both older adults and their family. Educating the older adult and the family about POCD and emphasizing that it is usually temporary helps to decrease anxiety.

Dementia is not accepted as a normal change of aging. Dementia is an umbrella term for a group of cognitive disorders that affect memory and lead to difficulty in areas of language, motor activity, object recognition, and ability to plan and organize. The high incidence of dementia and Alzheimer disease in older adults prompted the USDHHS to add *dementia, including Alzheimer disease*, as a new topic in *Healthy People 2020* with a goal to decrease morbidity and costs associated with dementia and maintain or enhance the quality of life for people with these cognitive disorders.

Dementias include **Alzheimer disease**, the most common dementia, as well as Parkinson-related dementia, Huntington disease, Creutzfeldt-Jakob disease, Pick disease, and Lewy body dementia. The Alzheimer's Association estimates that approximately 5.1 million Americans older than 65 years have Alzheimer disease and approximately 81% of individuals with Alzheimer disease are 75 years or older (Alzheimer's Association, 2015).

The symptoms of dementia include forgetfulness, inattentiveness, disorganized thinking, altered levels of consciousness, perceptual disturbances, sleep-wake disorders, psychomotor disturbances, and disorientation. Assessment for dementia can be made part of the routine assessment of older adults, especially if any of these symptoms arise. One tool that has been used successfully to screen older adults for cognitive impairments is the **Mini-Mental State Examination** (MMSE) (Folstein et al., 1975; Yellowlees, 2015) (Figure 24-4).

Mini Mental Status Examination Sample Items

Orientation to Time

"What is the date?"

Registration

"Listen carefully,
I am going to say three words.
You say them back after I stop.
Ready? Here they are...
HOUSE (pause), CAR (pause), LAKE (pause).
Now repeat those words back to me."
[Repeat up to 5 times, but score only the first trial.]

Naming

"What is this?"
[Point to a pencil or pen.]

Reading

"Please read this and do what it says."

The Mini-Mental State Examination can be purchased from Psychological Assessment Resources, Inc., by calling 800-331-8378 or 813-968-3003.)

The MMSE was developed to assess the baseline mental status of older adults and to evaluate change or decline in mental functioning. The instrument is based on a 30-point scale that measures the level of awareness and orientation, appearance and behavior, speech and communication, mood and affect, disturbances in thinking, problems with perception, and abstract thinking and judgment. The higher the older adult scores on the examination, the more intact the mental status is presumed to be. When the result of the examination is 23 or lower, the individual is determined to have a problem with cognition. It is important to note that this instrument has been criticized for its

cultural insensitivity, and it is difficult to use among individuals who speak languages other than English and among those with visual impairment and low literacy.

The MMSE is relatively easy to perform after a little practice and has been used for initial and subsequent evaluation of older adults in a variety of settings. The most effective way to perform the assessment is to make the person comfortable and establish a rapport. Eliminating extraneous noise and promoting attention and concentration will allow individuals to answer questions to the best of their ability. After the examination the score can be computed and used as a basis for care planning and further evaluation.

There is no cure for Alzheimer disease (CDC, 2015a). Treatment of Alzheimer disease includes the use of medications for memory loss, including cholinesterase inhibitors and memantine, treatments for behavioral changes associated with Alzheimer disease, and treatment for sleep changes. Medications to treat Alzheimer disease are known as cholinesterase inhibitors. These medications are most effective during the early stages of the disease and act by increasing the levels of acetylcholine in the brain to prevent further loss of cognition and improve cognitive status.

Nonpharmacological techniques for managing the problems associated with dementia include developing and keeping routines; working in a calm, gentle, and unhurried manner; encouraging self-care activity; and reducing sensory overload. Interventions to keep the older adult safe include curtailing wandering behavior and preventing falls and other injury.

Sensory Factors

Older adults experience age-related changes in vision, hearing, taste, smell, and touch sensation. Because of the normal changes and potential pathological changes associated with the senses, older adults of all cultural backgrounds and in all settings benefit from routine assessment and appropriate nursing interventions. Safety, particularly while driving, is a concern for older adults and society. Sensory changes affect a person's ability to drive safely. Nurses can encourage

older adults to take senior driving classes to learn how to become safer drivers as these changes occur.

A variety of structural changes cause visual acuity to decrease, color discrimination to become less acute, pupil size and constriction ability to decrease, and peripheral vision to diminish. **Presbyopia** is a loss of accommodation that occurs as people age and results in the inability to maintain focus on objects close to the eye. The lens of the eye thickens and becomes yellow and predisposes the older adult to cataracts. The older adult is also at increased risk of **glaucoma**, a group of eye disorders characterized by increased intraocular pressure. Because of the normal changes in the aging eye and the high risk of disease, a baseline eye assessment should be done to identify age-related changes and any disease processes. Follow-up eye appointments should be scheduled annually.

The nurse routinely assesses the older adult for the accumulation of cerumen (earwax) to ensure optimal hearing (see the case study and care plan at the end of this chapter). Hearing deficits are common in old age, resulting from inner ear **atrophy** or **sclerosis** of the tympanic membrane. The inner ear also undergoes a number of changes, including those that are cell degenerative and nerve related. **Presbycusis** is a progressive sensorineural hearing loss associated with aging, and results in difficulty filtering background noise and understanding higher-pitched voices. Sound threshold changes, with an associated difficulty in understanding what others are saying. Similarly to the changes of the eye, changes in hearing and the increased risk of pathological conditions indicate that older adults should have ear and hearing screening. Hearing loss occurs in approximately one in three persons aged between 65 and 74 years and in almost half of those older than 74 years (National Institute on Deafness and Other Communication Disorders, 2015). Loss of hearing can result in decreased quality of life, as it may lead to miscommunication, loss of self-esteem, depression, falls, safety risks, and cognitive decline. Hearing aids assist those with hearing loss to communicate more effectively.

Taste changes with aging because of a loss of taste buds. The flavors

of sweet, sour, salty, and bitter become blurred with this loss. The sensations brought about by touch may also diminish with the decrease in sensory nerve endings, especially in the presence of debilitating diseases such as diabetes, stroke, or Parkinson disease. The ability to smell and the acuity of the olfactory nerve also decrease with age. Because of the loss of smell and taste sensations, older adults have the tendency to increase the amounts of salt and sugar in their food, possibly negatively affecting chronic health conditions. Teaching older adults about safe cooking and the use of alternative seasonings in food may be helpful in helping them adjust to these sensory changes. Additionally, the sense of smell is impaired, which may result in the inability to sense common warning signals such as smoke or rotten food. It is helpful to teach older adults to check the dates on their food packages frequently and to be attentive when cooking and preparing meals so as to ensure safety.

The decline in taste and smell sensations, combined with problems of obtaining adequate nutrition, makes dental care of vital importance to this population. Lack of fluoridated water and preventive dentistry during the developmental years may have led to tooth and periodontal problems in the older population. Periodontitis, or gum disease leading to tooth loss, is a common contributor to decreased taste sensation and poor nutrition. *Healthy People 2020* established oral health objective OH-4-2 to reduce the proportion of older adults aged 65 to 74 years who have lost all their natural teeth and oral health objective OH-5 to reduce the proportion of adults aged 45 to 74 years with moderate or severe periodontitis (USDHHS, 2012a). The inability to chew and swallow food in a comfortable manner works synergistically with decreased smell and taste sensations and other problems that inhibit proper nutrition. The American Dental Association recommends that adults be seen for oral hygiene checks and counseling at least twice a year. During the initial evaluation, follow-up visits are scheduled to ensure that teeth and gums remain in good condition and that appropriate dental care devices are being used.

The skin of the older adult changes, becoming thinner, less elastic,

wrinkled, and more fragile. Although sweating decreases and injuries take longer to heal, the skin remains capable of sensing and performing its protective role. Chronic disease, however, can place an individual at risk of decreased sensation throughout the body. Cerebrovascular accidents (strokes) and neuropathies resulting from diabetes are two examples of diseases that disrupt the ability to feel pain and pressure through the skin. This lack of sensation can threaten safety. Older adults benefit from information about safety when cooking on a hot stove and the appropriate temperature for bathing and showering to prevent burns.

Nurses should perform frequent skin assessments to detect alterations in skin integrity at an early stage and implement appropriate interventions. The potential for skin impairment is common for those who have sensory impairment from physical disease or dementia. A pressure sore **(decubitus ulcer)** is a localized area of tissue necrosis that develops when soft tissue is compressed between two bony prominences or between a bony prominence and an external surface for a prolonged period. In addition to prolonged pressure on the skin, friction, moisture, shearing, and inadequate nutrition place the older adult at risk of developing a decubitus ulcer, which is difficult to treat. Preventing the ulcer is the best method for maintaining intact skin. People at risk of decubitus ulcers should change their position at least every 2 hours to redistribute pressure appropriately throughout all areas of the skin. Elevating the lower extremities and maintaining proper body alignment are imperative to prevent decubitus ulcers. Specialty beds are readily available in most care settings to decrease pressure and assist in positioning individuals who are at risk. Positioning pillows and other orthopedic devices provide ways to help maintain the proper support of body parts and body alignment. Proper nutrition, including adequate amounts of zinc and vitamins C and E, will help prevent this skin problem.

Self-Perception–Self-Concept Pattern

The variability of self-concept in the older adult is similar to the variability that is seen in the general population. As in all aspects of

health, culture, environment, family, lifestyle factors, and heredity combine to form self-concept. Self-concept includes an individual's attitudes, perception of abilities (cognitive, affective, or physical), body image, identity, general sense of worth, and general emotional pattern. Personality traits tend to remain constant throughout life.

Developmental Theories of Aging

Many believe that adults no longer grow emotionally or physically in their later years. In truth, although the rate of physical decline exceeds the rate of physical growth, no evidence was found that emotional growth declines in any way. One need only view the classic film *Driving Miss Daisy* to understand that older adults go through many developmental changes in the 30 to 40 years that often make up older adulthood. Erikson's (1982) theory of development asserts that older adults must pass through developmental stages as do infants, children, and younger adults. As in all stages of psychosocial development, unsuccessful passage through a stage can result in psychological illness, and successful passage through the stage promotes health (Erikson, 1982).

Ego integrity versus despair is the developmental stage of older adults (Erikson, 1982). The quality associated with successful passage of this stage is to achieve a balance between integrity and despair. "The process of bringing into balance feelings of integrity and despair involves a review of and a coming to terms with the life one has lived thus far" (Erikson et al., 1986). On the basis of the increasing life span, this stage of development was expanded into three additional stages: ego differentiation versus work role preoccupation, which involves achieving identity apart from work; body transcendence versus body preoccupation, which focuses on adjusting to normal aging changes; and ego transcendence versus ego preoccupation, which involves accepting death (Erikson, 1997).

Other developmental theorists have built upon Erikson's work. Some of these are included in Box 24-4: Theories of Aging. Levinson moved away from Erikson's focus on the role of tensions that emerge during successive stages and instead emphasized that major life

transitions are influenced by evolving physiological, psychological, and role-oriented life changes (Agronin, 2013). Vaillant also moved from an emphasis on "stages" to focus on developmental tasks of life. Vaillant theorized that generativity grows out of one's career. His studies suggested that successful generativity tripled the chances for a person to experience more joy than despair in their 70s (Agronin, 2013). Gilligan criticized Erikson, Levinson, and Vaillant for proposing theories that addressed only male development and focused her work primarily on the unique role of interpersonal connections in female development (Agronin, 2013).

Cohen is considered a founding father of geriatric psychiatry, bringing forth a modern conception of old age. He focused on the continued potential for growth that occurs not in spite of old age but because of it. His work demonstrated how the brain continually resculpts itself in response to experience and learning. Cohen also emphasized the role of creativity, which he believed persisted and even increased in old age. He proposed that older adults can develop a **social portfolio** to enhance moving through various phases. The social portfolio comprises individualized lists of vital activities that a person can engage in through an active review of lifelong personal assets. The social portfolio should include vital activities than a person can engage in even when faced with serious disability or loss (Agronin, 2013).

Nurses working in all settings are charged with helping older adults accomplish the task of balancing ego integrity and despair. Two successful methods of support for older adults at all cognitive levels are **reminiscence** and **life review**. An increasing number of researchers have found that there are substantial psychosocial health benefits for older adults who participate in reminiscence programs, with beneficial outcomes of enhanced mood, increased socialization, improved cognitive functioning, and enhanced well-being (Chippendale & Bear-Lehman, 2012; Smiraglia, 2015). There are many different types of reminiscence programs that are designed to engage participants in discussing their memories, sometimes with reflection prompts such as food or objects from the person's past. Life review is

a more formal therapy technique taking the person through his or her life in a structured and chronological order. Both of these therapeutic approaches can be done individually or in groups, orally or through writing.

Roles-Relationships Pattern

Although the general framework of self-perception remains constant throughout the life span, the source of an individual's self-perception often changes with older adulthood. The formation of the self that has focused on a person's role in the family changes when one's children become independent or a spouse dies. Roles such as daughter, son, sister, brother, wife, or husband may be lost because of death or illness. The loss of these roles can result in grieving, sadness, and potentially depression in the older adult. In contrast with the loss of these roles, however, new roles, such as grandparenting, evolve (Figure 24-5).

FIGURE 24-5 Loss of some roles can provide an opportunity for new roles. As family members grow up and move away, the older adult may decide to devote time to training dogs to be pet therapy dogs.

In the United States in 2012, 7 million grandparents (10%) lived

with at least one grandchild (US Census Bureau, 2014). The role of grandparent frequently brings great joy and happiness at a time when the older adult feels loss; however, grandparents who rear grandchildren encounter both emotional and physical stress. Their new role as grandparent-caregiver may lead to role confusion and increased health-related problems (Bundy-Fazioli et al., 2013). Researchers have also found, however, that these grandparents may show positive levels of physical activity and self-care, especially if they do not perceive the caretaking responsibility as highly stressful (Bundy-Fazioli et al., 2013). Thus it is important for nurses to explore with these individuals what activities may help to reduce stress. Coping strategies such as accepting responsibility, self-control, positive reappraisal, planned problem-solving, and distancing may be helpful. Support groups, counseling, and education to help them manage stress more effectively are other resources that should be explored. Encouraging and supporting older adults in their caregiving role is important to help them ease the stress and strain of changes that come with the caregiving experience.

With the average life span increasing, older adults can spend many more years in retirement than previous generations. There were approximately 54 million Social Security beneficiaries at the end of 2010 (Social Security Administration, 2012). Hooyman and Kiyak (2011) noted a variety of factors that were predictors of satisfaction with retirement. Those factors included good health and functional ability, adequate income, a suitable living environment, a strong social support system, and a positive outlook. An important factor was the autonomy of the retiree in choosing retirement and the preparation for the retirement while still working. For married retirees, having a good marital relationship and sharing similar interests with the spouse supported satisfaction with retirement. Having retirement activities that provide an opportunity to feel useful, to learn and grow, and to enjoy oneself are important. Many retirees enjoy sports and hobbies developed during their working years, whereas others become actively involved in volunteerism and other community and civic activities.

Volunteering can be an effective method for older adults to continue to feel engaged in the community as a productive, contributing member of society. Older adults who volunteer have an external incentive for getting dressed and going out of the house in the morning; they take a great amount of pride in their work. Filling a volunteer position provides a feeling of self-worth and helps to change negative feelings about retirement and other role changes. It also makes important contributions to society.

Federal and state funding has created a number of subsidized work programs for older adults. With the assistance of this funding through private agencies and local Area Agencies on Aging, older adults are given the opportunity to work for pay. Although the pay may not be comparable to that earned before retirement, the earnings can be a necessary supplement to Social Security benefits. These programs allow older adults to work in programs such as those involving children in day care centers and disabled and ill older adults at home and in administrative positions. Nurses can provide interested individuals with information about these programs.

Downsizing from the family home to a smaller residence, widowhood, retirement, and relocation can elicit profound feelings of loss. Older adults who remain engaged in a variety of activities and relationships are happier and healthier. Personality, and its expression over time, is considered a major determinant of how engaged or active a person will be late in life. Other variables such as culture, health, bereavement, and habit affect activity as well.

Health-promotion activities center on an understanding of the individual's usual behavior and any unexpected or unexplained deviation from that behavior. Nurses can help older adults identify the meaning of their lost roles and the results of those losses, and work through reactions to the losses. In more traumatic cases, support groups, such as bereavement groups, can be helpful. The nurse supports people going through role changes by eliciting reactions and facilitating communication about these reactions. Significant others, such as children, neighbors, and friends, can provide important support. The nurse is integral in helping older adults develop and

explore their new roles in their older years.

Sexuality-Reproductive Pattern

The World Health Organization defines sexual health as "a state of physical, emotional, mental and social well-being in relation to sexuality" (CDC, 2014b). In older adults, as in all adults, sexual health is characterized by an approach to sexual relationships that is positive and respectful. There has been much debate regarding the presence or absence of sexual desire among older adults, and many assume that older adults do not participate in sexual relationships. According to the AARP (2012), myths regarding sexual activity among older adults include the following: most older men have erectile dysfunction **(impotence)** and are unable to have sexual intercourse; after menopause, older women no longer have sexual desire; physical and psychological impediments in older adults make them unable to have sexual intercourse; an aging body is not sexy; and older people should not have sex. It is important to realize that sex does not belong solely to the young and that sexual contact correlates with enhanced health, positive relationships, and improved stress management (AARP, 2012).

Older adults who are not heterosexual may experience health disparities as a result of their gender orientation. There are an estimated 1.5 million older adults in the United States who self-identify as gay, lesbian, bisexual, or transgender (LGBT), and this number is expected to double by 2030 (Zelle & Arms, 2015). Although *Healthy People 2020* includes goals to achieve health equity and improve the health, safety, and well-being of LGBT individuals, research suggests that these individuals continue to face health disparities linked to social stigma, discrimination, and denial of their civil and human rights (Office of Disease Prevention and Health Promotion, 2014). The LBGT older adult population is more likely to delay seeking treatment for health problems and has a higher incidence of psychosocial problems. Nurses who use a nonjudgmental approach and open-ended questions related to marital status and sexual orientation can be very supportive in encouraging LGBT

individuals to openly express their concerns about their health and well-being.

The most accurate predictor of sexual interest in older adulthood is the enjoyment and frequency of sex at a younger age. No data were found to show that men or women lose interest in sexual activity as they age. Older adults also need to fulfill the human need for intimacy and love, and to touch and be touched. Touch is an overt expression of closeness and an integral part of sexuality. Although the need to express sexuality continues, older adults are susceptible to many chronic medical conditions, such as cardiac problems, arthritis, and normal aging changes that can make sexual intercourse difficult. In both sexes, reduced availability of sex hormones results in less rapid and less extreme vascular responses to sexual arousal. The lack of circulating hormones in both men and women results in changes in four areas of the sexual system: arousal, orgasm, postorgasm, and extragenital changes. In women the vagina becomes narrower, shorter, and thinner, and there is less natural lubrication. Men experience less intense and slower erections, increased difficulty regaining an erection, decreased force of ejaculation, and an extended refractory time. Medications and other measures to manage medical conditions can also hinder sexual response.

Nurses are in an ideal position to help older adults find ways to fulfill their sexual desires by compensating for normal aging changes and chronic medical conditions and medications. Knowledge is essential to the successful fulfillment of sexuality needs. After making a sexual assessment, nurses can intervene to prevent or correct problems, but they frequently choose not to consider sexuality when planning care. One of the reasons for this is that nurses may believe the societal myths about older adults' sexuality. With proper education and experience, they may be sufficiently confident to venture into this delicate area.

One way in which nurses can gain knowledge of the sexual needs of older adults is through a staff development program using role play to discuss and process feelings associated with an older person's limitations in fulfilling intimate and sexual relationships. The

expression of intimacy and sexuality among older adults results in a higher quality of life achieved through fulfilling a natural desire. In long-term care facilities, the need to address sexual needs of residents is great because of difficulties related to their chronic illnesses and because of a lack of resident privacy to engage in intimate and sexual relationships. Long-term care facilities can develop policies to assist residents in effectively fulfilling the need for intimacy and sexuality.

Many nurses believe that acquired immunodeficiency syndrome (AIDS) and other sexually transmitted infections (STIs) are not problems for older adults. However, the number of cases of human immunodeficiency virus (HIV) infection and AIDS in older adults continues to increase because greater numbers of older adults are becoming newly infected with HIV and an increasing proportion of those who have HIV are reaching their older years (CDC, 2017). Two areas that are so important for successful aging—cognition and social engagement—are of particular concern for those aging with HIV, as declines in both of these areas have been observed in this population (Vance, 2013). Approximately 50% of individuals with HIV experience cognitive problems, and as people age they may be at increased risk of developing cognitive changes. Social support and engagement often decline for many older adults and may be exacerbated by stigma and depression in older adults with HIV (Vance, 2013). It is important for nurses to suggest ways to promote social engagement, as this may help to improve both mood and cognitive functioning.

Older adults are just as susceptible to STI as younger adults. Yet one survey showed that only 5.1% of men older than 61 years had used a condom in recent sex (Esposito, 2016). There seems to be a lack of awareness in the older adult population about the risks of STIs in their sexual relationships. Esposito (2016) noted that if you go into an STI clinic and look at the brochures about AIDS or STIs, you do not see people with wrinkles and gray hair on the front of those brochures. It is important that older adults become more aware of risks in their sexual relationships and follow the safer sex guidelines recommended by the CDC (2013a).

Coping–Stress Tolerance Pattern

An individual's ability to cope with the common stresses of older adulthood is a key factor in maintaining self-concept. As people age, they tend to encounter many losses, such as the loss of a home, spouses, friends, siblings, and even children. They also experience declines in income and in health and physical functioning. The nurse who cares for the older adult can provide support during the coping process related to these losses. Trying to find the positive and developmental benefits of losses is preferable to continually thinking about a loss or bad event. Negative associations have been found between depressive symptoms and rumination, catastrophizing, and self-blame. After assessing the most appropriate way in which the individual desires to cope with a situation, the nurse may help create a suitable environment for coping.

The spirituality of older adults is also an important consideration in helping them cope with stressful situations. Spirituality is very individual and may be exercised privately or through a religious framework. However, the impact of spirituality on quality of life has been well documented among older adults and often has a strong relationship with older adults' ability to cope with the changes and losses of aging.

Depression

Among older adults, **depression** may mainly affect those with chronic illnesses and cognitive impairment and result in suffering, family disruption, and disability. Depression can worsen the outcomes of many illnesses and increase mortality. Aging-related and disease-related processes, including arteriosclerosis and endocrine and immune system changes, compromise the integrity of frontostriatal pathways, the amygdala, and the hippocampus, and increase vulnerability to depression. Heredity factors may also play a part. Psychosocial adversity—economic impoverishment, disability, isolation, relocation, caregiving, and bereavement—contributes to physiological changes, further increasing susceptibility to depression

or triggering depression in already vulnerable older individuals.

It is important to know that most older adults are *not* depressed. Estimates of major depression in community-dwelling older adults range from less than 1% to 5%, but these percentages rise to 13.5% in those who need home health care (CDC, 2015b). The National Institute of Mental Health (n.d.) noted that the risk of depression increases in older adults as they experience chronic illnesses and when their ability to function becomes impaired. The numerous losses experienced by older people may be partly to blame. Depression is also caused by physiological changes in the aging body. Although depression appears to affect older adults in much the same way that it affects younger individuals, certain patterns of symptoms and older adults' overall susceptibility are different from those of younger counterparts.

Nurses are integral in helping to diagnose and manage depression in older adults. Depression can be found in all care environments. Some common behaviors include sullen affect, lack of appetite and weight loss, sleep disorders, fatigue, decreased ability to think or concentrate, psychomotor agitation, decreased participation in daily living and social activities, social withdrawal, and suicidal ideation. Many instruments are available to assist nurses in assessing older adults for this commonly occurring disorder. The Geriatric Depression Scale (Yesavage et al., 1983) is available in several formats, with 30, 15, 5, or 1 question, and is easily administered. Positive results on the screening examinations require referral to social services for a diagnostic workup. After depression has been diagnosed, successful management may include implementation of antidepressant medications and psychosocial therapy.

Suicide

The suicide rate for older Americans is disproportionally high in the American population. The suicide rate for men is highest in those who are 75 years or older, 36.1 per 100,000. Non-Hispanic white men aged 85 years or older were the most likely to die by suicide, with a rate of 49.8 per 100,000 (National Institute of Mental Health, n.d.). Firearms, poison, overdose of pills, gas, and suffocation are common methods of

suicide used by older adults.

The reason for the high number of suicides in the older adult population continues to be explored. The elevated rate of depression helps the medical community understand the motive of many older adults. Many older adults have serious medical illnesses that provide an explanation for wanting to die. Risk factors for suicide include social isolation, alcohol and substance abuse, psychosis, bereavement, and serious medical illness. Many who committed suicide were found to have alcohol and/or pain-killing drugs in their bodies on autopsy.

The importance of different aspects of life also differs by culture. Some older adults may visit a health care provider with a somatic problem before the suicide attempt as, perhaps, a final call for help. Nurses working with older adults must be aware of the high rate of suicide in this age group and be alert for the risk factors. Older adults exhibiting signs of depression must be asked about possible suicidal thoughts. Suicide threats must be taken seriously and appropriate interventions implemented to keep the older adult safe.

The incidence of chronic illness that frequently accompanies old age raises a concern for ethical care. Many members of society believe that with the increased life span, individuals may be subjected to more suffering. A solution to ending the suffering of those with chronic illness has been **euthanasia**, or **physician-assisted suicide**. In many states, people are lobbying to legalize physician-assisted suicide. Nurses help society to understand the many benefits of older adulthood and celebrate the extended life span rather than deeming it wasteful. Nurses caring for chronically ill older adults have the added responsibility of determining who is at risk of wanting physician-assisted suicide and helping them to be as comfortable as possible and free of pain through the use of pharmacological and nonpharmacological interventions. Nurses are instrumental in ensuring that the older person experiences a pain-free death by advocating an appropriate pain-management program and working with other health care professionals toward this goal.

Values-Beliefs Pattern

Every person who nurses care for will have a different sense of spirituality, which will have an influence on the way the person chooses to live and the decisions made by the person about health care. Hodge and colleagues (2010) found that most older adults describe themselves as both spiritual and religious. The life of the spirit may help older adults to overcome the pain and suffering of chronic health and psychosocial problems encountered in their later years.

Nurses may find themselves in the providential but difficult position of attempting to promote the spiritual health of individuals. One reason for this perceived difficulty may be the nurse's discomfort with the person's belief system. Spirituality plays a significant role in meaning-making in relation to attitudes and beliefs about the world, self, and others.

There may be as many different spiritual values and beliefs as there are individuals. Differing spiritual values make helping older adults actualize their spirituality, and thus acquire a high quality of life, difficult for nurses. Because of the highly personal quality of spirituality, an unobtrusive and sensitive presence by the nurse is needed to allow the person in any setting to achieve spiritual health. Spiritual assessment tools are available to guide nurses with questions to better understand the person's spirituality. Open-ended questions such as “What is your perception of a higher being and spirituality?” encourage discussions about the person's innermost spirituality. The nurse can provide an environment that is supportive to the practice of the person's spirituality. Assisting older persons to actualize their spirituality can provide great comfort to the person and lead nurses to a deeper understanding of their own spirituality.

Environmental Processes

Physical Agents

Accidents

Healthy People 2020 identifies a goal of preventing unintentional injuries and violence, as well as reducing the consequences of these problems (USDHHS, 2015). One important focus for injury prevention in older adults is falls. Falls are a leading cause of morbidity and death among older adults. One in three older adults fall each year, and one in five falls result in a serious injury, such as a fracture or head injury (CDC, 2015c). Each year 2.5 million older adults are treated for fall injuries in emergency departments. More than 95% of hip fractures are caused by falls, and each year 250,000 older adults are hospitalized for a hip fracture. It is essential that nurses are knowledgeable about interventions for prevention (Box 24-8: Quality and Safety Scenario).

Box 24-8

Quality and Safety Scenario

Fall Prevention for Older Adults in the Community

Falls in community-dwelling older adults are a critical problem for nurses to address, as falls are the leading cause of injury in older adults. Between 30% and 40% of community-dwelling adults aged 65 years or older fall at least once per year. The US Preventive Services Task Force (USPSTF) makes and periodically updates recommendations about the effectiveness of specific clinical preventive services for older adults. The recommendations are based on the evidence of both the benefits and harms of the service. These recommendations are intended to provide helpful information for clinicians, but the USPSTF emphasizes that clinical decisions involve

more considerations than evidence alone and clinicians need to individualize decision-making for a specific client.

The USPSTF notes that various approaches to identify people at increased risk are helpful. There is no single evidence-based instrument that accurately identifies older adults at increased risk of falling. Clinicians need to assess risk on the basis of a variety of factors, such as a history of falls and impaired mobility and balance. Early intervention is important for people assessed to be at risk, as these interventions can prevent serious injury.

The USPSTF states that more research is needed for clinical validation of tools to identify older adults at risk of falling. It also recommends efficacy trials for interventions related to vision correction, medication withdrawal, protein supplementation, education or counseling, and home hazard modification.

Summary of Recommendations:

Exercise or physical therapy and vitamin D supplementation are recommended to prevent falls in community-dwelling adults aged 65 years or older who are at increased risk of falls.

The USPSTF does not recommend a routine in-depth multifactorial risk assessment in conjunction with comprehensive management of identified risks to prevent falls because the likelihood of benefit is small.

From US Preventive Services Task Force. (2012). Falls prevention in older adults: Counseling and preventive medication. http://www.uspreventiveservicestaskforce.org/Page/Document/RecommendationStatementFin prevention-in-older-adults-counseling-and-preventive-medication.

Some of the causes of falls in older adults are neuromuscular dysfunction, osteoporosis, stroke, and sensory impairment. Falls can result in decreased mobility, decreased ability to live independently, and increased risk of an early death. Although a fall in a younger individual may not be problematic, a fall in an older adult can have devastating consequences. Falls account for 40% of admissions to nursing homes each year. Even if the person is not injured in a fall, he

or she may develop a fear of falling, and therefore limit his or her activities and increase his or her risk of future falls.

Because of the higher risk of osteoporosis in the older population, a fall can result in a fracture. **Osteoporosis** is a disease of bone loss common to women aged 70 years or older and men aged 80 years or older. The disease develops six times more frequently in women than it does in men. The rapid decline in estrogen secretion at the onset of menopause signals the calcium in the bones to move into the bloodstream, which causes the bones to become weak and brittle. Because of this weakness, falls in older adults with osteoporosis frequently result in fractures, which place these individuals in a spiral of iatrogenic risk, beginning with weeks of decreased mobility and possibly resulting in decubitus ulcers, psychological trauma, pneumonia, and even death.

The risk factors for osteoporosis include a small, thin frame; white or Asian ancestry; family history of osteoporosis; excessive thyroid medication or high doses of cortisone-like drugs for treatment of asthma, arthritis, or cancer; a diet low in dairy products and other sources of calcium; physical inactivity; smoking cigarettes; and drinking alcohol. Osteoporosis is typically diagnosed after an older adult sustains a fracture. However, bone density testing is readily available to determine individuals at risk before a fracture occurs. Sufficient calcium intake remains vitally important and will continue to reduce the normal bone loss of aging. Health care providers frequently monitor calcium and vitamin D levels as a part of wellness care in older adults. Most women need 1000 mg daily before menopause and 1500 mg daily after menopause. Consuming this amount of calcium from today's average diet is difficult; therefore a calcium supplement is essential. Vitamin D is also essential for bone health. Although one can obtain adequate vitamin D by daily exposure to the sun, because of concerns about the amount of sun exposure necessary, 400 to 800 IU of vitamin D supplements is usually recommended in conjunction with calcium. For the prevention of osteoporosis and the optimal maintenance of both psychological and physical well-being in the older adult, regular physical activity is

necessary.

Governmental concern about falls among older adults has resulted in a *Healthy People 2020* objective to prevent an increase in the rate of fall-related deaths (USDHHS, 2012b). Less than half of older adults tell their physician about a fall, so it is important for nurses to inquire about falls. Because many factors contribute to falls, risk assessment is essential. If a fall has been sustained, the older adult is at increased risk of falling again, and fall-prevention strategies must be implemented. Several fall risk assessment tools have been developed, but more research is needed to validate their use in different settings. By identifying the risks of falls and assessing an older adult's vision, hearing, medication use, blood pressure, mobility, and other factors, nurses can predict and prevent many falls.

Table 24-2 lists frequent causes of accidents that occur in the home and nursing interventions to prevent them. Home care nurses are in an ideal position to prevent injuries. During the initial and subsequent assessments, the nurse can evaluate individuals' homes for common factors leading to fires, poisoning, and falls, such as frayed wires on electrical appliances that can produce sparks and start fires, improperly labeled cleaning products that can be accidentally ingested, loose rugs on the floor, absence of handrails on stairs or in bathrooms, and poor lighting that can cause falls. Appropriate health teaching incorporates the concept of accident prevention for all older adults living not only in the community but also in acute care facilities and long-term care facilities.

TABLE 24-2

Safety Risk Areas and Related Interventions

Area of Attention	Intervention
Stairways	Secure handrails Illuminate stairways with light switches at both top and bottom Eliminate clutter on all steps and stair landings Use nonskid treads on steps
Bedroom	Use nightlights Tack down carpet Discourage use of throw rugs Arrange furniture so that it will not obstruct clear pathways Secure extension cords and telephone wires and remove them from walking areas

	For smokers, never smoke in bed
Bathroom	Use handrails near tub and toilet Use nonskid mats in tub area and on floor Use a bath thermometer to measure hot water in tub Use nightlights
Kitchen	Wear nonflammable, lightweight clothing when cooking Place dishes and cooking utensils at reasonable heights Use stepstools with a handrail according to specifications and only when not alone Keep off wet floor and refrain from using slippery wax Never climb on chairs Keep emergency numbers near the telephone Ensure locks can be easily opened in times of emergency Cook at front of the stove rather than at the back Do not use electrical appliances with frayed cords
Living room	Use furniture that is easy to get in and out of Eliminate clutter on all floor areas Install fire detectors at appropriate places
Outdoors	Make sure stairs are free of breaks and cracks, and clear of snow and ice Use safe handrails Provide good lighting for stairs and walkways

The older adult's ability to feel changes in heat and cold may be impaired as a result of normal and pathological changes of aging. This process can cause older adults to die of the effects of excessive heat or cold. During periods of high temperature and humidity, older people should increase fluid and salt intake, stay in a cool and shaded environment, remain calm, have more rest periods, and refrain from going outdoors when the temperature is higher than 90°F. Sweating, which is reduced in older adults, can be accommodated by the wearing of light-colored, lightweight cotton clothing. If sweating ceases or is inadequate, the older person is at risk of heat stroke. Heat stroke can contribute to sepsis, myocardial infarction, and cerebrovascular accidents, particularly in people with diabetes. Reduced body heat can also present problems in the older adult. Symptoms of and interventions for hypothermia are listed in Box 24-9.

Box 24-9

Nursing Interventions for Hypothermia

Symptoms

- Cold to touch

- Slow respiration
- Bradycardia
- Low blood pressure
- Slurred speech
- Drowsiness
- Temperature 95°F rectally

Interventions

- Warm hands and feet
- Cover with blanket
- Set room temperature to 70°F
- Wear cap to bed at night
- Wear socks to bed at night
- Wear several layers of clothing
- Increase activity
- Decrease alcohol intake
- Use extreme caution with space heaters, heating pads, or electric blankets

Preventing Injury

Falls and fires are leading causes of unintentional injury and death in people 65 years or older. Other unintentional injuries and deaths in older adults are caused by motor vehicle accidents, suffocation, and

poisoning. Because of normal age-related changes and the increased incidence of chronic illness, older adults can experience decreased muscle strength and delayed reaction time and subsequently become more vulnerable to environmental hazards. Decreased sensory acuity and impaired balance further diminish their ability to interpret the environment.

As the percentage of older adults living in the United States increases, the number of older drivers also increases. The CDC (2015d) reported that in 2012 there were approximately 36 million licensed drivers 65 years of age or older. Each day an average of 586 older adults experience an injury from a car crash. Age-related changes in vision, joint mobility, and cognitive changes may affect the older person's ability to drive. Because of these changes, older adults often avoid driving at night, in bad weather, in heavy traffic, on long trips, or on highways or high-speed roads.

Older individuals are at increased risk of severe injury resulting in hospitalization, disability, or death from motor vehicle injuries because of the many changes in their neuromuscular and sensory abilities, which slow response time in emergency situations. In 2008 more than 5500 older adults were killed and more than 183,000 were injured in motor vehicle crashes; older men had a substantially higher death rate than older women. Most traffic fatalities involving older adults occur during the daytime and involve other vehicles. In two-vehicle fatal crashes involving both older and younger drivers, the older driver's vehicle was more than twice as likely to be struck than the younger person's, indicating a decline in defensive driving as opposed to an increase in aggressive driving among older adults. Older drivers involved in fatal automobile accidents, however, had the lowest blood alcohol level.

Older adults are encouraged to take a seniors' driving safety course to learn how aging changes can affect their driving and strategies for safer driving. Nurses working in the community may encourage older drivers to contact the AARP or the American Automobile Association for driving classes designed to meet their needs. In addition, attending these classes often provides savings on vehicle insurance. At some

point, it may be better for older adults to stop driving. Box 24-10 offers warning signs that suggest when an older adult should limit or stop driving. Older adults are often highly resistant to requests to stop driving however, as being able to drive is an important sign of independence. Many families find out only after a car accident that the older adult has not heeded their warning and has been driving without their knowledge. In the case of an older adult with dementia, health care providers may need to talk with family members to find a way to prevent the person from driving. If an older adult has been found to be an unsafe driver and refuses to stop driving, a family member may take away the car keys or mechanically disable the car so that it cannot be driven. It is important, however, to find ways for the older adult to continue to participate in pleasurable activities and not to become isolated. For example, a loss of spiritual connections may occur when older adults can no longer drive to their place of worship. In rural areas, there are many older adults managing farms and dependent on being able to drive to obtain needed supplies and services. Family members or friends may be able to set up a schedule to alternate driving the person to the grocery store, church, and other places. This can also help to provide important social interactions.

Box 24-10

When to Stop Driving

Poor driving skills that are warning signs of unsafe driving include:

- Not using turn signals correctly or not using them at all.
- Having trouble making turns.
- Having difficulty moving into or maintaining the correct lane of traffic.
- Having trouble judging the space between vehicles in traffic on highway entrance or exit ramps.

- Parking inappropriately.
- Hitting curbs when making right turns or backing up.
- Unpredictable stopping in traffic.
- Driving too slowly; other drivers often honk horns.
- Failing to stop at stop signs or stop lights.
- Failing to notice important activity on the side of the road.

From American Association of Retired Persons. (2010). 10 signs that it's time to limit or stop driving. http://www.aarp.org/home-garden/transportation/info-05-2010/Warning_Signs_Stopping.html.

Elder Mistreatment

Elder abuse (elder mistreatment) refers to intentional or neglectful acts by a caregiver or "trusted" person that results in, or may lead to, harm of a vulnerable elder. The National Center on Elder Abuse (n.d.) lists the following forms of elder abuse and mistreatment: physical abuse, neglect, emotional or psychological abuse, verbal abuse and threats, financial abuse and exploitation, sexual abuse, and abandonment. In many states, self-neglect is also considered mistreatment. *Women's Health USA 2010* (USDHHS, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010) reported that in 2004 caregiver neglect accounted for 20.4% of elder abuse and self-neglect account for 37.2%. Emotional or psychological abuse—described as threats or other verbal attacks, isolation, rejection, or denigrating acts that cause or could cause mental anguish, pain, or distress—accounted for 14.8%; financial abuse and exploitation, including theft, fraud, misuse or neglect of authority, and use of undue influence to gain control over an older person's money or property accounted for 14.7%; physical abuse, including the use of physical force that may result in injury, physical pain, or impairment, accounted for 10.7%; and sexual abuse, which includes any type of

nonconsensual sexual contact with an elderly person, including those who cannot give consent, accounted for 1.0%.

Victims of elder abuse are more likely to be single women older than 75 years who are dependent on the caregiver for food and shelter. They are more likely to be frail, to be incontinent, or to have mental disability. The abuser is usually the adult son or daughter of the victim, who has poor impulse control and low self-esteem (Nies & McEwan, 2011). Nurses have a responsibility to identify abuse, provide appropriate care for injuries, and report suspected abuse to appropriate state agencies or law enforcement personnel. The nurse may consult social services to find a more suitable living arrangement for the victim. The most important consideration is to provide a safe environment for the older adult who is in immediate danger.

Biological Agents

Because of decreased immune system response, older adults are susceptible to bacterial and viral disease. In many cases, older adults have not received primary immunization against diphtheria and tetanus. A large emphasis is placed on immunizing young children against communicable disease; however, older adults can also be protected by commonly available vaccines that have been shown to lower both morbidity and mortality. Influenza and pneumonia are two disease processes that are associated with higher mortality and morbidity.

Influenza

Influenza has been a significant cause of morbidity and death in older adults. In 2009, there were 638 deaths from influenza and 42,831 deaths from pneumonia in people aged 65 years or older (CDC, 2011c). In 2010, the hospitalization rate for influenza among older adults 65 years of age or older was 62.1 per 100,000. The CDC reported that influenza vaccination levels among older adults was 65% to 70% in 2011–12 (Lu et al, 2013), but this was less than the *Healthy People 2010* target of 90%. The vaccine, composed of

inactivated whole virus or viral subunits grown in chick embryo cells, is given annually to older adults, especially those with chronic conditions such as pulmonary or cardiac problems and those in long-term care facilities. Vaccination is contraindicated in people who have experienced a reaction to the vaccine, and caution must be exercised in administering the vaccine to people who have allergies to eggs. A *Healthy People 2020* objective (IID-12-7 and IID-4-2) is "to increase the percentage of older adults who are vaccinated annually against influenza and to decrease the incidence of pneumococcal infections among older adults to 31 new cases per 100,000" (USDHHS, 2012c).

Pneumococcal Infections

Deaths from pneumococcal infections declined in previous years, indicating the value of public health initiatives to make information widespread about the importance of immunization against pneumonia and influenza. Implementation of immunization programs in public places such as supermarkets and drugstores, in addition to physicians' offices and clinics, has enhanced access to this preventive measure. Nevertheless, many older adults remain unvaccinated. The CDC recommends that adults aged 65 years or older receive the pneumococcal vaccination. It is important that nurses inform the public about the importance of immunizations and counteract the myth that receiving the vaccination will result in the disease, which often prevents older adults from receiving immunization.

Cancer

Cancer rates for older adults are disproportionately high in the United States. Although only 12% of the population are considered older adults, more than 50% of all diagnosed cancers are found in this population, and the death rate for cancer is highest among adults aged 65 years or older. The reason for the large proportion of cancer in the United States is unknown. Theories include longer exposure to carcinogens, increased susceptibility to cancer in the older body,

decreased cellular healing ability, loss of tumor-suppressing genes, and decreased immune function. Although the exact cause cannot be determined, cancer is a significant problem for older adults in the United States.

The types of cancer common to older adults are listed by sex in Table 24-3. Prostate cancer is the leading cancer among men of all races and ages and is clearly the most common male cancer and the second leading cause of death from cancer in men in the United States. It is estimated that 8% of all men in the United States will receive a diagnosis of prostate cancer during their lifetime. Early detection of prostate cancer allows treatment while it is still localized in the prostate gland and highly curable. Evidence suggests that by use of a combination of screening techniques, more cases of prostate cancer can be detected earlier. There are three key components of an appropriate prostate screen: symptomatology, prostate-specific antigen level measurement, and a digital rectal examination. The four major treatment options for prostate cancer are surgery, radiation therapy, watchful waiting, and hormone therapy.

TABLE 24-3

2010 Estimated US Cancer Deaths

	Men (*N*/%)	Women (*N*/%)
All causes	299,490	270,290
Oral cavity and pharynx	5430/0.018	2450/0.009
Digestive system	79,010/0.263	60,570/0.224
Respiratory system	89,550/0.299	72,120/0.266
Bones and joints	830/0.002	630/0.002

From American Cancer Society. (2010). Cancer facts & figures 2010. Atlanta, GA: American Cancer Society.

http://www.cancer.org/acs/groups/content/@epidemiologysurveilance/documents/d
026238.pdf; Murphy, S. L, Xu, J., & Kochanek, K. D. (2012). Deaths: Preliminary data for 2010. *National Vital Statistics Reports, 60*(4). http://www.cdc.gov/nchs/data/nvsr/nvsr60/nvsr60_04.pdf.

Breast cancer is the most common cancer in women of all ages and races in the United States. It is surpassed only by lung cancer as the cause of death in women. Reports suggest that one in nine women will develop breast cancer in their lifetime. Three-quarters of all breast cancers occur in women older than 50 years. The risk is increased in women whose close female relatives (mothers or sisters) have had the disease. Women who have never had children or who had their first child after age 30 years appear to have an increased risk. The causes of breast cancer remain unclear. The best protection is early detection and prompt treatment. New guidelines from the American Cancer Society (2015) recommend that women aged 55 years or older have mammograms every 2 years, although they may continue to have annual screening if they wish.

Nurses help older adults change the habits that place them at high risk of developing cancer. Following nutritional guidelines (as suggested earlier in this chapter), reducing stress, adopting a program of regular exercise, and stopping smoking and other use of tobacco products are a few of the approaches that nurses can advise to promote individual wellness. Periodic monitoring and screening in the form of regular visits to a primary health care provider or community screening can alert older adults to early signs and symptoms of cancers that occur during the later years.

Chemical Agents

Chemical agents can be both therapeutic and harmful depending on their use. The increased use of prescription and over-the-counter medications can result in increased adverse drug events. The use of alcohol and tobacco products can be especially harmful for older adults.

Drug Use

Normal changes of aging have a significant effect on the pharmacodynamics of drugs in older adults. The ways in which medications are absorbed, distributed, metabolized, and excreted from the body are affected by normal physiological changes and by illness. Even when medications are taken as prescribed, age-related changes and disease increase the risk of undesirable side effects. Older adults are more likely to take multiple medications, resulting in increased risk of serious drug interactions. In addition to potential adverse effects caused by prescription drugs, older adults take many types of nonprescription substances, including over-the-counter medications; vitamins, minerals, and supplements; herbal remedies; and foods and other traditional remedies used to resolve common ailments. **Polypharmacy**, or the use of multiple medications for the same or for different health problems, is a major concern for older adults. Approximately one-third of older adults in the United States take five or more prescription drugs (Brookes & Scott, 2015). The higher rate of polypharmacy in older adults as compared with younger groups is related to increased health problems in older adults and new medications that effectively treat these conditions. The Beers criteria (American Geriatric Society, 2015), developed from the Health Care Financing Administration *Guidelines for Potentially Inappropriate Medications in the Elderly,* present medications known to place older adults at risk of adverse reactions.

Many older adults who reside at home take their medications independently. Although self-medication with prescription and nonprescription substances is an effective method of disease management, little is known about the process of taking medications after the person leaves the health care practice or facility. Although it is generally assumed that medications are taken as prescribed, sensory disturbances; lack of knowledge; and alternative drug, alcohol, and nutrition practices may present challenges to medication self-administration that interfere with medical management of health problems. Nurses should take a thorough medication history to assess the individual for past drug reactions and identify all currently prescribed and nonprescription substances taken. New medications

should be started at their lowest effective dose, and the dose should be increased slowly as necessary.

One of the major barriers to drug adherence in the older adult is affordability. Medicare provides prescription drug coverage to everyone eligible for Medicare under Medicare Part D. One can get Medicare drug coverage in one of two ways: a Medicare Prescription Drug Plan (PDP) or a Medicare Advantage Plan (preferred provider organization [PPO] or health maintenance organization [HMO]). For poor older adults, assistance for the purchase of prescription drugs is available in several ways: switching coverage to a less costly drug plan; or applying for assistance to pharmaceutical company assistance programs, state pharmaceutical assistance programs, national- and community-based charitable programs, and the Extra Help program through Medicare and Social Security.

Alcohol and Drug Abuse

Substance abuse among Americans aged 60 years or older, including misuse of prescription drugs, is estimated to affect approximately 17% of older adults (Hazelden Betty Ford Foundation, 2015). By 2020 it is anticipated that the number of older adults with substance abuse problems will double. Forty percent of adults aged 65 years or older drink alcohol (National Institute on Alcohol Abuse and Alcoholism, n.d.). Alcohol and drug abuse problems among older adults have been underestimated. In Americans aged 65 years or older, excessive alcohol use, including binge drinking, accounts for more than 21,000 deaths each year (Rubin, 2014). Older adults may be classified as moderate drinkers but frequently consume large amounts of alcohol at a time.

Alcohol and drug abuse in older adults is often unreported and unnoticed because the symptoms can be similar to those of other common problems of aging, and health care providers often do not ask people about alcohol or nonprescription drug use. The longer the problem remains undetected, the greater it becomes and the more the potential harm related to other chronic health problems.

Older adults are more vulnerable to the effects of alcohol and illicit

drugs because their detoxification and excretion systems are not as efficient as those of younger people. Alcoholism and drug abuse predispose older adults to accidents and injury, cognitive decline, physical debility, nutritional deficiencies, disease, and decreased function. Additionally, alcohol use while taking medications can interfere with the desired effect of the medication.

Tobacco Use

Tobacco use includes cigarette smoking, cigar smoking, pipe smoking, and chewing tobacco. Use of tobacco products is associated with cardiovascular disease, several types of cancer, and chronic lung disease (CDC, 2015e). Some older men and women today may be the first generation to have smoked throughout their lives, starting in their teens or 20s when smoking seemed fashionable. The results of smoking occur slowly over time, and problems are usually not experienced until signs and symptoms of smoking-related health problems occur. Because smoking can initiate and promote disease processes, it is one of the most important negative predictors of longevity. Smoking is a particular problem for older adults because of the large number of medications they take and the potential for drug interactions. Nicotine-drug interactions can potentiate or interfere with a desired drug effect.

Older adults can experience the benefits of smoking cessation even after the age of 65 years. These people may be more motivated to quit smoking than when they were younger, because they are likely to see some of the damage that smoking has caused and anticipate that smoking cessation will restore or improve their health. Nurses can assist older adults in making the commitment to quit smoking through education and referral to smoking cessation programs.

Determinants of Health

Social Factors and Environment

The incidence of chronic and acute illnesses, the subsequent decline in functional status, changes in economic status, and changes in family structure frequently place older adults in situations for which they are admitted to acute care facilities or must make a temporary or permanent move into a residential facility or a long-term care facility. When providing health-promotion services to older adults, nurses must take into account the type of setting in which the person lives. Box 24-11: Research For Evidence-Based Practice provides helpful information about transitional care for older adults with chronic illness, as well as their caregivers.

Box 24-11

Research for Evidence-Based Practice

Evidence-Based Transitional Care for Chronically Ill Older Adults and Their Caregivers

Unplanned readmissions within 30 days of discharge are estimated to be at 90%. A multidisciplinary research team developed a transitional care model (TCM) to focus on the needs of very high risk chronically ill older adults who are transitioning from the hospital to the home following an acute illness. The TCM is led by an advanced practice nurse (APN) using a holistic person-centered and family care–centered approach. The APN acts as the "point person" throughout the episode of care, facilitating timely exchange of information across all settings. The criteria identified to determine high-risk persons include those who are 80 years or older, those who have moderate to severe functional deficits, and those who are unable to complete self-care or manage daily tasks.

The tools used to assess potentially affected persons include the

Hospital Admission Risk Profile, the Katz Index of Independence in Activities of Daily Living or the Lawton Instrumental Activities of Daily Living Scale, and the Mental Status Assessment of Older Adults (Mini-Cog). Potentially affected persons are also screened with use of the Geriatric Depression Scale—Short Form to assess symptoms of depression. The following risks associated with readmission have been identified: having four or more active coexisting health problems, being treated with six or more prescribed standing medications, having two or more hospitalizations within the previous 6 months, being hospitalized within the previous 30 days, having been hospitalized with baseline dementia, being treated for delirium, lacking formal or informal family caregiver support, and having low health literacy.

With APN services under the TCM, mutual goals are developed, there is improved communication and collaboration among health care providers, there is improved medication and dietary adherence, there are decreased numbers of rehospitalizations during the 52 weeks of follow-up, and there is high person, caregiver, and physician satisfaction. The barriers to widespread adoption of the TCM identified include the organization of current systems of care, barriers of regulation, lack of quality and financial incentives, and culture of care issues.

From Bixby, M. B. (2011). Evidence-based transitional care for chronically ill older adults and their caregivers. *Journal of Geriatric Care Management*, *21*(2), 20–24.

When older adults leave their homes, they may enter a continuum of care extending from an independent living center and assisted living facilities to skilled care facilities or nursing homes, with possible short-term stays in acute care settings. Nurses who work in each of the settings on the continuum can promote health to this population in many ways. From the acute care setting through each stage of the continuum, opportunities are available for nurses to introduce older adults and their families to community resources (Table 24-4). The acute care nurse has the opportunity to present health-promotion strategies at a time during which individuals may

perceive the greatest need to change their lifestyle behaviors so that they can return to an improved health state. In most cases an acute care admission is an opportunity to introduce health-promotion teaching. However, the acute care nurse may feel frustrated by the inability to see the results of this teaching and may therefore give it a low priority in the care plan.

TABLE 24-4

Long-Term Care Housing and Assessment Continuum

	Independent Living	Retirement Community	Assisted Living	Nursing Facility
Description	Covers a broad range of housing options (residential houses, apartments, condominiums, townhouses, subsidized senior housing) for older people who are functionally and socially independent	Provides a living arrangement that integrates shelter and services for older people who do not need 24-h protective oversight	Provides a living arrangement that integrates shelter and services for frail older people who are functionally and/or socially impaired and require 24-h protective oversight	Provides a living arrangement that integrates shelter with medical, nursing, psychosocial, and rehabilitation services for older people who require 24-h nursing supervision
Primary services	**A** Environmental security Possibly coordination of resident services (transportation, activities, housekeeping) Or no services are available	**B** A plus: Meals (one to three per day) Transportation Activities Housekeeping assistance Assistance with coordination of community-based services	**C** A and B plus: Assistance with activities of daily living Medication monitoring, 24-h protective oversight	**D** A, B, and C plus: Medication administration, 24-h nursing supervision
Mobility	Capable of moving about independently *OR* ambulatory with cane or walker Independent with wheelchair, but needs help in an emergency	Capable of moving about independently Able to seek and follow directions Able to evacuate independently in emergency *OR* ambulatory with cane or walker Independent with wheelchair, but needs	Mobile, but may require escort or assistance resulting from confusion, poor vision, weakness, or poor motivation *OR* requires occasional assistance to move about, but is usually independent	May require assistance with transfers from bed, chair, and toilet *OR* requires transfer and transport assistance Requires turning and positioning in bed and wheelchair

		help in an emergency		
Nutrition	Able to prepare own meals; eats without assistance	Able to prepare own meals; eats without assistance. Generally, a minimum of one meal a day is available	All meals and snacks are provided. May require assistance getting to dining room or requires minimal assistance (opening cartons or other packages, cutting food, or preparing trays)	May be unable or unwilling to go to dining room. May be dependent on staff for eating or feeding needs *OR* may be fully dependent on staff for nourishment (includes reminders to eat)
Hygiene	Independent in all care, including bathing	Independent in all care, including bathing and personal laundry	May require assistance with bathing or hygiene *OR* may require assistance, initiation, structure, or reminders. Resident may be able to complete tasks	May be dependent on staff for all personal hygiene
Housekeeping	Independent in performing housekeeping functions (includes making bed, vacuuming, cleaning, and laundry)	Independent in performing housekeeping functions (includes making bed, vacuuming, cleaning, and laundry) *OR* may need assistance with heavy housekeeping, vacuuming, laundry, and linens	Housekeeping and laundry services provided	Housekeeping and laundry services provided
Dressing	Independent and dresses appropriately	Independent and dresses appropriately	May require occasional assistance with shoelaces, zippers, or medical appliances or garments *OR* may require reminders, initiation, or motivation	May be dependent on staff for dressing
Toileting	Independent and continent	Independent and completely continent *OR* may have incontinence, colostomy, or catheter, but independent in caring for self through proper use of supplies	Same as for retirement community *OR* may have occasional problem with incontinence, colostomy, or catheter and may require assistance in caring for self through proper use of supplies	May have problem with incontinence, colostomy, or catheter and requires assistance *OR* may be dependent and unable to communicate needs
Medications	Responsible for self-administration of all medications	Responsible for self-administration of all medications *OR* may arrange for family or home health agency to establish a medication	Able to self-administer medications *OR* facility staff may remind the person about or monitor the	Medications administered by staff personnel or self if assessed as capable

		administration system	actual process *OR* facility staffed by registered nurses or licensed practical nurses who administer medications	
Mental status	Oriented to person, place, and time Memory intact, but has occasional forgetfulness *AND* able to reason and plan and organize daily events. Mentally capable of identifying needs and meeting them	Oriented to person, place, and time *AND* memory is intact, but has occasional forgetfulness without consistent pattern of memory loss *AND* is able to reason and plan and organize daily events. Mentally capable of identifying environmental needs and meeting them	May require occasional direction or guidance in getting from place to place *OR* may have difficulty with occasional confusion that may result in anxiety, social withdrawal, or depression *OR* orientation to time or place or person may be impaired	Judgment can be poor and may attempt tasks that are not within capabilities *OR* may require strong orientation and reminder program. May need guidance in getting from place to place *OR* disoriented to time, place, and person *OR* memory is severely impaired
Behavioral status	Deals appropriately with emotions and uses available resources to cope with inner stress	Deals appropriately with emotions and uses available resources to cope with inner stress *AND* deals appropriately with other residents and staff *OR* may require periodic intervention from staff to resolve conflicts with others to cope with situational stress	May require periodic intervention from staff to facilitate expression of feelings to cope with inner stress *OR* may require periodic intervention from staff to resolve conflicts with others to cope with situational stress	May require regular intervention from staff to facilitate expression of feelings and to deal with periodic outbursts of anxiety or agitation *OR* maximal staff intervention is required to manage behavior

Some older adults will rapidly grasp material that they believe will prevent future hospital admissions and restore their health. Home health nursing appointments, transportation services, housekeeping services, adult day care, and assistance with grocery shopping or home-delivered meals will help older adults return to the home environment better prepared to recover from the illness. Helping older adults and their families locate adult day care programs, smoking-cessation programs, stress-management workshops, or weight-loss and exercise programs before leaving the hospital will encourage older adults to enter these programs immediately after discharge, while they are motivated.

Long-term care nurses are able to locate and plan community

resources during the resident's stay. Some community services will enable an older person to return home to an environment in which active health promotion continues. Community resources that may help older adults who are discharged from long-term care facilities include adult day care programs, support groups and medical resources, telephone and Internet information, and referral services. In addition to their role in individual care planning, long-term care nurses can be more involved in institutional policy changes. Recommendations about smoking policies, healthy diets, and exercise programs may prompt interdisciplinary changes that will result in improved health for the entire institution.

The geriatric care manager who visits older adults in their homes or in other residential facilities may be charged with individual health-promotion planning. Home care nurses provide health care information and services to individuals and their families. The resources available to community health nurses are frequently rich and enable the nurses to draw on a variety of sources to assist in promoting the health of community-dwelling older adults. Transportation options, home-delivered meals, assistance with housekeeping, socialization activities, exercise programs, and self-help groups are only a few of the health-promotion resources available within the community. Nurses in all settings can consult a social worker or contact the community older adult services office for information on available resources.

It is important for the nurse to consider the health literacy level of the older adult and their family when providing information and health teaching. The USDHHS (n.d.) defines **health literacy** as "the degree to which individuals have the capacity to obtain, process, and understand basic health information needed to make appropriate health decisions and services needed to prevent or treat illness." People who are at risk of low health literacy are the elderly, minorities, people of low socioeconomic level, and the medically underserved. Older adults with low health literacy may have difficulty finding appropriate health care providers, seeking preventive health care, filling out health forms, managing chronic

illness, following directions, understanding the relationship between risk behaviors and health problems, and following medication and treatment plans. It is important for nurses to identify older adults who have low health literacy and develop instructional materials that use simple language and short sentences, avoiding or defining technical terms. Nurses can provide assistance for older adults who have difficulty completing forms. For older adults who have limited English skills, written and oral instruction can be provided in their native language.

In recent years there has been a substantial increase in the use of palliative and hospice care by older adults. Palliative care is provided for people with a serious illness who will continue to receive curative treatment and symptom relief. Whereas palliative care is available to anyone with a serious illness, hospice care requires a terminal prognosis with an expected death within 6 months. Once the person is placed in hospice care, treatment to relieve pain and other symptoms is continued but the person and his or her physician have decided to end all curative treatment. In 2011 approximately 1.65 million persons received hospice care (National Hospice and Palliative Care Organization, 2012). In 2010 there were 5150 hospice providers in the United States. Of approximately 2.5 million deaths in the United States in 2010, slightly more than 1 million, or 42%, died under hospice care. Most hospice care provided in 2010 was in the person's home (41.1%), followed by a hospice inpatient facility (21.9%), nursing home (18%), and acute care hospital (11.4%). Most hospice care recipients were female (56.1%), white (77.3%), and 65 years or older (82.7%). Hospice services provided include direct clinical care for individuals and bereavement services for the person and the family (National Hospice and Palliative Care Organization, 2012).

People in a hospice are empowered to live with dignity, alert and free of pain. The goal of hospice care is to facilitate a “good death” for individuals. Families and loved ones are consistently engaged in caregiving for the dying and helping them maintain the highest possible quality of life. The hospice environment promotes quality of life within the context of differing cultural and spiritual values and

beliefs. Nurses in all settings may identify and refer individuals for palliative or hospice care and facilitate use of these services to promote wellness during serious or terminal illness.

Older adults can be overwhelmed with the amount of advertising that is directed at them about such "necessities" as nutritional supplements, drugs, hearing aids, alarms to use if they fall, phones, Internet sites, and digital devices. Nurses can help them sort out the confusion related to this advertising and direct them to reliable sources of information. The AARP provides many services to people older than 50 years, including excellent educational materials and community program packages. The topics reflect a broad range of concerns and are generally presented in a self-help manner. Among the topics covered are smoking, exercise, nutrition, and wellness. Each program serves as a guide to negotiate a system or learn more about a health problem. These topics are written in lay terms (in easily understood language) and are printed in large print to accommodate vision changes. This self-help method is especially important for those who feel uncomfortable addressing questions on finances or sexuality to nurses and physicians.

The National Institute for Aging (http://www.nia.nih.gov) conducts research to examine many aspects of aging so as to improve the quantity and quality of life in older years. It provides free educational publications called *Age Pages* that can be given to older adults to help them adapt safely and successfully to the many changes and concerns encountered as a person ages. *Age Pages* are easily accessed on the Internet and are written in large font and language easily understandable to the lay public.

Two additional environments of care emerged in the United States in the second half of the 20th century: continuing care retirement communities (CCRCs) and assisted living facilities (ALFs). CCRCs are full-service communities offering long-term contracts that provide older adults with a continuum of care, extending from retirement services through assisted living to skilled nursing, all in one location. The mission behind CCRCs is "aging in place." CCRCs are expensive and require an entrance fee and a monthly payment. Residence in a

CCRC requires commitment to a long-term contract that specifies the housing, services, and nursing care provided. ALFs are defined as homelike settings that promote resident autonomy, privacy, independence, dignity, and respect while providing necessary support. The lower cost of ALFs in comparison with skilled nursing facilities and the greater emphasis on functional autonomy make these facilities appealing to older consumers and their families. Although residents of ALFs have many long-term health care needs, it is important to understand that the role and availability of nurses in these facilities differ greatly by state guidelines.

One additional social factor should be considered—that of age discrimination. Even today when many older adults are active contributors to society, they experience discrimination in seeking employment and in many other areas. Older adults have described situations where they seek medical care and instead of health care providers speaking directly to them, they direct their inquiries to a family member who is present. Many of these older adults are highly educated, cognitively aware, and perfectly capable of implementing advice from health care providers to maintain their health. Getting old should not carry a stigma. Older adults are in a position to enrich the lives of others through the wealth of knowledge and experience that they have accumulated through the years.

Diversity Awareness

The percentage of white older adults is expected to decrease from 1990 to 2030, whereas the percentages of black, Asian, and Hispanic older adults are expected to increase. These changes in the diversity of the United States bring unprecedented challenges to the US health care delivery system. Challenges will continue to present themselves in the way that each culture perceives the status of the older person within society, the way health is maintained or improved, the causes and meanings of disease throughout life, and the ways in which disease and injury are managed from the cultural perspective versus how they are managed according to the health care system.

Nurses must be aware of the cultural diversity of older adults for

whom they care and the cultural beliefs that influence health care decisions of older adults. Cultural competence refers to the ability of nurses to understand and accept the cultural backgrounds of individuals and provide care that best meets the persons' needs, not the nurses' needs. To develop cultural competence, the first step is to examine personal beliefs and the effect of these beliefs on professional behavior. Nurses may best accomplish this by conducting personal cultural assessments. After identifying personal cultural biases that influence care, nurses must bracket these beliefs to make sure they do not affect delivery of care. After this step has been accomplished, it is important to increase understanding about population-specific health-related cultural values, beliefs, and behaviors. It is important to remember that although an older person may be part of a cultural group, the individual may have become acculturated while living in the United States. A cultural history is therefore an essential first step in determining the person's health care beliefs and practices. When conducting cultural assessments, the nurse must remember that some of the standardized assessment tools, such as the Geriatric Depression Scale and the MMSE, are available in languages other than English. Caution must be taken in interpreting a tool that has not been formally translated, because the meanings of many words and phrases may not have an appropriate translation. The nurse must also be cautious when using assessment tools that have not been tested and validated with people of different cultures and nationalities.

The final stage in attaining cultural competence is to develop skills for working with culturally diverse populations. This entails the development of knowledge in working with culturally diverse populations and consistently using those skills with older adults. Conducting cultural assessments, using translation services, and providing culturally competent care are integral components to developing culturally competent institutions and improving care.

Levels of Policy Making and Health

This chapter has attempted to emphasize the need for health-promotion services for older adults. Governmental efforts to improve

health promotion and illness/injury prevention continue. The Affordable Care Act of 2010 (http://www.healthcare.gov) strengthens Medicare by providing important new benefits, including free or low-cost preventive services, free annual wellness visits, and a discount on prescription drugs for Medicare recipients in the "donut hole." Older adults continue to be able to choose their own physician. Preventive immunizations include those for influenza, pneumonia, and hepatitis B. Preventive screening examinations include those for diabetes, cholesterol and cardiovascular diseases, colorectal cancer, breast cancer, cervical cancer, and prostate cancer. Counseling services for smoking cessation and for medical nutrition therapy for those with diabetes or kidney disease are also provided.

Medicare and other federal expenditures for older adults (direct or indirect) constitute a large part of the federal budget. Most goes to old age and retirement programs, disability programs, and Medicaid. Because of the large percentage of the federal budget consumed by Medicare, this insurance program is undergoing much scrutiny. Legislation to more effectively manage or cut the Medicare budget is under review. Lawmakers anticipate that approximately $49 billion in savings could come from more effective use of health maintenance organizations and prospective payment systems instituted in the home. Regardless of the nature of funding cuts, illness and injury prevention contributes to financial stability of the older adult. Nurses continue to play a key role during the years of Medicare reform in promoting health not only to prevent illness and injury but also to prevent older adults from losing all their savings and becoming impoverished.

Medigap policies have been promoted to pay for the health care coverage not afforded by Medicare. The various policies provide differing levels of coverage. Choices about whether to purchase coverage for durable health care supplies, prescription medications, and other medical charges must be made to select the most appropriate policy. The charge for the policy varies according to the level of coverage selected.

Nongovernmental organizations also influence policy decisions

affecting older adults and health. Professional health care provider organizations such as the American Nurses Association, the National Gerontological Nurses Association, and the American Medical Association conduct research to determine best practices in elder care and to provide information to policymakers. The ARAP and the Gray Panthers are examples of two consumer organizations that gather information, fund research related to issues of older adults, and act as advocates for older adults in policy making organizations.

Health Services/Delivery Systems

Unfortunately, many people are not financially prepared for older adulthood. Although some individuals receive supplemental income from pensions or individual retirement accounts, many do not, and the amount of income from these sources is often very limited. Most older adults live on limited incomes. Several resources are available to help those with limited finances live quality lives. Medicaid, authorized by Title 19 of the Social Security Act, is designed to help older adults who are receiving public assistance pay for medical expenses. Both federal and state governments fund the Medicaid program. To qualify for Medicaid, an individual must have limited income and assets. The coverage afforded by Medicaid is more extensive than that of Medicare. For example, Medicaid covers stays in long-term care facilities, transportation for health care visits, and prescription drug services. Medicare covers these services in limited and medically acute situations. Frequently older adults and their caretakers desire the more extensive coverage provided by Medicaid. These individuals are required to "spend down" their assets to be eligible.

Careful financial planning before the onset of illness is ideal to avoid the need to spend down assets and to help the older adult live at a desirable income level. This task can be accomplished through meetings with lawyers and financial planners as early in life as 30 years of age. Completing advance directives, including naming a conservator in advance of illness, assists caregivers, physicians, clergy, and the family in making difficult decisions at the end of life, when

the affected person is no longer able to make them. The better prepared the older adult is, the easier it is to receive appropriate care and treatment during times of illness. Reverse annuity mortgages are one option for increased income during the later years. A reverse annuity mortgage is obtained when a bank or private business purchases the home of an older adult. The bank pays the person a set amount of money each month until the house is paid for in its entirety. The older adult continues to live in the home. This approach provides the person with necessary funds and negates the need to move and sell the house if an illness arises. When the older adult (mortgagee) dies, the bank or mortgager then owns the property.

Long-term care insurance is an option for those planning for the possibility of long-term care. As with other insurance programs, younger adults can purchase a policy, now widely available from insurance agents. A premium is paid each month that entitles the beneficiary to receive long-term care benefits at home, in an assisted living facility, in a day care facility, or in a long-term care facility. Older individuals are cautioned to explore the many options available for this type of insurance. The benefits and coverage differ, and exclusions are frequently written into the contract to prevent care in certain situations. An important feature of these policies is the option to hire a personal caregiver if the need arises.

Because population shifts have created a large number of older adults in the United States, political movements toward protecting the rights of older adults are abundant and strong. Nowhere is there more political activity than among the groups responsible for social policy and aging. However, this has created problems of consistency, equity, and authority. Several large programs, including those directed by the Social Security Administration, the Health Care Financing Administration, and the Department of Veterans Affairs, have coordination problems because of their size and the large number of cases they handle.

The nurse who specializes in the care of older adults helps a great deal to promote their health and well-being through education, research, and practice. Educational curricula must be evaluated

continually to ensure that content is appropriate and accurate with respect to aging. The quality of care depends on the clinician's knowledge base. Education for the older person is equally important and begins with an assessment of the individual's level of understanding of health-promotion activities.

Health-promotion and illness/injury-prevention research for this population is only beginning. Much more remains to be done in exploring the concepts of health promotion, relating these concepts, and developing and testing hypotheses. Research is needed to debunk commonly held beliefs, myths, and stereotypes about aging. Defining some of the concepts of health promotion, such as quality of life and functional ability, will yield immeasurable amounts of information that can be tested. Eventually, with the commitment of qualified nurses, health promotion will be respected for the integral role it plays in the quality of life of older adults.

Nursing Application

Nurses in a position of providing care to older adults focus on promoting quality of life, promoting the health of the population, maintaining self-care, and preventing disease and its complications. Nursing activities with the older adult often focus on the management of chronic conditions. While concentrating on healing, the nurse delivers care in a holistic manner that addresses the functional and psychosocial needs of the older adult.

Nurses assist older adults by engaging them in health-promotion activities. Some of the major areas of focus are healthy weight and diet, activity, fall prevention and home safety, and medical appointments for screening. Pneumococcal and seasonal influenza immunizations are extremely important for the older adult. Additionally, the older adult is educated about cancer screenings and other screenings aimed at detecting diabetes, late-onset heart disease, osteoporosis, and hypertension. An effective method of ensuring that older adults participate in screenings is to coordinate health fairs in senior centers. The nurse is able to provide a common location where the older adult can obtain vaccinations, necessary education, blood pressure checks, and fingerstick glucose monitoring. The nurse offers counseling as needed and refers the older adult to his or her primary care provider for follow-up.

Case Study

Unsafe Driving: Larry Johnson

Larry Johnson, a healthy 75-year-old man, lives in his own apartment and is completely independent in activities of daily living and instrumental activities of daily living. Last Friday morning, Larry left his apartment complex at 8:00 AM to go to the store. While backing out of his driveway, he failed to see a school bus passing on the intersecting street, and his car struck the bus. Although no one was

injured, this incident indicated the need for a sensory and neurological assessment. The assessment revealed both hearing and visual deficits.

Reflective Questions

- What would the nurse do to help with the results of the assessment?
- Should this person undergo further neuropsychological tests?
- How best can the nurse support this person during this difficult time in his life?
- In what ways might the family be helpful in this situation?

Care Plan

Unsafe Driving: Larry Johnson

***NURSING DIAGNOSIS: Risk of injury related to unsafe driving**

Defining Characteristics

- Altered response time
- Change in vision or hearing

Related Factors

- Past accident
- Stressful life events
- Receipt of traffic tickets
- Witnessed poor driving

Expected Outcomes

- Person will have realistic expectations of ability to drive.
- Person and nurse will set appropriate limitations on driving.
- Person will take a driver refresher course.
- Family will help to monitor driving competencies.
- Person will have no further accidents.

Interventions

- Assist Larry in registering for a renewal driving program.
- Meet Larry and a family member to discuss ways to ensure consistent safe driving.
- Assist Larry in finding alternative modes of transportation until visual and hearing alterations are corrected and instead of driving in the evening.
- Schedule hearing and vision appointments for Larry and assist in transportation to appointments.

---

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

Life expectancy is now beyond 75 years for both men and women, with the fastest-growing age group being those older than 85 years. This phenomenon is indeed wonderful. However, as noted at the beginning of this chapter, aging is not for sissies. The aging process causes physiological changes in many body functions, and older adults have a higher frequency of illness than the younger population. The many physical, emotional, and role changes of aging are complicated by the increased diversity in cultural and spiritual backgrounds. Older adults who have immigrated to the United States have brought with them different languages, values and beliefs, spiritual patterns, eating habits, views toward modern medicine, and other customs foreign to US culture. Culturally competent health-promotion services are integral to helping older adults lead high-quality lives throughout their extended life spans.

Some of the dysfunctional aspects of aging have extrinsic causes, such as environmental pollution. Older adults are as susceptible as any age group to society's problems, such as homelessness, mistreatment, and drug and alcohol abuse. In conjunction with physiological and pathological changes, multiple acute and chronic diseases can result. Internal and public policy changes will continue to help older adults live in a world in which old age can be the most rewarding stage of life.

Many problems of old age are related to lifestyle. Changes in nutritional needs, sleep patterns, and activity level are required to adapt to normal and pathological processes. Psychological health depends on reassessing spirituality, self-concept, and role functions. Change and adaptation are possible. Aging healthfully is hard work, but with the assistance of nurses and other health care professionals, older adults can be empowered to live their final years with a sense of peace in their life review of happy memories and accomplishments.

UNIT 5
Emerging Global Health Issues

OUTLINE

25 Health Promotion for the 21st Century Throughout the Life Span and Throughout the World

25

Health Promotion for the 21st Century

Throughout the Life Span and Throughout the World

Ratchneewan Ross, Rosanna F. Hess

OBJECTIVES

After completing this chapter, the reader will be able to:

- Identify global trends and directions for health promotion and disease prevention including immunization programs.
- Discuss recent and emerging infectious disease including Ebola virus disease, Zika virus disease, human papilloma virus and cervical cancer, and methicillin-resistant *Staphylococcus aureus* infection.
- Describe problems and implications related to HIV/AIDS.
- Discuss problems and implications related to violence.
- Discuss problems and implications related to bioterrorism and terrorism.

KEY TERMS

Anthrax (*Bacillus anthracis*)

Bioterrorism

Botulism

Ebola virus

Essential public health services

Human immunodeficiency virus

Human papilloma virus

Malnutrition

Methicillin-resistant *Staphylococcus aureus*

Plague

Self-abuse

Smallpox *(Variola major*)

Suicide

Terrorism

Violence

World Health Organization

Zika virus

Think About It

Human Papilloma Virus Infection and Cultural Practices

- *Adila lives in Ghana, West Africa, with her husband and her two daughters, aged 13 and 10 years. Adila learned 6 weeks ago that she has cervical cancer. When Adila told her husband that she had cervical cancer and needed treatment, he accused her of having sexual relations with another man and refused to give her money. He also refused to have his daughters vaccinated against human papilloma virus (HPV), which would prevent them from contracting cervical cancer. He said that this immunization would make them more sexually promiscuous as teenagers.*

- What kind of problems would you anticipate that Adila will encounter if she does not have treatment for her cervical cancer?

- How could Adila's husband be encouraged and educated to change his mind about his wife and daughters?

- What do you think could be done in this Ghanaian village to prevent further HPV infections *in addition* to an immunization campaign?

Visit the World Health Organization website (http://www.who.org) to identify the incidence and prevalence of HPV and cervical cancer in West African countries.

In the new millennium, the gap in life expectancies between people in developed and developing cultures has been widening. In many developed nations, such as Japan, France, Monaco, and the United States, people have a life expectancy at birth ranging from 80 to 89 years, whereas residents of some countries, such as Chad, Guinea-Bissau, and Afghanistan, can have a life expectancy as low as 49 to 50 years (Central Intelligence Agency [CIA], 2015a), attributable primarily to political instability and a high level of poverty, high rates of **human immunodeficiency virus (HIV)** infections, and low quality of life (CIA, 2015a,b; Joint United Nations Programme on HIV/AIDS [UNAIDS], 2014).

In 2012 there were 56 million deaths worldwide; 68% were due to noncommunicable diseases (cardiovascular diseases, cancer, respiratory diseases, and diabetes); more than 48% occurred in low- to middle-income countries, with a disproportionate rise in low-income countries. Almost 10 million children younger than 5 years died in 2015, a steady decline since 2000, but still a rate of 16,000 per day (WHO, 2015a). The mortality rate of children younger than 5 years was 11 times higher in low-income countries than the average rate in high-income countries (WHO, 2015a). On the basis of WHOs 2012 statistics, lower respiratory tract infections, HIV/AIDS, diarrheal diseases, and stroke were the leading causes of death for people in low-income countries, whereas ischemic heart disease and stroke were the leading causes of deaths in lower-middle-income, upper-middle-income, and high-income countries (WHO, 2015b) (Box 25-1: Quality

and Safety Scenario).

Box 25-1

Quality and Safety Scenario

HIV Education for Migrants From Russia

A study examined male migrant workers' sexual behavior in St. Petersburg, Russia ($n = 499$), and revealed that 30% of these migrants reported having multiple female partners in the last 3 months. Condom use with their partners was reported to range from 35% to 52%. When asked about their knowledge of health risks in three major areas, central European migrant workers had the lowest levels of AIDS knowledge, followed by knowledge of the dangers of substance use, and the risks of unhealthy sexual activity. This group also reported high levels of depression and poor social support. In contrast, eastern European migrant workers reported higher levels for the same three areas of knowledge. More education about HIV is needed to prevent its transmission among these immigrants.

When one educates migrants from Russia as a health care professional, questions concerning the following should be included as part of an HIV educational session:

- The region in Russia from which the migrant emigrated
- The migrant's knowledge of HIV/AIDS and any unhealthy sexual activity
- The migrant's social support network

From Amirkhanian, Y. A., Kuznetsova, A. V., Kelly, J. A., Difranceisco, W. J., Musatov, V. B., Avsukevich, N. A., et al. (2010). Male labor migrants in Russia: HIV risk behavior levels, contextual factors, and prevention needs. *Journal of Immigrant Minority Health,* 13, 918–928.

Approximately 10.9% of the world's population, or 795 million of 7.3 billion, are chronically undernourished, and all but 10% of them

are in developing countries (Food and Agriculture Organization of the United Nations et al., 2015). Annually, more than 3 million children die of starvation (Food and Agriculture Organization of the United Nations et al., 2015). Undernutrition heightens the effect of every disease. (Figure 25-1). At the other end of the spectrum, obesity is a rising cause of health problems in both medium- and high-income countries. The number of the world population with obesity more than doubled from 1980 to 2008, and almost 43 million children 5 years or younger were obese in 2008 (WHO, 2012a). Whereas urgent interventions to combat hunger and infectious diseases (such as HIV infection and diarrheal diseases) are needed in many developing countries, behavioral interventions to fight cardiovascular disorders and obesity are crucial in medium-income and high-income countries.

FIGURE 25-1 Lunchtime for schoolchildren in a remote area of Thailand. The food was made possible through donations from health care providers.

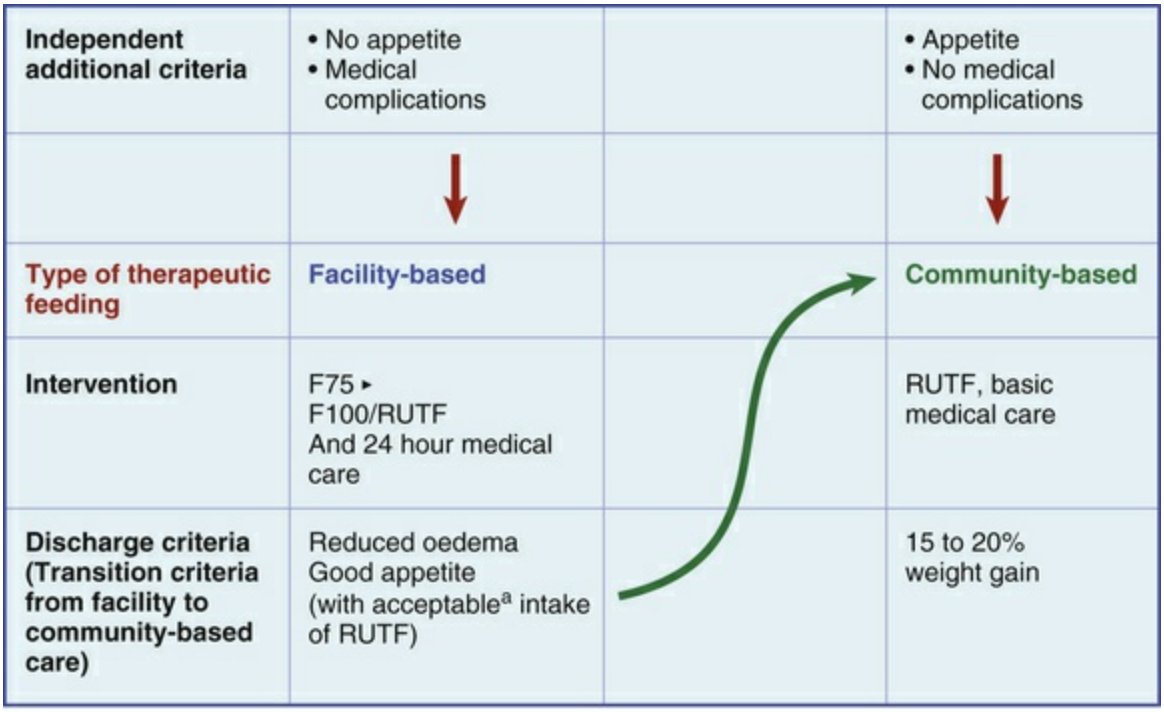
Emerging infections, various forms of intercultural and interpersonal violence, terrorism, and bioterrorism also pose great threats and risks to the world. This chapter presents information on malnutrition, **Ebola virus** disease (EVD), **Zika virus** disease (ZVD), **methicillin-resistant *Staphylococcus aureus*** (MRSA), HIV, and HPV infections, violence, bioterrorism, and terrorism, followed by

discussion of their important implications for the future.

Malnutrition

WHO (2000) defines **malnutrition** as "bad nourishment" that can be associated with "either too much or too little food intake and [is] not limited to the wrong types of food." Malnutrition is characterized by "inadequate or excess intake of protein, energy, and micronutrients such as vitamins." In general, malnutrition can be classified into three categories: protein-energy malnutrition, micronutrient deficiencies, and obesity (WHO, 2000). This chapter will address only protein-energy malnutrition because it is the most serious among the three types (WHO, 2000).

Protein-Energy Malnutrition



Protein-energy malnutrition, a lack of calories and protein, is widespread in low-income countries and is the most lethal form of malnutrition/hunger (World Hunger Education Service, 2012). Humans convert food into energy, and the energy contained in food is measured in calories. Protein is necessary for key body functions, including provision of essential amino acids and development and maintenance of muscles (WHO & United Nations Children's Fund, [UNICEF], 2009). Protein-energy malnutrition can be severely harmful to the mental and physical development of individuals, especially children younger than 5 years (WHO, 2016h). Worldwide, one in two deaths among children younger than 5 years old stem from protein-energy malnutrition (WHO, 2016h). One in four children are underweight, and one in three children are stunted (WHO, 2016h).

Severe Acute Malnutrition

WHO defines severe acute malnutrition as the presence of serious wasting and/or edema (WHO & UNICEF, 2009). Severe wasting is defined as the weight of a child being less than 70% (or less than three standard deviations) of the median weight for height (WHO, 2011) and/or having a mid-upper arm circumference less than 115 mm—a

new cutoff (WHO & UNICEF, 2009). Children with severe acute malnutrition require immediate treatment because they have a higher risk of death than children without severe acute malnutrition (WHO & UNICEF, 2009). Severe wasting is caused by loss of subcutaneous fat and skeletal muscle and is highly noticeable because of underdeveloped buttocks, thighs, and upper arms. It is also characterized by sunken eyes, visible ribs, and protruding shoulder blades (WHO, 2004). Children with severe wasting usually have a distended abdomen and a general overall appearance in some way similar to that of an older adult. In general, these children are irritable, anxious, and cry easily; yet they will often have an absence of tears while crying because of lacrimal gland atrophy (WHO, 2004).

Treating children with severe acute malnutrition involves providing special therapeutic, milk-based foods called ready-to-use therapeutic foods (RUTFs), which are soft, crushable, and tasty, nutrient- and energy-rich foods that can be consumed by children 6 months of age or older (WHO & UNICEF, 2009). When a child has a good appetite with no medical conditions (e.g., hypoglycemia, hypothermia, dehydration, electrolyte imbalance, and/or infections), use of RUTFs under community-based care is appropriate. However, when a child does not have an appetite and/or medical conditions are present, the child needs to receive facility-based care (WHO & UNICEF, 2009). The child may be transferred from a facility-based care setting to a community-based setting when the following conditions are met: the child does not have bilateral edema, regains a good appetite, and eats at least 75% of his/her calculated RUTF ration for the day (WHO & UNICEF, 2009). The child can be discharged from a community-based care setting when he or she has a weight gain of 15% since admission (WHO & UNICEF, 2009) (Figure 25-2).

[a]Child eats at least 75% of their calculated RUTF ration for the day

FIGURE 25-2 Severe acute malnutrition management. *RUTF*, Ready-to-use therapeutic food. (Reprinted with permission from World Health Organization. [2011]. The WHO child growth standards. http://www.who.int/childgrowth/standards/en/.)

Addressing Malnutrition at the Global Level

The Centers for Disease Control and Prevention (CDC), the **World Health Organization (WHO)**, and UNICEF have worked collaboratively to create several initiatives to address the malnutrition issue. These include the Baby Friendly Hospital Initiative programs to manage nutrition needs during emergencies, global nutrition data banks, a global network of collaborating centers in nutrition (UNICEF, 2012), and the International Micronutrient Malnutrition Prevention and Control (IMMPaCt) program (CDC, 2012a).

The Baby Friendly Hospital Initiative, launched in 1991 by UNICEF and WHO, has as its goal to promote exclusive breastfeeding during the first 4 months of life when it is most required by the infant (UNICEF, 2012). The program involves at least 170 countries and more than 16,000 hospitals (UNICEF, 2012). Through the initiative a mother

starts breastfeeding as soon as her child is born and continues to breastfeed her child exclusively, unless medically otherwise indicated or until the child is 4 months old. This includes avoiding supplemental food and drink until the older child is ready for such intake (UNICEF, 2012).

The IMMPaCt program, established in 2000 by the CDC, works with global partners such as WHO, UNICEF, and the US Agency for International Development to provide its skills and resources to eradicate vitamin and mineral deficiencies around the globe (CDC, 2012a). The IMMPaCt program's activities include conducting surveys; providing micronutrients to infants, young children, and women of childbearing age; and monitoring and evaluating intervention systems (CDC, 2012a). Since its establishment, the IMMPaCt program has provided assistance and/or training in more than 70 countries around the world.

Emerging Infections

Ebola Virus Disease

EVD (originally known as Ebola hemorrhagic fever) emerged on to the world scene of deadly infections in the mid-1970s in the African countries of the Democratic Republic of Congo and what is now known as South Sudan. The most recent major outbreak occurred in three countries in West Africa: Guinea, Sierra Leone, and Liberia. Case-fatality rates for EVD average approximately 50%, with deaths in some outbreaks as high as 90%. The virus spreads by human-to-human contact from an index case infected by contaminated blood, secretions, or bodily organs of a wild animal such as a fruit bat or monkey. Humans can be infected by contact with bedding and clothing of an infected person (CDC, 2016a; WHO, 2016a). The risk of transmission by sexual contact is an important concern, and research is ongoing (Fischer & Wohl, 2016). Current recommendations include abstinence from sexual intercourse for 3 months after development of symptoms or use of condoms if abstinence is not feasible (Rogstad & Tunbridge, 2015).

Currently there are no vaccines available to protect people from Ebola virus; therefore community involvement is vital for the prevention and control of an outbreak. Control measures include careful case management, contact tracing, a viable laboratory service, safe internment of deceased persons, and risk reduction for spread of the virus. See the section entitled "Prevention and control" in WHO (2016a) for details on these measures. Cultural practices differ greatly from country to country, region to region, and even village to village. The diversity of cultures must be taken into consideration when one is expecting a public health response (Alexander et al., 2015). Burial practices, bushmeat consumption, use of traditional medicines, beliefs about modern medicine and health care interventions, and stigmatization of Ebola survivors are topics to include (Alexander et al., 2015). Ways to modify practices particularly related to the preparation of a dead body for burial must be found to curtail the

spread of Ebola virus. This must be done in conjunction with an understanding of other nonpharmaceutical interventions (Pandey et al., 2014).

The prevention of the spread of infection in the health care setting must start with standard precautions when any patient is being cared for: basic hand hygiene, personal protective equipment, and respiratory hygiene. If EVD is suspected, health care workers must add extra protective measures to avoid contact with all bodily fluids and contaminated surfaces during direct patient care (Lupton, 2015; Marion et al., 2016). Protective clothing must include a face shield of some type, long-sleeved gown, and gloves. Laboratory workers must follow strict protection protocols. In the community, safe burial practices using the same techniques health care workers have instituted are essential.

Follow-up of EVD survivors is important for surveillance and treatment of long-term complications. Tiffany and colleagues (2016) found that 57% of EVD survivors followed up in Sierra Leone developed ocular complications. Others complications included arthralgia, fatigue, headaches, abdominal pains, and anemia. Even more difficult for survivors is the stigmatization they experience when discharged from the hospital. In a study of 81 EVD survivors in Sierra Leone (Nanyonga et al., 2016), 96% reported being rejected by their communities, leading to fear and anxiety about returning home. Economic hardships accompanied the physical and psychosocial sequelae. A full range of services are needed to care for these survivors.

Zika Virus Disease

ZVD burst onto the global scene in 2015 with reports of hundreds of children in Brazil born with microcephaly to mothers who had been ill because of this virus. Zika virus was actually identified in the 1940s. The main vector is *Aedes* mosquitos known to live in Africa, the Americas, Asia, and the Pacific. Classic transmission is from the bite of an infected mosquito to a human. It is also now known that Zika virus can be transmitted from men who are infected with the virus during

sexual contact. As the virus can stay in semen longer than it can in blood, the virus can be transmitted before a man develops symptoms, during the symptom phase, and even after symptoms have disappeared. Though transmission of Zika virus from male to female sexual partners in more likely (Coelho et al., 2016), reports confirm that female to male transmission is also possible (CDC, 2016c). For couples in which the woman could get pregnant, a condom should be used during every sexual contact or the couple should abstain from sexual relations to prevent infection with Zika virus for at least 6 months after symptoms appeared. If there were no symptoms but the man has traveled to a Zika virus–infested region, the couple should use a condom or abstain from sex for 8 weeks after the man returns (CDC, 2016c,d).

Most people infected with Zika virus will not exhibit symptoms. If symptoms appear, they are usually mild and can last up to 1 week. The symptoms include fever, joint and muscle pain, headache, and a rash. The virus can be detected by laboratory testing confirming its presence in blood, urine, and/or saliva. The incubation period is not yet well established but is believed to be a few days from bite to symptoms.

In 2015, public health officials in Brazil observed an increase in the number of patients with Guillain-Barré syndrome and an increase in the number of babies born with microcephaly at the same time as there was an increase in the number of cases of ZVD. Research is under way to investigate whether Zika virus is the cause of these apparent complications or if there is another reason.

Prevention of ZVD requires elimination of mosquitos' breeding sources and reduction in opportunities for mosquitos to bite people. Any objects that can contain and hold water should be removed or cleaned: pots, tires, buckets, gutters, etc. People should cover their skin as much as possible, screen windows and doors, sleep under mosquito nets, and use insect repellant (WHO, 2016b). No vaccine against the virus exists.

The CDC provides numerous tools, in PDF documents, on its website for health care providers to use when they are caring for

patients who may have or who have contracted Zika virus. These tools include testing algorithms for pregnant women who have traveled to regions of the world known to have Zika virus, for pregnant women who live in these same regions, and for infants whose mothers reside in or traveled to Zika virus–infested areas of the world. Other tools include one to measure an infant's head circumference, fact sheets on testing for the virus, and preconception counseling (CDC, 2016b). There is also a page on the CDC website with details about a US Zika Pregnancy Registry. This page includes links to fact sheets for health care providers in general, one specific to pediatric health care providers, and one for pregnant women (CDC, 2016o). Interim guidelines are also available on this website.

Human Papilloma Virus Infection

Human papilloma virus (HPV) is a group of approximately 150 related viruses, each with an assigned number. HPV is named for the warts it causes called papillomas. Almost 80 million people in the United States are infected with HPV, the most common sexually transmitted infection (CDC, 2016n). HPV is transmitted by intimate vaginal, anal, or oral contacts, even if the person is asymptomatic. Most HPV infections are asymptomatic and disappear without causing any problems; persistent ones, however, may lead to precancerous lesions, progressing years later to cervical cancer. HPV infections occur in men and women. Most HPV infections are acquired shortly after a person becomes sexually active with a person or persons infected with the virus. Abstinence, delay in becoming sexually active, use of condoms, limits on the number of sexual partners, and vaccination against HPV should slow down the increase in the number of people who carry and propagate HPV (WHO, 2015c).

Vaccination

WHO 2014 guidelines included the following elements: vaccination of all girls aged 9 to 13 years with two doses of the HPV vaccine; screen

women with HPV tests; and promote screening to a larger audience (WHO, 2014). Men should be included in any screening awareness efforts because without their support women in many cultures will not participate in screening practices (Learmonth et al., 2015; Lim & Ojo, 2016; Modibbo et al., 2016; William et al., 2014).

The HPV vaccine was introduced in 2006. The current FDA-approved vaccines against HPV are Gardasil, Cervarix, and Gardasil 9 (White et al., 2016). National vaccination programs have been conducted in Rwanda, Uganda, and Uzbekistan, to name a few countries (GAVI Alliance, 2014). The prevalence of vaccine-type HPV infections is decreasing in US vaccinated girls (Dunne et al., 2015). The Advisory Committee on Immunization Practices, the American Academy of Pediatrics, and the American Cancer Society recommend that sexually active young men be vaccinated against HPV, starting at the age of 11 years (White et al., 2016). Barriers to HPV vaccination include social norms related to sexual activity, financial constraints, and levels of trust or distrust in vaccination programs (Ferrer et al., 2014). Some parents expressed concern that vaccination would encourage young people to be sexually active (Griebeler et al., 2012).

Human Papilloma Virus and Cervical Cancer

HPV triggers a sexually acquired infection that may lead to cervical cancer. Cervical cancer is one of the world's deadliest, but preventable, forms of cancer. There are more than 500,000 new cases each year (International Agency for Research on Cancer, 2013; WHO, 2015c). Approximately 85% of the approximately 270,000 annual deaths occur in the developing world. Cervical cancer incidence rates in sub-Saharan Africa are the highest in the world (De Vuyst et al., 2013). The risk factors for persistent HPV infection and progression to cervical cancer include early first sexual intercourse, multiple sexual partners, and a compromised immune system (WHO, 2015c). Lack of access to effective screening and to services that promote early detection and treatment may explain the dramatic differences in prevalence.

Screening and Testing

Screening recommendations in the United States are set by the American Cancer Society, the American College of Obstetricians & Gynecologists, and the US Preventive Services Task Force. The current recommendations for routine cervical screening are as follows (CDC, 2015b): start at age 21 years and continue through to age 65 years; conventional or liquid-based cytological tests (Papanicolaou test) for women younger than 30 years; for women 30 years or older, include oncogenic or high-risk HPV tests; every 3 years for women 21 to 29 years of age perform a Pap test; for women aged 30 to 65 years, perform co-testing; if the results of both tests are negative, screening is not recommended again for 5 years; the testing recommendations are the same for women regardless of whether they have been vaccinated against HPV or not; refer women with abnormal test results to an appropriate provider for follow-up. Barriers to cervical screening include fear of diagnosis, lack of access, lack of spousal support, lack of finances, cultural modesty (only wanting a female provider), not knowing about cervical cancer, and not seeing self as having risk factors (Compaore et al., 2015; Lim & Ojo, 2016). A promising screening test is careHPV (Bansil et al., 2014; Jeronimo et al., 2014).

Health care professionals have an important role to play in the promotion of vaccinations against HPV and screening for HPV and cervical cancer. Studies have noted that when health care providers, particularly nurses, educate women and recommend the vaccine, immunization rates increase (Lau et al., 2012). Fact sheets, continuing education courses, and vaccination schedules and recommendations for use by health care providers in combating HPV infections and subsequent cancer risks can be found on the CDC website (CDC, 2016n).

Methicillin-Resistant *Staphylococcus aureus* Infection

Colonization of *S. aureus* in the nasal area is common and asymptomatic in one in three healthy individuals (CDC, 2011;

Perencevich & Diekema, 2010). On the other hand, MRSA, a form of staphylococcus bacteria that causes skin/soft tissue infections, is estimated to be colonized in only 1% of healthy individuals (CDC, 2011). It is resistant to β-lactams (e.g., methicillin, oxacillin, penicillin, and amoxicillin) (CDC, 2012b).

Health care–associated MRSA (HA-MRSA) infection may occur in hospitalized individuals who undergo medical or surgical procedures, such as administration of ventilation apparatus or introduction of a nasogastric tube or catheter (particularly in those with minimized immune functions), and can lead to life-threatening infections, such as pneumonia and bacteremia. However, a study that reviewed 82% of all MRSA cases in the United States from 2005 through 2008 showed that life-threatening HA-MRSA infections dropped by 28% (Kallen et al., 2010). Factors related to the decline were not reported.

In the community setting, community-associated MRSA (CA-MRSA) strains have emerged as serious threats in the past 2 decades and can cause dermatitis and soft tissue infections (CDC, 2010, 2012b), with the ability to also cause fatal infections in the lungs (e.g., necrotizing pneumonia, purpura fulminans, and postviral toxic shock syndrome) (Schlievert et al., 2010). Most CA-MRSA cases are mild and include a skin or soft tissue infection (i.e., a boil or abscess). Usually, the infected area resembles a red, swollen, and painful "spider bite" (CDC, 2010). Pus or other drainage may be present. If the infection is limited to the skin, it can be difficult to distinguish CA-MRSA from HA-MRSA (CDC, 2010).

Among severely CA-MRSA-infected people, complications may include serious necrotizing infection, septicemia, pneumonia, and death (CDC, 2010).

CA-MRSA cases have been reported by emergency departments, day care centers, schools, correctional facilities, sports facilities, dormitories, and military stations (CDC, 2011; Sedighi et al., 2011). People who are generally healthy can contract the bacteria through close skin-to-skin contact, cuts in or abrasions of the skin, crowded conditions, shared utilities (e.g., clothing items and towels), and poor hygiene (CDC, 2011; Kirkland & Adams, 2008). In addition, those who

are taking or have previously received antibiotic therapy have a greater risk of infections than those who do not have a history of antibiotic intake (Fekete, 2007).

The most up-to-date clinical guidelines for CA-MRSA management were published in 2011 by Liu and colleagues (2011). The guidelines suggest that CA-MRSA skin infections, such as boils or abscesses, may be treated by incision and drainage. Antibiotic regimens guided by sensitivity test results should be administered to infected individuals. Intravenous antibiotic treatment should be considered among hospitalized individuals who show signs of oral therapy nonadherence. Oral antibiotics may include sulfamethoxazole-trimethoprim, clindamycin, doxycycline, minocycline, and linezolid.

Knowledge of this disease is essential to enable health care professionals to initiate appropriate infection control. In general, CA-MRSA spreads more easily, has higher recurrence rates, and causes more skin problems and serious damage than the traditional HA-MRSA found in hospital settings (CDC, 2012b). Standard precautions —a combination and expansion of universal precautions and body substance isolation—are required among health care professionals to prevent cross-contamination (CDC, 2011). Meticulous hand washing has been found to be important and is recommended as a cost-effective everyday practice; see CDC (2006) for more details. Current recommendations by the CDC for various sectors of the community are on the CDC website at http://www.cdc.gov/mrsa/community/index.html.

Human Immunodeficiency Virus/Acquired Immunodeficiency Syndrome

Approximately 36 million people worldwide are infected with HIV, with 25 million in sub-Saharan Africa, 3.9 million in South/Southeast Asia, 1.5 million in Latin America, 1.3 million in eastern Europe and Central Asia, 1.3 million in North America, 860,000 in western/central Europe, 880,000 in East Asia, 260,000 in the Middle East/North Africa, 250,000 in the Caribbean, and 51,000 in Oceania (UNAIDS, 2017).

Although the number of newly infected people continues to decline each year, approximately 2.5 million people were infected in 2012. During the same year, there were 1.6 million AIDS-related deaths (CDC, 2016p). Overall, the number of people living with HIV reflects the fact that people receiving antiretroviral therapies are living longer (CDC, 2016p).

In some low-income countries, HIV prevalence rates in the adult population are higher than those in high-income countries. For instance, the 2014 rate was 27.73% in Swaziland and 25.16% in Botswana (CIA, 2015b). The rate is approximately 0.18% in Sweden and 0.33% in the United Kingdom (CIA, 2015b). Although economic level is sometimes negatively associated with HIV rates, evidence also shows that cultural beliefs and practices are significant factors contributing to HIV infections.

The modes of HIV transmission include sexual contact with persons of the opposite sex, sexual contact with persons of the same sex, from mother to baby at birth or through breast milk, contact with objects contaminated with HIV such as needles, syringes, and knives, and through blood transfusions of HIV-infected blood. In east and southern Africa, 60% to 95% of the new infections are occurring among the heterosexual population, people with multiple sex partners, their usual partners, and couples in a mutually faithful discordant relationship. (*Discordant relationship* in this context is defined as one partner infected with HIV and the other partner HIV negative.) In Caribbean and Latin American countries, the largest group of new infections is in men who have sex with men, although there are sizeable new infections also among sex workers and their clientele, and in the general heterosexual population. In Eastern Europe, newly infected individuals are mostly those who are intravenous drug users and their sexual partners. In Asia, male risk behaviors dominate the transmission methods (Gouws & Guchi, 2015).

Clearly, the challenges of reducing HIV/AIDS rates are complex and the solutions require multidisciplinary and multidimensional approaches. Ordinary people, community leaders, health care

professionals, and organizations at all levels must work collaboratively. Together, we can consider gender/social inequalities and cultural/religious beliefs and practices as we work to identify barriers to understanding and facilitate the reduction of HIV infections (Box 25-2). Support from all parties will enable us to set priorities and fight HIV/AIDS more effectively at the global level. UNAIDS (2011) is working collaboratively with its partner organizations, such as UNICEF, UNESCO, WHO, and the World Bank. The ambitious visions of UNAIDS include zero new HIV infections, zero AIDS-related deaths, and zero discrimination; the commitment is that everyone globally should have universal access to HIV prevention, treatment, care, and support (UNAIDS, 2011). To reach these optimal goals, UNAIDS has outlined three strategic directions: revolutionizing HIV prevention; catalyzing the next generation for treatment, care, and support; and advancing human rights and gender equality in responses to HIV (UNAIDS, 2011).

Box 25-2

Ethical Dilemmas

- Is it ethical in a clinical trial not to give HIV-positive persons in the control group the most recent antiretroviral drugs?

- Is it ethical to prosecute a local man who lives in Africa and wants to cure his HIV infection by having sex with a young virgin?

Revolutionizing HIV prevention means that the focus is shifted from HIV rates of "prevalence" to "incidence" (UNAIDS, 2011). "Incidence" deals with the number of new HIV infections in a particular population during a certain period, whereas HIV "prevalence" is the percentage of all cases (new and old) of HIV infections at a certain time point (AVERT, 2012). In this focus, hot spot transmissions need to be identified, and empowerment (especially among young people) needs to be encouraged so that all people involved will adopt more proactive behaviors to decrease the number

of new HIV infections. UNAIDS (2011) has announced its support of political change in terms of HIV, new approaches to technology, the reduction of stigma and discrimination associated with HIV, and comprehensive sex education for HIV-positive individuals, networks, and related key populations.

Catalyzing the next generation of treatment, care, and support involves universal access to antiretroviral treatment for all HIV-positive individuals who need medication (Box 25-3: Research for Evidence-Based Practice). UNAIDS (2011) expects that all HIV-positive individuals and their families will have access to essential care and support. UNAIDS (2011) will act with each nation to make it possible that simpler, more effective, and more affordable therapy will be universally accessible so that HIV deaths related to tuberculosis infection will be minimized.

Box 25-3

Research for Evidence-Based Practice

Atazanavir boosted with ritonavir has been found to be an effective once-daily antiretroviral medication for HIV-positive adults. However, because atazanavir is expensive, an original prospective study was conducted among 84 Thai adults to examine if the effectiveness of atazanavir would be maintained when the dosage was lowered from 300/100 mg once daily to 200/100 mg once daily. The participants were followed up for more than 60 weeks, and adequate atazanavir plasma concentrations were found. Moreover, CD4 counts increased over time, with no change in cholesterol, triglyceride, LDL, or HDL levels, whereas bilirubin levels decreased over time. These results suggested that a lower dose of atazanavir is effective and economical. A subsequent study of 127 Asian HIV-infected patients who received the same dosage for up to 6 years indicated that this dosage achieved high viral suppression for up to 4 years. In resource diminished settings, low-dose atazanavir plus ritonavir is highly beneficial because it decreases both toxicities and cost, allowing greater population access to limited supplies of the

drug.

From Avihingsanon, A., Apornpong, R., Kerr, S. J., Ananworanich, J., & Ruxrungtham, K. (2010). Long-term efficacy and safety of low-dose ritonavir-boosted atazanavir (ATV/r) 200/100 mg in HIV-infected Thai patients. *Journal of International AIDS Society, 13*(Suppl 4), P60; Avihingsanon, A., Apornpong, T., Kerr, S.J., Make-a-nantawat, W., Thammajaruk, N., Phonphithak, S., et al. (2015). Low-dose ritonavir-boosted atazanavir (200/100 mg) maintained a high virological efficacy up to 4 years in treatment-experienced HIV-1 infected adults: A prospective cohort study from Asia. *Journal of AIDS & Clinical Research*, 6, 460. doi:10.4172/2155-66113.1000460.

Advancing human rights and gender equality for the HIV response means working toward the day when gender inequality, violence against women and girls, and stigmatization and discrimination related to HIV will be eradicated (UNAIDS, 2011). Punitive laws and practices against HIV-positive individuals need to be eliminated. UNAIDS (2011) will work with each government to reinforce the rights of HIV-positive individuals and to better educate infected individuals about their rights. UNAIDS proposes to accelerate the full implementation of these goals within countries by building synergies with communities and other organizations.

Nongovernmental Organizations

UNAIDS has recognized the importance of the inclusion of nongovernmental organizations (NGOs) in the worldwide fight against the spread of HIV/AIDS. The UNAIDS Programme Coordinating Board has as its nonvoting members representatives from three NGOs from developing countries and two NGOs from developed countries. “The NGO representatives actively seek input from their respective communities on key issues related to UNAIDS policies and programs, and advocate with Members States (governments) and Cosponsoring organizations (the ten United Nations organizations that make up the UNAIDS Joint Programme) for meaningful improvements in the implementation and evaluation of AIDS policies and programmes” (UNAIDS, 2007).

Violence

Violence can happen to individuals anywhere, regardless of gender, age, or nationality, and is among the leading causes of physical, sexual, reproductive, and mental health problems worldwide. Each year, violence has been estimated to cause the loss of 1.6 million lives globally. In addition, violence costs nations immeasurable amounts of money in terms of health care, law enforcement, and loss of productivity. The cost of violence containment to the world economy was approximately US$9.46 trillion in 2012 (Dickenson-Jones et al., 2014).

Definition of Violence

Violence is defined differently in different parts of the world, depending on people's beliefs and cultures. The definition proposed by WHO is used in this chapter. According to WHO (2012b), violence is defined as "intentional use of physical force or power, threatened or actual, against oneself, another person, or against a group or community, that either results in or has a high likelihood of resulting in injury, death, psychological harm, maldevelopment or deprivation."

In response to violence, WHO has proposed the four-step public health approach that includes the following steps: defining the problem; identifying risks and protective factors; devising and testing means of dealing with violence; and applying successful means on a large scale (CDC, 2012c). Successful response prevention of violence should be based on rigorous research and collaboration among health care professionals and other experts in areas such as epidemiology, criminology, education, and economics.

The CDC is an example of an organization in the United States that is applying the preceding four-step public health model. Activities, projects, and funding supported by the CDC are outlined in the following sections as an exemplar.

Defining the Problem

To understand the magnitude of violence in the United States, different data sources are needed. Such sources may include police reports, medical examiner files, vital records, medical records, population-based surveys, and research results. Extrapolation of the data from these sources can help us to learn about violence frequencies, places, trends, and perpetrators. The CDC has provided funding to studies deemed to be helpful in defining violence problems. The National Violent Death Reporting System is an example of a project funded by the CDC to ensure that timely, complete, and accurate data are collected about violent deaths for different states in the United States. It is hoped that the data will enable each state to gain a clearer picture of violence so as to respond more effectively (CDC, 2012b).

Identifying Risk and Protective Factors

A "risk factor" is defined as "a characteristic that increases the likelihood of a person becoming a victim or perpetrator of violence," and a "protective factor" is defined as "a characteristic that decreases the likelihood of a person becoming a victim or perpetrator of violence" (CDC, 2015a). Knowing risk and protective factors can help responsible organizations and personnel to estimate violence magnitudes and devise appropriate prevention measures. It is important to note that the identification of risk factors should be used not to blame victims of violence but rather as a focus for intervention.

Devising and Testing Means for Dealing With Violence

In this step, data on violence from all available sources are extrapolated and assessed. On the basis of the evidence, programs and interventions are planned. Such programs and interventions are then implemented, tested, and rigorously evaluated to determine their effectiveness. An example of step 3 activities is the Choose Respect

project—a communication initiative for sixth grade to eighth grade students to guide adolescents in forming healthy relationships so as to prevent dating violence (CDC, 2012b). Technology also plays a role in protecting violence victims. The MyPlan app is a web-based safety planning tool that helps violence victims to respond to dating violence. It enhances victims' decisional conflict and safety behavior (Glass et al., 2015).

Applying Successful Means on a Large Scale

After a program has been tested successfully for its effectiveness, large-scale dissemination should occur. At this stage, communities are encouraged to adopt a program tailored to their own problems and needs. The program should be evaluated in each community. Training, networking, technical assistance, and process evaluations are to be supported by all parties involved. An example of step 4 activities initiated by the CDC is the National Youth Violence Prevention Resource Center with its goal to prevent youth violence and suicide. In this project, a website, toll-free hotline, and fax-on-demand service were created as helpful resources for youth. Any interested community can request more information from the CDC.

Forms and Context of Violence

WHO (2016c) classifies violence into three major categories: interpersonal, self-directed, and collective.

Interpersonal Violence

Interpersonal violence (IPV) is violence committed by an individual or a small group of people in a wide range of acts and behaviors (emotional, physical, sexual, and psychological). The violence could happen to people of any age (adolescents, children, and older adults). It could also occur anywhere, including the home, workplace, neighborhood, and unfamiliar places.

Whereas violence in the community (e.g., youth violence or crimes)

is highly visible, violence in the home is usually hidden. The impact of such hidden violence is complicated by the fact that authorities or health personnel are less willing or prepared to deal with it (Koistinen & Holma, 2015).

The risk factors for IPV include a victim's low self-esteem, low self-control, and personality/conduct disorders (CDC, 2015a). Other risk factors are reported to be lack of social support, dysfunctional family structure, family history of violence, and drug and alcohol abuse (Ross et al., 2015; Sullivan, 2013). Alcohol intoxication may increase violent actions by impairing the drinker's cognitive functions and processes through alterations of social cue perceptions and inhibitions (Bernardin et al., 2014). According to the Department of Justice, 37% of convicted offenders were drinking at the time of their arrest (National Council on Alcoholism and Drug Dependence, 2015).

In addition, four subtypes of male perpetrators are reported as the mentally ill, undercontrolled/dysregulated, chronic batterer, and overcontrolled/catathymic subtypes (Koistinen & Holma, 2015). Shared characteristics were found among the four subtypes of male perpetrators. For example, most of them were abused as children, tend to be in their mid-30s to late 30s, and tend to show pathology (Koistinen & Holma, 2015).

Mothers who are victims of violence along with their children who witness such violence are at risk of physical, emotional, psychological, and developmental damage (McFarlane et al., 2014). A study in New York revealed that IPV is a primary cause for seeking treatment at the emergency department because of the different injuries (Gilbert et al., 2012). In the Latino population, help-seeking action is increased among children who witness IPV episodes as they call 911 for help (Falconier et al., 2013).

Culture and gender inequality are also significant factors in IPV. Evidence shows that women in countries where gender equality is emphasized experience violence less than those in countries with gender inequality (Fulu et al., 2013). Fulu and colleagues (2013) reported that that the highest rate of physical and/or sexual violence among women was in Papua New Guinea (80.0%), whereas a rate of

25% was reported in Indonesia.

A study among 245 women in Thailand revealed that the rate of emotional abuse was 88.2%, that of physical abuse was 59.2%, and that of sexual abuse was 23.9% (Ross et al., 2015). Predictors of emotional abuse included partner's drug use and gambling behavior. The predictor of physical abuse was drug abuse. No predictor was found for sexual abuse. Violence in this study was found to be associated with depression and physical problems (Ross et al., 2015). This result aligns with a study that summarizes the literature concerning history of childhood sexual abuse and depression or depressive symptoms among pregnant and postpartum women, which revealed that women who were abused reported higher rates of postpartum depression than those who did not experience abuse (Wosu et al., 2015). Social support was found to mediate the effects of IPV on depression and physical health in the Thai study (Ross et al., 2015).

It is important for health care providers to understand the seriously negative impact that IPV can have on individuals. They should be able to identify such violence and be aware of helpful resources for people affected by violence, as well as their children. Local domestic violence crisis contact information (i.e., numbers and counseling services) should be readily provided to these people. A sexual violence assessment and care guide as proposed by Ross and colleagues (2009) is a helpful resource for health care professionals who work with female care recipients, especially for those who feel uncomfortable mentioning the subject (Ross et al., 2010). This tool has been used successfully by community health nurses in Thailand (Sawangchareon et al., 2013).

Self-Directed Violence

Self-directed violence is defined by WHO (2016c) as "violence in which the perpetrator and the victim are the same individual and is subdivided into **self-abuse** and **suicide**." It is estimated that almost 1 million individuals die by suicide annually (a person commits suicide every 40 seconds) (WHO, 2012d). Previously, suicide rates had been

highest among the male older adult. However, the rates among young people aged 15 to 24 years have been increasing to such an extent that suicide is the second leading cause of death in this age group in some developed and developing countries (WHO, 2012d). Although the major factors contributing to suicide in Europe and North America include mental disorders, especially depression, and alcohol use disorders, impulsiveness is found to be a major factor in Asian countries (WHO, 2012c).

WHO (2012c) recommends that effective suicide prevention interventions should include restriction of access to common methods of suicide where possible or when prudent, along with effective prevention and treatment of depression and alcohol and substance abuse. However, there are clearly challenges to such interventions. In many countries, for example, a lack of awareness about suicide and the taboo to discuss suicide openly exist. Many countries will need to initiate training for prevention of suicide, including appropriate certification for health care personnel, and to seek the involvement of individuals from sectors other than health care, including education, labor, law, politics, police, justice, religion, and the media.

Collective Violence

Collective violence is defined as the instrumental use of violence by a particular group of people for specific political, economic, or social objectives. Such violence may include armed conflicts within or between states or nations, genocide, terrorism, repression, and other abuses of human rights (WHO, 2012d) (Figure 25-3).

FIGURE 25-3 Armed conflicts can be within or between states and nations.

In the 20th century, it is estimated that 191 million people lost their lives as a result of armed conflict. More than half of these people were civilians. In 2000, more than 300,000 people died because of collective violence. Most victims lived in the poorer regions of the world (WHO, 2012d). Besides death, the aftermath of collective violence includes physical and psychological disabilities that exert burdens on families, communities, and nations. Young children and refugees are usually among the most vulnerable to the aftermaths of disease and posttraumatic stress disorders (PTSDs) related to violence (WHO, 2012b).

WHO (2012b) is committed to working with its partners at the regional, national, and international levels to prevent collective violence. Its goal is to identify and implement preventive strategies. Data collection systems are used to support and evaluate the success of the strategies. In this effort, political commitment and momentum are required from a wide variety of concerned parties to strengthen and increase violence prevention endeavors in the next 5 years (WHO, 2012b).

Terrorism

The threat of **terrorism**—whether homegrown or international—creates a unique brand of fear among individuals and communities within our increasingly interconnected global cultures (Braithwaite, 2013). Moreover, the need to be able to respond to terrorism—potential or actual—poses important challenges to health care professionals and community planners at all levels of our society (Figure 25-4). The International Council for Nurses describes its position on the role of nursing concerning disaster preparedness to include risk assessment as well as management strategies bridging multiple disciplines and system levels.

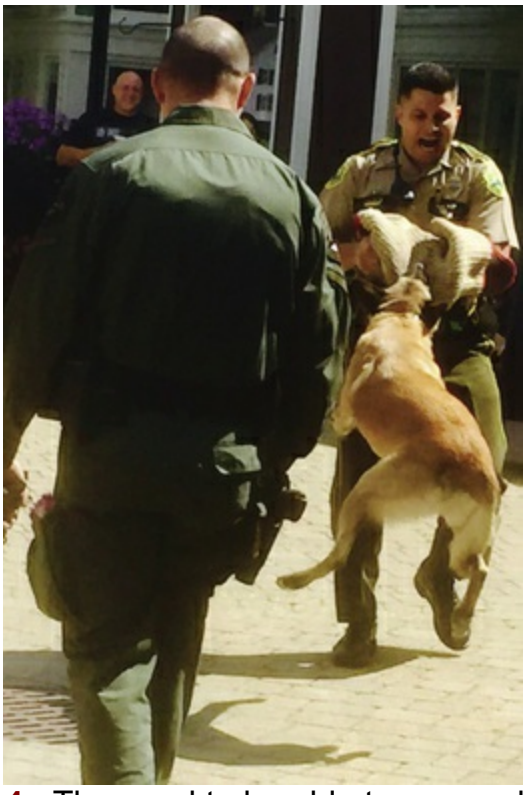


FIGURE 25-4 The need to be able to respond to terrorism poses important challenges to all.

Nursing plays a key role in responding to the short-, medium-, and

long-term requirements of populations stricken by disaster. The establishment of a set of tailor-made disaster nursing core competencies for the community and the development of a comprehensive curriculum for public health will help nurses plan for and streamline health care responses to such mass events internationally (Loke & Fung, 2014). Much work in laying the foundations for such a broader, more global preparedness has already been started.

Research on the surgical responses to the 2008 terrorist attacks in Mumbai, India, reveals the importance of an initial disaster management plan to treat casualties. The earliest victims of firearm and blast trauma were received in a primary triage zone and then sent to different stations for further treatment. The study concluded that onsite triage—established as soon as a site is found to be safe—optimizes the treatment of bullet and blast injuries (Bhandarwar et al., 2012). Another study examined the effectiveness of including a pediatric trauma center (PTC) in responding to victims of a disaster surge. This study added a hypothetical PTC to the response of the Israeli Defense Forces field hospital to the Haiti earthquake in 2010 and measured its effectiveness mathematically, concluding that "aggressive inclusion of PTCs in planning for disasters by public health agencies" (Barthel et al., 2011) can significantly increase overall rates of admission and greatly reduce treatment times (Barthel et al., 2011). Regarding the responses of health care providers to the repercussions of mass disasters, the results from the literature are sometimes conflicting. In the United Sates, studies among victims of the World Trade Center disaster in terms of PTSD suggest that early and brief interventions at the work site were most effective in responding to PTSD, and that informal support from family, friends, and spiritual communities was also beneficial. Conversely, more extensive postdisaster psychotherapy was not found to be beneficial and sometimes led to worse outcomes (Boscarino & Adams, 2008). Mental resilience following the World Trade Center disaster tended to be linked with victims who had higher self-esteem and more social support, whereas victims who experienced "delayed" PTSD following

the attacks tended to be "non-native born, or to have recently experienced lower self-esteem and/or negative life events" (Boscarino, 2011). In Thailand, cognitive-behavioral therapy as a means to treat PTSD was studied in a randomized controlled effectiveness trial. The researchers found that cognitive-behavioral therapy can successfully treat PTSD, even "in settings where very regular [terrorist] attacks are made upon communities in which the patient lives" (Bryant et al., 2011).

Among its overarching influences, one must also weigh terrorism's negative consequences for economies around the world. These include changes in "variables such as Gross Domestic Product (GDP), unemployment, foreign direct investment (FDI), and the tourism industry" (Waxman, 2011). Such economic changes affect the lives of everyday people and, in turn, their health. The threat of terrorism is thus real, and its actual and potential negative effects are pervasive and far-reaching, spanning cultures and ranging from the concrete and immediate to the psychosocial and lasting. Nurses and health care professionals must be among the front lines of response.

Bioterrorism

A bioterrorism attack is the deliberate release of viruses, bacteria, or other germs (agents) used to cause illness or death in people, animals, or plants. These agents are typically found in nature, but it is possible that they could be changed to increase their ability to cause disease, make them resistant to current medicines, or to increase their ability to be spread into the environment. Biological agents can be spread through the air, through water, or in food. Terrorists may use biological agents because they can be extremely difficult to detect and do not cause illness for several hours to several days. Some bioterrorism agents, like the smallpox virus, can be spread from person to person and some, like anthrax, cannot.

(CDC, 2016e)

The preceding definition reflects what many people in different nations may feel or know about **bioterrorism**. As health care professionals, we are required to be knowledgeable about possible diseases/agents that could be used for bioterrorism and the proper responses we should make to an act of bioterrorism.

Bioterrorism is classified by the CDC (2016e) into three different categories: A, B, and C. These categories are based on the ease with which the disease or agent might be spread; the potential negative impact it could have on public health; the extent to which it could cause public panic or social disruption; and the degree to which it would require the public to prepare for an attack.

Category A Diseases/Agents

Category A diseases/agents include various biological agents and pathogens that are not usually seen in the United States and pose the highest risks and have the highest priority. They include anthrax, **botulism, plague**, smallpox, tularemia, and viral hemorrhagic fevers.

Anthrax *(Bacillus anthracis).*

Since the **anthrax (*Bacillus anthracis*)** mailing attacks on a few recipients in the United States in 2001, no other attacks have been reported (CDC, 2016g). These unfortunate mail recipients contracted the bacillus either cutaneously or inhalationally. Cutaneous anthrax contractors developed erythema (red, inflamed area similar to cellulitis) on exposed areas of the hands, arms, or face that later transformed into painful vesicles and then necrotic painless, depressed, black eschar. Inhalation anthrax contractors had fever, dyspnea, cough, and chest discomfort (CDC, 2016h). Usually, respiratory failure and hemodynamic collapse will follow. Other symptoms may include lymphangitis and painful lymphadenopathy. It is recommended that individuals receive a complete treatment of ciprofloxacin, levofloxacin, doxycycline, or penicillin for 60 days (Hendricks et al., 2014). Vaccines against anthrax have been developed, and evidence shows that they can be effective in preventing the disease (Wright et al., 2014). The CDC (2016i) and its

partners are working collaboratively to develop more effective anthrax vaccines. Questions and answers about anthrax vaccines can be found at http://www.cdc.gov/vaccines/hcp/vis/vis-statements/anthrax.pdf.

Smallpox *(Variola major).*

It is believed that **smallpox (*Variola major*)** was eradicated in 1977. However, there are fears that a strain kept in a laboratory could be used as a bioweapon. According to the CDC (2016j), however, the United States has enough vaccines for everyone if needed. The side effects from smallpox vaccination mostly involve a mild fever, soreness in the injection area, and enlarged glands in the armpit (CDC, 2016k). In rare circumstances, severe side effects may occur and need medical attention. To learn more about potentially serious and life-threatening side effects, visit https://www.cdc.gov/smallpox/vaccine-basics/vaccination-effects.html.

Smallpox symptoms usually resemble influenza symptoms, which include fever and myalgias, followed by a rash. Rashes in smallpox can be differentiated from those of chickenpox (varicella). A rash from smallpox is most prominent on the face and extremities with the same stage of lesion development. A rash from chickenpox is more prominent on the trunk, with different stages of lesion development and resolution. The CDC (2016l) provides an acute, generalized vesicular or pustular rash illness testing protocol in the United States. The CDC (2016q) also provides an on-line assessment of a rash as a way to identify whether or not the rash is an indicator of a smallpox infection.

Category B Diseases/Agents

Category B diseases/agents are those that pose the second highest risks for world and national security. They include brucellosis; food safety threats (e.g., *Salmonella* sp., *Escherichia coli* O157:H7, *Shigella*); glanders; melioidosis; psittacosis; Q fever; ricin toxin; staphylococcal enterotoxin B; typhus fever; viral encephalitis; and water safety

threats (e.g., *Vibrio cholerae*, *Cryptosporidium parvum*).

Category C Diseases/Agents

Category C diseases/agents are emerging pathogens that could be reproduced for mass dissemination. They include emerging infectious diseases such as Nipah virus and hantavirus.

Epidemic and Pandemic Alert and Response

The CDC has created a public health emergency response guide to help public health professionals at the state, local, and tribal levels respond to an emergency in the first 24 hours. Health care providers should be alerted to any unusual symptoms indicative of an infectious outbreak related to bioterrorism. In turn, if a bioterrorist action is suspected, health care providers should report it to their local or state health department. According to the CDC (2016f), indications of bioterrorism include "an unusual temporal or geographic clustering of illness (e.g., persons who attended the same public event or gathering) or individuals presenting with clinical signs and symptoms that suggest an infectious disease outbreak (e.g., more than two persons presenting with an unexplained febrile illness associated with sepsis, pneumonia, respiratory failure, or rash or a botulism-like syndrome with flaccid muscle paralysis, especially if occurring in otherwise healthy persons); an unusual age distribution for common diseases (e.g., an increase in what appears to be a chickenpox-like illness among adult persons, but which might be smallpox); and a large number of cases of acute flaccid paralysis with prominent bulbar palsies, suggestive of a release of *botulinum* toxin." To learn more about clinical diagnosis, management, and responses to bioterrorism, refer to the CDC website at https://emergency.cdc.gov/bioterrorism/ and http://www.cdc.gov/mmwr/preview/mmwrhtml/mm5041a2.htm.

At the international level, responses to bioterrorism have also been prepared. WHO is a core organization responding to the needs for such preparation at this level. WHO works collaboratively with agencies in many countries to gather reports of suspected outbreaks

and rumors regarding bioterrorism through advanced technologies from all sources available, both formally and informally.

The Global Public Health Intelligence Network, a significant source of informal information related to outbreaks, was also collaboratively established by Health Canada and WHO. Its multilingual capabilities are Internet based, constantly searching data worldwide to identify information regarding disease outbreaks that can place international public health sectors at risk (WHO, 2016d).

The 2005 International Health Regulations—legally-binding regulations across countries led by WHO—are embraced by most nations throughout the world. Their mission is to provide legal frameworks to ensure health security among nations without unnecessary international traffic and trade interference (WHO, 2016e). To learn more about the International Health Regulations, see WHO (2016e).

Natural Disasters

Natural disasters have existed since Earth was formed. They are phenomena that occur through natural forces involving land, air, or water, and they often have large-scale negative impacts on humans who live in the affected areas. Examples of natural disasters include tsunamis, earthquakes, floods, landslides, mudslides, tornadoes, hurricanes, cyclones, typhoons, wildfires, volcano eruptions, extreme heat, and winter weather (CDC, 2016m). Natural disasters in recent decades have been reported to cause more harm in developing countries than developed countries, attributable in part to deforestation and inadequate warning and emergency management systems (Cameron & Shah, 2015). Health care professionals should be aware of recent large-scale natural disasters and be familiar with their negative impact on human well-being. Critically, lessons learned from the successful or unsuccessful management of these disasters should be shared among health care professionals so as to appropriately address and minimize the effects of future disasters.

Effects of Natural Disasters on Human Well-Being

All humans are affected by natural disasters economically, physically, and psychologically. In 2014, 317 natural disasters were reported around the world, which affected 94 countries. This means 107 people were affected by disasters around the world, and 8186 deaths were caused by these disasters. For example, 58 million people were affected by floods and storms in China (International Federation of Red Cross and Red Crescent Societies, 2015).

Concerning the physical effects of natural disasters, victims tend to have limited access to essential infrastructures for survival related to food, water, shelter, and sanitation. These deficiencies can lead to infections and undernutrition (Kouadio et al., 2012). Undernutrition, in turn, can lead to malnutrition and starvation—especially among infants and children in low-resource countries (Food & Agriculture

Organization, 2016). Infection outbreaks commonly diagnosed after natural disasters during the period from 2000 to 2011 included diarrhea, acute respiratory tract infections, viral hepatitis, and snail and trematode infections (Kouadio et al., 2012)

In terms of the psychological impact of natural disasters, PTSD is a classic negative effect that occurs among victims of all ages. Natural disasters can cause a significant amount of stress, especially from the loss of loved ones (Bread, 2014). A survey of flood victims in 2000 in Hunan province, China, showed that PTSD among the victims still existed 13 years later. No relationship was found between demographic characteristics and the recovery from PTSD (Hu et al., 2015). A follow-up study in China among 1573 adolescent survivors at 6, 12, 18, and 24 months after an earthquake found that negative life events, less social support, and less positive coping were common predictors of poor recovery (Fan et al., 2015). A cross-sectional study of 350 survivors from the Mount Merapi volcanic eruption in Indonesia reported that female adults aged between 18 and 59 years, and individuals who owned their own home experienced the highest levels of negative psychosocial impact (Warsini et al., 2015). In conclusion, psychological trauma has been reported as a result of natural disasters regardless of age or country of residence.

Natural Disaster Responses and Preparedness

In general, immediate medical care and rapid emergency response are important to address natural disasters, especially among children and women. Unfortunately, such care and response are reported to be inadequate regardless of the country type. However, the inadequacy of emergency care is heightened in developing nations (Zhong et al., 2014). For example, with the 2010 earthquake in Haiti, more than 200,000 people lost their lives, with 1.5 million people losing shelter (Thomson Reuters Foundation, 2015). As the poorest country in the Western world, Haiti already had limited resources before the earthquake. As many as 40% of rural Haitians did not have access to primary health care before the disaster, and 70% of health provisions in Haiti overall before the disaster were offered by NGOs (Gelting et

al., 2013). Although psychiatric mental health needs surged after the earthquake, existing mental health services in Haiti were damaged by the two crumpled, understaffed psychiatric hospitals as a consequence of the earthquake.

The psychiatrist-to-person ratio was 0.2 to 100,000 before the earthquake, and this ratio became worse when some health care workers were among the injured (WHO, 2016f). Vodou, a common belief about magic and illness in Haiti, is deemed by some to function as the main Haitian health care system (McAlister, 2016). Vodou beliefs might be considered by some professionals as a hindrance to modern mental health acquisition. Yet evidence shows that if a strong collaboration is established between traditional healers and health care providers, mental health services can be enhanced in the process (Khoury et al., 2012).

International Standard Guidelines for Emergency Mental Health Response

Before 2007, there was a lack of consensual international guidelines for emergency mental health response (WHO, 2016g). However, after the Asian tsunami in 2004, a taskforce was established composed of both governmental and nongovernmental experts from more than 100 various organizations and 27 different countries (WHO, 2016g). This taskforce, the Inter-Agency Standing Committee (IASC), developed the 2007 "IASC Guidelines on Mental Health and Psychosocial Support in Emergency Settings," reflecting standards for appropriate emergency mental health care for victims around the world (WHO, 2016g). The IASC guidelines are consistent with WHOs recommendations for emergencies among developing nations in that all victims and affected families should have access to emergency assistance with equality and dignity, and that helping people to remain resilient after a disaster is important. Besides these general principles, the minimum response for primary care clinics to help victims with severe psychological needs is outlined by the IASC and includes 10 major tenets (WHO, 2016g):

- Each victim is assessed holistically.
- Each victim will have access to essential psychiatric drugs.
- At least one emergency primary health care (PHC) professional is available to tend to victims' mental health in the affected area.
- The care provided by the PHC professional is adequately supervised.
- PHC professionals will be assigned to specific trainings and will not be overwhelmed by unnecessary training sessions.
- Additional mental health service points will be established for victims' accessibility.
- Unnecessary duplicating services should be avoided.
- All people affected by a disaster are informed about available mental health services.
- Primary care clinics should work collaboratively with local community agencies to discover, visit, and help the target population.
- Primary care clinics should have a major role in collaboration with other mental health agencies.

To learn more about the IASC's guidelines and related work, see WHO (2016g).

Emergency Management for Infants in Developed Countries

Most infants in developing countries are breastfed. Thus when natural disasters occur, they tend to do better than infants in developed countries because their mothers have mobile fresh milk supplies for them as long as they are with their mothers during the disaster (Gribble & Berry, 2011). Infants in developed countries whose primary food is based on formula feeding can be vulnerable because of a lack of supplies during a disaster (Gribble & Berry, 2011). Therefore emergency preparedness for these infants should be in place. In general, it is recommended that a week's supply of necessary items is

available for infants. For exclusively breastfed infants, 100 diapers and 200 wipes are the only items needed. For bottle-fed infants, more items are recommended for their survival (Gribble & Berry, 2011). Mothers of infants with ready-to-use formula will need the following items: 56 single servings of the formula, 84 L of drinking water, 56 feeding bottles or cups, 56 zip-lock plastic bags, a large storage container, a small bowl, a metal knife, 120 antiseptic wipes, detergent, 200 sheets of paper towels, 100 diapers, and 200 wipes (Gribble & Berry, 2011). Mothers of infants with powdered infant formula will need the following items: 2 cans of infant formula, 170 L of drinking water, a feeding cup, a large storage container, a measuring cup, a large cooking pot with a lid, a kettle, a gas stove, a box of matches/lighters, 14 kg of liquid cooking gas, a metal knife, a pair of metal tongs, 120 antiseptic wipes, detergent, 300 sheets of paper towels, 100 diapers, and 200 wipes (Gribble & Berry, 2011). Health care professionals who care for mothers with their infants should be trained to provide appropriate information to the mothers based on their feeding strategy.

The Office of Public Health Preparedness and Response provides very helpful information about the steps and types of emergency responses on the CDC website (CDC, 2012d).

Implications

The health-promotion and disease-prevention priorities that have been outlined in this chapter present challenges and opportunities for health care providers—as individuals and as a collective profession—to play key roles in emerging systems emphasizing health promotion and disease prevention. The goals for optimal health of individuals include greater longevity and quality of life, while decreasing sex, racial, and ethnic disparities (Purnell, 2008). The principles of primary prevention, health care policies, cultural diversity, cultural competency, and multidisciplinary teamwork in health promotion are critical to a new era that strives to achieve dramatic changes in health care delivery (Purnell, 2008). Through a perspective on the development of community-based, health-promotion programs, health care professionals can bring a balance to decisions that will be made about the appropriate use of traditional and newer health care resources (Box 25-4: *Healthy People 2020*).

Box 25-4

Healthy People 2020

Topic Area: Genomics

- To increase the proportion of women with a family history of breast and/or ovarian cancer who receive genetic counseling. (In 2005, 23.3% of US females with such a history obtained genetic counseling. The target for 2020 is 25.6%.)
- To increase the proportion of individuals with newly diagnosed colorectal cancer who receive genetic testing to identify Lynch syndrome (or familial colorectal cancer syndromes).

Topic Area: Global Health

- To reduce the number of cases of malaria reported in the United States. (In 2008, 1298 new cases of malaria were reported in the United States. The target for 2020 is 999 new cases.)

- To decrease the tuberculosis (TB) case rate for foreign-born individuals living in the United States. (In 2008, 20.2 cases of TB per 100,000 population were reported for foreign-born individuals living in the United States. The target for 2020 is 14.0 cases per 100,000 population.)

- To increase the number of global disease detection regional centers (GDDRCs) worldwide to detect and contain emerging health threats. (In 2009, seven GDDRCS were active. The target for 2020 is to have 13 active GDDRCs.)

- To increase the number of public health professionals (PHPs) trained by global disease detection (GDD) programs worldwide. (In 2009, 37,132 PHPs were trained by GDD programs. The target for 2020 is to have 144,132 trained by GDD programs.)

- To increase diagnostic testing capacity in host countries and regionally through the GDDRCs. (In 2009, 154 tests were established or substantially improved by GDD programs. The target for 2020 is 264 established/substantially improved tests.)

Topic Area: Health Care–Associated Infections

- To reduce central line–associated bloodstream infections. (In 2006–08, a standardized infection ratio of 1.00 was reported. The target for 2020 is a standardized infection ratio of 0.25, a 75% reduction.)

- To reduce invasive HA-MRSA infections. (In 2007–08, 26.24 infections per 100,000 persons were reported. The target for 2020 is 6.56 infections per 100,000 persons, a 75% reduction.

Topic Area: (Selected) Health Communication and

Health IT

- To increase the proportion of individuals who report that their health care professional (HCP) always listened carefully to them. (In 2007, 59% of individuals reported that their HCP always listened carefully to them. The target for 2020 is 65%.)

- To increase the proportion of individuals who report that their HCP always explained things so they could understand them. (In 2007, 60% of individuals reported that their HCP always explained things so they could understand them. The target for 2020 is 66%.)

- To increase the proportion of individuals who report that their HCPs always involved them in decisions about their health care as much as they wanted. (In 2007, 51.6% of individuals reported that their HCPs always involved them in decisions about their health care as much as they wanted. The target for 2020 is 56.8%.)

- To increase the proportion of individuals who use the Internet to keep track of personal health information, such as care received, test results, or upcoming medical appointments. (In 2007, 14.3% of individuals reported using the Internet to keep track of personal health information, such as care received, test results, or upcoming medical appointments. The target for 2020 is 15.7%.)

- To increase the proportion of individuals who use the Internet to communicate with their provider. (In 2007, 13.6% of individuals reported using the Internet to communicate with their provider. The target for 2020 is 15.0%.)

- To increase the proportion of individuals with access to the Internet. (In 2007, 68.5% of individuals reported having access to the Internet. The target for 2020 is 75.4%.)

- To increase the proportion of individuals with broadband access to the Internet. (In 2007, 75.6% of individuals reported having

broadband access to the Internet. The target for 2020 is 83.2%.)

- To increase the proportion of individuals who use mobile devices. (In 2007, 6.7% of individuals reported using mobile devices. The target for 2020 is 7.7%.)

- To increase the proportion of adults who report having friends or family members with whom they talk about their health. (In 2007, 79.5% of adults reported having friends or family members that they talk to about their health. The target for 2020 is 87.5%.)

- To increase the proportion of on-line health information seekers who report easily accessing health information. (In 2007, 37.3% of on-line health information seekers reported easily accessing health information. The target for 2020 is 41.0%.)

- To increase the proportion of medical practices that use electronic health records. (In 2007, 25.0% of medical practices reported using electronic health records. The target for 2020 is 27.5%.)

Topic Area: Selected Preparedness

- To reduce the time necessary to activate designated personnel in response to a public health emergency. (In 2009, 66 minutes was needed for designated personnel to report for immediate duty with no advance notice. The target for 2020 is 60 minutes.)

- To increase the proportion of Laboratory Response Network (LRN) biological laboratories that meet the proficiency standards for category A and category B threat agents.

- To increase the proportion of LRN chemical laboratories that meet the proficiency standards for chemical threat agents. (In 2008, 92% of LRN chemical laboratories met the proficiency standards for chemical threat agents. The target for 2020 is 95%.)

- To reduce the time for state public health agencies to establish after-

action reports and improvement plans following responses to public health emergencies and exercises. (In 2009, 46 days were required for state public health agencies to establish such reports and plans. The target for 2020 is 41 days.)

From US Department of Health and Human Services. (2010). *Healthy People 2020.* Washington, DC: US Government Printing Office.

Ten **essential public health services** as proposed by the CDC (2014) were developed in 1994 by the Core Public Health Functions Steering Committee, comprising representatives from various US Public Health Service agencies and other key public health organizations. This framework can be instrumental for health care professionals in various fields and can be applied at all levels, ranging from local to international. The 10 essentials include:

- Monitoring the health status of individuals and communities so as to address identified health problems
- Diagnosing and investigating health problems and health hazards among individuals in the community
- Informing, educating, and empowering people with regard to health problems and various ways to address the problems, including applying strengths found in the community
- Mobilizing community partnerships and community actions so that health problems can be identified and addressed
- Developing policies and plans that will assist individuals and their communities to address identified problems
- Enforcing laws and regulations to provide and protect the safety and health of individuals and communities
- Linking people to appropriate health services to ensure accessible health care
- Ensuring proficient personal and public health care workforces
- Evaluating the accessibility, effectiveness, and quality of health services
- Searching for innovative ideas and solutions to identified health

problems

For more information about the 10 essentials, see CDC (2014). These 10 essentials—along with an awareness of human rights, empowerment, cultural diversity, and cultural competence (Box 25-5: Diversity Awareness)—can help health care professionals effectively deliver care to individuals and communities. It is important, moreover, to help individuals, families, and communities become active participants in defining their own health needs, in making informed decisions to meet those needs, and, ultimately, in bringing about real improvements in their own health status and quality of life.

Box 25-5

Diversity Awareness

Health and Health Promotion in a Native American Tribe: The Navajo

The Navajo people of the *Dine Bikeyah* live on a vast land in which the four states of Arizona, Utah, New Mexico, and Colorado intersect. The Navajo hold this land as sacred and as an integral part of their lives. They believe that health is a part of the *hozho'*, which is a personal sense of well-being and rightness with the world and is all-inclusive. For the Navajo, health is not separate from the overall state of balance among the body, mind, spirit, and the surrounding environment. When one of these is out of balance, *hozho'* is not achieved. *Hozho'* is everything that a Navajo thinks of as being good, in terms of good and evil or favorable and unfavorable. The Navajo strive to maintain *hozho'* and to live in harmony with all things that surround them. The goal of Navajo life in this world is to live to attain maturity with *hozho'* and to die of old age, the result of which incorporates beauty, harmony, and happiness or *sa'ah naagh"ii bik'eh hozho'*. When the body, spirit, or mind fall out of *hozho'*, a traditional healer or medicine man is sought. In many instances, the medicine man recommends that the individual seek both Western medicine

and the traditional ways to cure the problem.

Since 1955, trends in Navajo health have demonstrated a progressive improvement, particularly in the areas of maternal and infant mortality. However, on the increase are lifestyle-related diseases and premature deaths, for which health-promotion activities can have an effect. Among these lifestyle-related diseases are adult-onset diabetes, AIDS, and alcohol and substance abuse. Health care providers who work with the Navajo must address all health-promotion and disease-prevention activities in terms of an appreciation for the cultural and economic realities and the needs of this community.

From The Official Navajo Nation Visitor Guide. (2017). Navajo cultural history and legends; Anonymous. (n.d.). Navajo land. http://www.discovernavajo.com.

An increasing demand for primary health care providers will continue to spur the need for more advanced practice nurses, including nurses with degrees of doctor of nursing practice and doctor of philosophy. This demand can be met if undergraduate students are introduced early to concepts of health promotion and disease prevention with an emphasis on evidence-based practice, human rights, cultural diversity, and cultural competency, and with a global perspective (Purnell, 2008). In this way, health promotion, quality of life, and socioeconomic justice might become increasingly valued in cultures throughout the world.

In addition, health care educational programs in culturally diverse global frameworks that teach about malnutrition, emerging diseases, HIV/AIDS, bioterrorism, violence, and other contemporary challenges will help nurses and other professionals play innovative roles in health care and maximize the quality of life around the world. Faculty and students will ideally increase their work together in interdisciplinary teams, using an expanding variety of health-promotion services and guided by national and international standards. Given the increasing focus on cultural diversity and self-care in disease prevention and health promotion, nurses can respond directly to the health needs of individuals, families, communities, and

groups by focusing on health promotion and disease prevention tailored to particular cultures and spiritual beliefs and by supporting new ways to work and live.

In the area of research, understanding health care practices and the impact of culture on people from different nations will enable health care professionals to create appropriate health-promotion and disease-prevention interventions. Thus international collaborative research is important. Sex and age disaggregated data quantitative and qualitative analysis needs to be used more widely in research so that data can be categorized by sex and age/age group, which will allow examination and identification of needs that are specific to each sex and age group (Mazurana et al., 2011). Sex and age disaggregated data could be especially beneficial in the assessment of crisis situations such as bioterrorism and terrorism because they help to identify the immediate needs of particular groups, the reasons they need immediate help, and the resources that can be most helpful (Inter-Agency Standing Committee Gender Sub-Working Group, 2009).

To be advocates for newly emerging priorities for disease prevention and health promotion, nurses in the 21st century need to engage in the following:

- Participate in policy development for health promotion as the health care of individuals in acute settings shifts from hospitals to home and community settings. Thus the attention to health-promoting behaviors in home and community environments provides an entry point for the development of models of primary care that emphasize both health promotion and disease prevention in communities.
- Influence public expectations about health promotion. Presentations and other forms of public dialogue and education will help raise awareness of the value of individual and community health promotion. Nurses have the collective capacity to change the philosophy of the system from selling health care in the marketplace to creating a milieu for changing health behaviors. Encouraging meaningful community participation in addressing health issues provides a significant opportunity to narrow the gap between what is possible in terms of health promotion in each country and what is

reality. As mentioned earlier, violence and emerging diseases are among the challenges today that require heightened public awareness.

- Promote equitable access to preventive health care. Given the higher rates of preventable conditions among populations in resource-poor countries, a need to promote the justified distribution and utilization of preventive health services is apparent. Community-based efforts that combine public and private resources should be targeted to those most in need of health care. Delivery models that focus on integrating preventive and primary care should be expanded.

Preventive health care delivery should be based on broad research agendas that encompass multiple health and social science perspectives. Health care providers should participate in areas of research that will cost-effectively influence both personal and community health. Service delivery can also benefit from expanded health service research agendas that foster collaboration among disciplines and countries. Most important, preventive health care should be adapted to the health and social problems of specific groups and cultures. Alternative approaches to health-promotion and preventive service delivery should be used where they are most effective to meet new international health challenges, including mobile vans, school and work site clinics, and other community-based, collaborative actions (Box 25-6: Innovative Practice).

Box 25-6

Innovative Practice

Haitian Health Foundation: A Charitable Outreach to Neighbors in Need

A volunteer effort of health professionals initiated in Haiti in 1982 by Dr. Jeremiah Lowney and his wife, Virginia, has grown into an outpatient health care facility supported by a nondenominational foundation called the Haitian Health Foundation (HHF). In 1985,

after working for 4 years in Port au Prince, HHF moved its outreach to Jeremie, Haiti, at the suggestion of Mother Teresa of Calcutta, to bring health care, hope, and opportunity to this especially poor and remote area. The clinic at Jeremie employs 105 people, including 2 full-time physicians, 1 full-time dentist, 10 registered nurses, 2 licensed professional nurses, a medical technician, a dental assistant, and 70 to 80 auxiliary personnel (all Haitians). The clinic provides health care to more than 120,000 Haitians yearly (Haitian Health Foundation, 2016).

The Haitian Agents de Sante program currently employs villagers in 936 villages surrounding Jeremie. This program was initiated by a nurse who enlisted an individual who had a seventh grade education in each village. After being educated in health promotion, the person became the health agent of that village. These health agents are trained by HHF to provide preventive and basic health care and education. Many villages have also begun mothers' groups, by which women can share experiences and knowledge relating to nutrition, health care, and other topics that have an effect on their quality of life. Breastfeeding classes and immunization programs are available.

Another program was begun by the building of a food distribution pavilion. This building will be used to store and distribute food to more than 1000 children and pregnant women three times a week. The pavilion will also be used to educate participants in nutrition and preventive health care. Much of the education in these programs is accomplished through song, primarily because this approach appears to enable the Haitians to remember what is being taught.

For more than 8 years, another education program has provided access to schools for poor children in a country in which education is neither free nor mandatory. In 2016, almost 3300 students attended school through this program. Tuition, uniforms, books, and shoes are provided by HHF funds or through the Save-a-Family Plan.

HHF relies heavily on the generosity of donors and the many volunteers who donate their time and talents to supplement the staff in Haiti. Volunteers travel to Jeremie at their own expense from the United States, Canada, and Europe to share their skills and resources

with the poor. These volunteers include health care providers, electricians, plumbers, teachers, clergy, and students.

These programs are only a few examples of the health-promotion programs sponsored by HHF. These efforts show how dedicated professionals can make a difference, even in third world countries in which health care resources are rare.

Case Study

Nutrition: Don

Don is a 4-year-old boy who is brought to a rural health department clinic by his grandmother. Don and his family are recent immigrants from Laos and have lived in this area for less than 1 year. This is Don's first visit to the clinic. Don looks weak, with sunken eyes and a dry mouth. His weight is less than 70% (or less than three standard deviations) of the median weight for height, and he has underdeveloped buttocks, thighs, and upper arms. Through a translator, Don's grandmother tells the community health nurse that Don has had diarrhea for more than 2 days and that the family can barely "make ends meet." Don's parents are seasonal farmworkers and are at work today.

Reflective Questions

- Who is Don's caretaker during the day?
- How can the nurse help Don's family learn about the resources available in their community?
- Where does the nurse direct Don's family for immediate help?
- How would the nurse follow up with the family to prevent further problems with this child?

Care Plan

Nutrition: Don

***NURSING DIAGNOSIS: Imbalanced nutrition—less than body requirement related to inadequate food intake and diarrhea as evidenced by a weight of less than 70% (or less than three standard deviations) of the median weight for height; underdeveloped buttocks, thighs, and upper arms; and sunken eyes and dry mouth**

Defining Characteristics

- A weight of less than 70% (or less than three standard deviations) of the median weight for height
- Underdeveloped buttocks, thighs, and upper arms
- Sunken eyes, dry mouth, and a history of diarrhea

Related Factors

- Poverty, lack of knowledge about available resources

Short-Term Expected Outcomes

The grandmother will:

- Increase health-promotion and health-maintenance knowledge regarding Don's nutrition
- Increase health-promotion and health-maintenance practices regarding Don's nutrition
- Gain access to available resources, such as Food Stamps and the Special Supplemental Nutrition Program for Women, Infants, and Children

Long-Term Expected Outcome

- Don will show no signs of malnutrition.

Interventions

- Give Don fluids/food per protocol.
- Observe Don's fluid/food intake and monitor his signs and symptoms.
- If necessary, refer Don to an appropriate health setting.
- Assess the grandmother's knowledge and practices regarding Don's nutrition.
- Educate the grandmother about the negative effects of malnutrition on Don's growth and development.
- Educate the grandmother about appropriate food choices for Don.
- Assist the family to access and connect with available nutrition community resources.
- Assist Don's parents to access the community career center.
- Provide follow-ups to monitor Don's physical progress (body weight for age and height) and family's access to available resources.

*NANDA Nursing Diagnoses—Herdman T. H. & Kamitsuru, S. (Eds.). Nursing Diagnoses–Definitions and Classification 2015–2017. Copyright © 2014, 1994–2014 NANDA International. Used by arrangement with John Wiley & Sons Limited. In order to make safe and effective judgments using the NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Summary

This chapter has presented priority issues and future directions for health professions in the areas of health promotion and disease prevention from a world perspective. Current emerging health care reform efforts pose significant challenges and opportunities for health care providers, educators, and researchers, with the emphasis on human rights, cultural diversity, and cultural sensitivity; health promotion and disease prevention; evidence-based practice and advanced technology; and global perspectives. Nurses in the new millennium are required to have sufficient vision, expertise, and the ability to truly make a difference in the health of the people for whom they care at individual, local community, national, and international levels. Through leadership, creativity, and determination, nurses and other health care providers can establish a healthier future for people around the globe with a respect for human needs, cultural diversity, and human rights.
